This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

+ *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.

+ *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.

+ *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.

+ *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at `http://books.google.com/`

SCIENCE IN THE LAW-COURTS.

In *The Journal of Gas Lighting* for December 22nd we find an article entitled "The Institution in the Strand." We have certainly no proof that the writer is referring to the discussion raised by *Nature* and continued in the CHEMICAL NEWS; but that he should have selected the present time for making known his opinions is, at least, a curious coincidence. His object seems to be a defence of our present system of coming at the truth, or of something which may serve in its stead, whenever a scientific or a technical issue is raised in the law-courts. He considers the new Courts of Justice as being "besides the Forum of the nation its supreme Temple of Arts, Sciences, Literature, and Humane Culture!" Lest we should be suspected of laying too great emphasis upon a single passage, detached possibly from modifying clauses, we make further citations:—"This building in the Strand is more of an educational institution than the Royal Society, the British Association, the Institution of Civil Engineers, and all the other learned societies of the kingdom put together." And again:—"Truly the greatest teaching university in the world is this in which there are no professors, tutors, or classes, and where everybody is admitted to learn as much as he likes or can retain of the instruction provided at other people's expense." In developing this astounding claim the writer displays what, to us at least, appears an utter misconception of the functions and the results of our learned societies and our scientific journals, as well as of the character and the habits of scientific men. At the same time, by admissions which he makes, not reluctantly but gleefully, he confirms our view of the necessity for a thorough change.

In support of the charges which we bring we must point out that the Royal Society and "the other learned societies" are not, in any legitimate sense of the word, "educational institutions." Their function is not to diffuse or to popularise knowledge, but to discover what has never been known before. Each paper read before them is a step—great or small—in this direction. Now, in technical trials, the law-courts deal and can deal only with inventions,—special applications of what is already known. New discoveries are never announced from the witness-box. Says the writer:—"The law-courts after all are the scenes where the greatest triumphs of science are placed within the mental reach of the student." Nothing of the sort: the highest generalisations, epoch-making researches, do not come within the purview of the courts at all. Whoever heard of the doctrine of organic evolution, the atomic theory, the cosmogony of Laplace, the law of continuity, the conservation of energy, or the like, being bequibbled in a court for the edification of a bewildered jury? What occupy the attention of courts are incidental matters, such as telephones, torpedoes, and gas-engines—to take the writer's own instances—things which, however grave in a pecuniary sense, are but as the crumbs that fall from the table of science.

The writer considers that "the most striking difference between the handling of technical subjects in the law-courts and in meetings of learned societies is the length of time considered necessary in these cases." True, but this difference is due not to the thoroughness of the courts, but to a circumstance which escapes the writer altogether. A *savant* reading a paper before a learned society speaks of a subject with which he is thoroughly acquainted at first hand. He speaks to men familiar with the same kind of researches,—men who know how the new discovery announced fits in with what is already established, and who can judge of the value of the evidence adduced. In the law-courts all this is reversed; everything has to be explained to men who have little or no previous knowledge of the subject, and whose training unfits them for its right appreciation.

Let us note the derogatory opinions here put forward concerning scientific men:—

"The great man may ordinarily, in his orations and papers, take advantage of his position and reputation, and circulate rubbish that would ruin an unknown speaker; but when once he is fixed by the keen eye of Mr. Attorney-General, or some of his professional brethren, he must talk sense, if he can, like any other man."

Or again:—"The writer of a paper is allowed to take up any position that pleases him, and to say as much or as little as he thinks best for the support of his own views; and after all his hearers are under a certain obligation to him, which generally disposes them to handle him gently."

Surely the writer of the article before us ought to know that any statement made in the Transactions of our learned societies at once goes the round of the civilised world, and is tested and re-tested in a hundred laboratories,—an ordeal far more searching than any verbal cross-examination. And if the fact cannot be verified, or if the inference cannot be maintained, the refutation never fails to be published. To "circulate rubbish," ordinarily would prove a hazardous experiment for the most eminent.

One more quotation, and we have finished:—"The pleasure becomes rapt excitement when . . . the leader on the other side calmly takes the Professor back over his statements, and, regardless of his agonised writhings, makes him confess to an unwarranted assumption here, and a blunder there, and a slip of memory in half-a-dozen places."

A main difficulty with which the expert has to grapple

is that frequently a large part of the evidence by which he reaches his conclusions cannot be expressed in words, though it could easily be pointed out to another expert in consultation. Those "unwarranted assumptions, blunders, and slips," of which our unknown friend speaks, are simply the outcome of the system of examination and cross-examination. Let this system be done away with,—let experts be no longer the partizans of the litigants, but the impartial advisers of the Court,—and those unseemly exhibitions which throw our friend into "rapt excitement" will be at an end, and the "tremendous cost" to the litigants will be seriously reduced.

POTASSIUM CHLORIDE AS A PLANT POISON. ESSENTIAL ELEMENTS OF PLANTS.

By J. M. H. MUNRO.

ONE of the most interesting points in Mr. Jamieson's article on "The Essential Elements of Plants" (CHEM. NEWS, vol. lii., p. 287), is the proof, incidentally afforded by some of his experiments, that potassium chloride may act as a plant poison. Mr. Jamieson appears to have experimented for three successive years on the application of different potash salts to peas and turnips. In the first year the only striking result was produced by potassium chloride, which absolutely reduced the yield to nil in each case; potassium carbonate and sulphate, on the other hand, appeared to be beneficial, since larger crops were produced than when potash was withheld altogether. In the second year the peas again suffered severely from the action of potassium chloride, but the turnips largely benefited from this and from the other potash salts tried. In the third year potassium chloride produced strikingly good results on both peas and turnips, in common with the other potash salts. In the cases where potassium chloride was injurious, Mr. Jamieson tells us that "the plants were actually killed, the symptoms being such as directly pointed to the action of free chlorine. The leaves were markedly blanched throughout in an early stage of growth, and ultimately the plants died"—and then follows theorising to the effect that "decomposition of the potassium chloride had taken place, probably within the plant, the plant seizing the potassium which was essential to it, and liberating chlorine, which exerted its bleaching and poisonous influence." In Mr. Jamieson's 1882 Report to the Sussex Association these theories are pursued further. Nitrate of soda having been found efficacious—in one or two cases—in counteracting the injurious influence of potassium chloride, this result is "explained by its soda neutralising the chlorine." Lime, which one would think as capable—or incapable—of "neutralising the chlorine" as soda, does not answer, because "successful counteraction means liberation of the counter-actor within the plant, and this simultaneously with the substance to be counteracted." "The useless matter, soda and chlorine, at once uniting, form harmless common salt." "Experience and experiment both seemed to indicate that black matter of soil is able to counteract that injurious action" (of potassium chloride). This is explained by the hydrogen of organic matter uniting with the chlorine, the hydrochloric acid thus formed "neutralising itself by lime or by other base at hand."* Acting on the hydrogen theory Mr. Jamieson dressed a plot with dextrine, to supply hydrogen and counteract the liberated chlorine—which it did not do. It gave, however, a transient deep green colour to the young leaves, which again is explained as possibly the effect of "unusually active" or "nascent" nitrogen liberated from nitrates by the action of soil bacteria in presence of the dextrin. This reduction of nitrates, pointed out by Gayon and Dupetit, takes place with extreme ease and rapidity under certain circumstances, as I have had repeated occasion to verify for myself, but as I do not know so much about the "unusually active" properties of the liberated nitrogen as Mr. Jamieson appears to, I have always regarded this reaction as one of the most serious causes of nitrogen being absolutely lost to the soil.

Whilst I cannot agree with Mr. Jamieson in attributing the blanching* and reddening of turnip leaves to chlorine and free acid liberated within the plant, and am unable to follow him in any of the ideas I have quoted above, the *fact* of the occasional injurious action of potassium chloride is certainly an interesting one. A striking instance of it occurred in some experiments on potatoes which I conducted last summer (1885), and may be placed on record here. The plots were on stiff soil at Kingswood, Gloucestershire; and in a field almost immediately adjoining excellent experimental crops of potatoes had been grown, in 1883 and 1884, with a mixed manure containing potash salts (kainite).—(*Agricultural Gazette*, October, 1884.)

Last summer the object in view was to test certain sewage manures in comparison with certain standard fertilisers. The sets were planted on March 17th, 3 feet apart each way, and partially covered with soil. A weighed quantity of manure was applied to each set on March 23rd, and the covering completed. The season was a very dry one in the early part, and the crop was consequently deficient in weight; the tubers were dug and weighed up at the end of September. Briefly summarised the results were as follows:—

39 sets, each manured with 3 ozs. Peruvian guano, gave 114 lbs. tubers (average of five rows).
39 sets, each manured with 2 ozs. cod-fish guano and potash, gave 102 lbs. tubers.
39 sets, each manured with 8 ozs. dried sewage sludge (Coventry), gave 86 lbs. tubers.
39 sets, each manured with 1 oz. herring fish guano and potash, gave 84 lbs. tubers.
39 sets, each manured with 2 ozs. "ferrous superphosphate," gave 82 lbs. tubers.
39 sets, each manured with 4 ozs. dried Coventry sludge, gave 76 lbs. tubers.
39 sets, each manured with 8 ozs. "native guano," gave 74 lbs. tubers.
39 sets, each manured with 1 oz. cod-fish guano and potash, gave 72 lbs. tubers.
39 sets, unmanured, gave (average of four rows) 64 lbs. tubers.
39 sets, each manured with 2 ozs. dried Coventry sludge, to which 20 per cent of potassium chloride had been added, gave no tubers. Only one or two plants appeared above ground, and these eventually dwindled away and died.

There are two curious circumstances in this case. One is that the herring and cod-fish guano, as sent out by Messrs. J. Jensen and Co., contains 12 to 40 per cent of potash, chiefly or partly in the form of chloride, yet these manures produced healthy plants and good crops. The other noteworthy circumstance is that the manure called "ferrous superphosphate" was in effect a mixture of calcium sulphate, monocalcic phosphate, and ferrous sulphate.

* Once or twice in using sulphate of potash, plants with sickly leaves were produced "reddened as if by free acid," thus "confirming the evil tendency of liberated sulphuric acid."—One does not quite see why sulphuric acid should not "neutralise itself by lime or other base at hand" as easily as hydrochloric acid.

* Blanched or variegated leaves generally imply the non-formation of the colouring-matter, which may be brought about by various causes. Salts of zinc, for example, are usually poisonous to plants, and the first symptom is a bleaching of the leaf tips. I have seen even oxide of zinc kill down all the foliage of a plant (*Viola tricolor*), and the new shoots and leaves which were at length produced, and which survived after a severe struggle, were half of them white. In another experiment a hardy plant of wood sorrel growing in a flower-pot was completely killed by a dose of sulphate of zinc. After some time 5 grains of wheat were sown in the earth of the same flower-pot; the plants all germinated and grew to the height of an inch or so, but were perfectly colourless, and died off because the formation of the green colouring matter was prevented by the [illegible].—J. M. H. M.

containing about 12 *per cent of green vitriol*, yet this, far from poisoning the plants, proved to be a good manure, and gave one of the best crops (considering that it was the only non-nitrogenous manure employed). The manures were in every case carefully distributed amongst the surface soil, and were separated from the tubers by an intervening layer of unmanured soil. I was prepared to expect a fair result from the "ferrous superphosphate," but I do not understand the action of the potassium chloride.

To turn to another subject. Mr. Jamieson now foreshadows "the exclusion of sulphur, magnesium, and calcium from the list of plant essentials," mainly on the strength of certain experiments recorded in his Report for 1882 (the *only* analyses quoted appear to be taken from that Report), and continued with less striking results in 1883 and 1884. Good turnips were grown in sand "practically destitute of plant food," notwithstanding that sulphur, calcium, and magnesium were omitted in turn from the manure used. But the turnips thus grown contained as much calcium and magnesium as when these elements were supplied in the manure, so that the sand was at any rate *not* practically destitute of these two substances. One can only agree with Mr. Jamieson (1882 Report) that "the plants manured without lime and magnesia had succeeded in imbibing lime and magnesia, and all inferences regarding these elements must be passed over in the meantime"; and with the further opinion expressed in the 1884 Report (p. 33), "it appears from this set of experiments that lime is required: as was frequently pointed out, the evidence against lime was not strong from the first." Why, then, does Mr. Jamieson now consider that these same experiments "foreshadow the exclusion" of lime and magnesia from the list of plant essentials? As regards sulphur, two turnips only—grown with a manure from which sulphur was excluded—appear to have been analysed: one contained sulphur, although less than the normal proportion; the other is said to have contained none. The only analysis I can find of the sand in which these roots were grown is on page 1, Appendix, of the 1882 Report, and we there find the proportion of sulphuric anhydride stated as 0·010 per cent of the dry soil, or 1 part in 10,000. As long ago as 1864 Berrier and Lucanus raised very fair plants of oats in well water containing less than this proportion of sulphur (7·5 parts SO_3 in 100,000), but no one has hitherto thought of inferring from this experiment that sulphur is non-essential to plant growth.

College of Agriculture, Downton, Salisbury.

A THEORY OF THE CONNECTION BETWEEN THE CRYSTAL FORM AND THE ATOM COMPOSITION OF CHEMICAL COMPOUNDS.*

By WILLIAM BARLOW.

IT is not my intention to discuss the generally received atomic theories, or to offer any new suggestions as to the nature of atoms. I shall merely require the following hypotheses as a basis for the theory I am about to submit to you:—

1. That atoms, or detached centres of force, exist, and that they in some cases attract, in some cases repel, one another.
2. That the atoms of a crystallising body, and by this I mean the atoms of the chemist, are kept in their places by the system of mutual attractions and repulsions which they exercise on one another.
3. That the repulsion or attraction, as the case may be, of any two atoms is some function of their distance, or mean distance, apart, and is irrespective of any linking together of particular individual atoms in molecules, if such ever really obtains.
4. That two atoms which when within a certain mean distance of one another are repelled, are attracted when at some greater distance apart.
5. (And this is the foundation-stone of my theory) that the attractions or repulsions exercised by *different kinds of atoms* are *different functions* of the distance.

These are my hypotheses: the following proposition is based upon them:—

If the different kinds of atoms composing a fluid mass are present in such numerical proportions as to admit of a uniform compact symmetrical arrangement in space of the different kinds of atoms with respect to one another, then the occurrence of alternate condensation and rarefaction of portions of the mass, such as is produced by passing wave-movements (those propagating sound, for instance), will everywhere produce an arrangement of the atoms having some degree of approximation to such a symmetrical arrangement.

The proof I have to offer is the following:—

It is evident upon the hypotheses I have stated that when any portion of a fluid mass composed of different kinds of atoms experiences condensation or rarefaction the atoms will from time to time take up relative positions such that the various attractions and repulsions subsisting at the moment form a system in equilibrium.

And since, by hypothesis, the attractions or repulsions exercised by *different kinds of atoms* are *different* functions of the distance, their arrangement will not generally be similar for different degrees of condensation.

If, however, the attraction or repulsion exercised by a certain atom on another atom is balanced by the attraction or repulsion of a similar atom *placed opposite at an equal distance*, the similar approach or recession of the two similar atoms will cause the forces they respectively exert on the third atom to neutralise one another, whatever the nature of the laws according to which the forces of attraction or repulsion change with change of distance.

To give a simple illustration. Suppose these five balls (Fig. 1) represent five atoms of some system in equilibrium (different kinds of atoms being indicated by different coloured balls), and that they have the symmetrical disposition you see; and suppose that through the passage of some wave of alternate condensation and rarefaction the distances apart of the atoms are similarly changed, that opposite atoms similarly approach, or similarly recede, from the central atom, then it is clear that, so long as the symmetry prevails, any change in attraction or repulsion produced by the alteration in position of one atom will be compensated by the similar change produced by the simultaneous alteration in position of the opposite atom.

But this will only be the case when the symmetrically placed opposite atoms *are of the same kind*. If two atoms *of a different kind* simultaneously approach a third atom in opposite directions, we shall, by hypothesis, have dissimilar changes in the degree of attraction or repulsion exercised by the two opposite atoms, *and the central atom will move nearer to one or other of them*, and the further the departure from a symmetrical arrangement the greater the change of relative position of the atoms will be.

It follows that the more symmetrically the various kinds of atoms of a liquid mass are placed with respect to one another, the less change of relative arrangement they will undergo under the condensation or rarefaction produced by passing waves.

Now, from the fact of the atoms experiencing less change of position the more symmetrically they are disposed, it evidently follows that the most symmetrical and compact distribution of the atoms in space possible will be the system of stable equilibrium towards which they will continually approximate under the re-arranging agency of the alternate condensations and rarefactions, and the more vigorous the re-arranging agency is the nearer the approximation to this symmetrical system of arrangement will

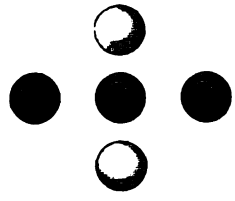
* A Paper read before Section B, British Association, Aberdeen Meeting.

be. The proposition which I just now submitted is therefore established.

In cases where more than one symmetrical compact system of arrangement of the same atom proportions is possible, it is reasonable to conclude that the system which, under the conditions prevailing, *gives the most stable equilibrium of the forces of attraction and repulsion* will be the symmetrical system towards which the atoms will approximate.

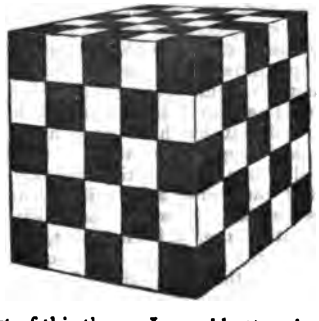
My theory, based on the foregoing, of the origin of the symmetrical disposition of the matter of crystals,—a disposition which is revealed both by their forms and their

FIG. 1.



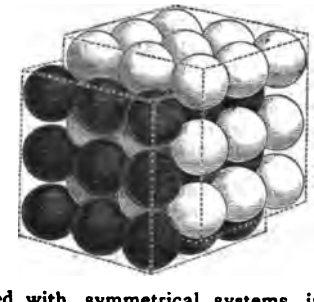
properties—is: *That liquid matter in the act of crystallising, just before solidification takes place, has the chemical atoms of different kinds which compose it symmetrically arranged in space with respect to one another, and that this symmetrical disposition of the atoms is the direct consequence of the continual condensation and rarefaction of different groups of the atoms of the mass produced by the passage of waves (such, for example, as those which propagate sound), and is that disposition which gives the greatest stability under the conditions prevailing.*

FIG. 2.



In support of this theory I am able to point out several cases in which, if the particular numerical proportions of different atoms occurring in certain bodies are arranged in the most symmetrical and compact manner possible, we

FIG. 3.



are furnished with symmetrical systems in complete harmony with the respective crystal forms of the bodies.

First, I will take the very simple case of compounds composed of two kinds of atoms in equal numbers.

There are but two systems of arrangement of *equal* infinite numbers of two sorts of *small* bodies in space which are completely symmetrical, and in which each sort is evenly distributed through space, the perfect evenness of distribution being evidenced by the property that when the centres of the bodies nearest to any body of the system are joined the solid thus outlined has its edges equal.

These two symmetrical systems may be exhibited in the following manner:—

Take a number of equal cubes of two different colours, say black and white, and proceed to build them into a con-

FIG. 4.

tinuous mass in such a manner that no cube shall touch any other cube of the same colour except at its edges, or, in other words, so that a section of the mass parallel to either of the three directions of the faces will present the appearance of a chess-board (Fig. 2); then—

1. If, disregarding the distinction of colour, we suppose a number of similar small bodies of one sort placed at the centres of all the cubes, and a number of similar small bodies of another sort placed at all the cube angles, we have an example of one of the two systems.
2. If we suppose a number of similar small bodies of one sort placed at the centres of the black cubes, and a number of similar small bodies of another sort placed at the centres of the white cubes, we have an example of the other system.

Here are two stacks of balls so arranged that the centres of the balls in one stack (Fig. 3) have the disposition of the first of these symmetrical systems, and the

FIG. 5.

centres of the balls in the other stack (Fig. 4) the disposition of the second. Both systems are symmetrical with respect to three axes at right angles to one another, and are evidently in harmony with a cubic form.

Now we have the important fact that, as a rule, compounds containing an equal number of atoms of two kinds crystallise in cubes. As instances I may mention potassic chloride, potassic bromide, potassic iodide, sodic chloride, sodic bromide, sodic iodide, cæsic chloride, plumbic sulphide, argentic chloride.

Mercuric sulphide which crystallises in six-sided prisms is an apparent exception, but if we were guided by the gaseous volume of mercury in determining its atomic weight we should have two atoms of mercury to one of

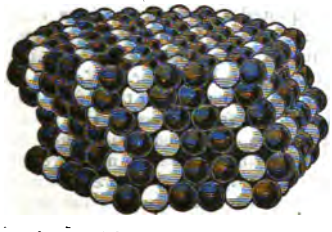
sulphur in this compound. Other apparent exceptions are zincic oxide crystallising in six-sided prisms, cadmium sulphide, and glucina.

The facts as to compounds of equal numbers of two kinds of atoms are therefore seen to be mainly in harmony with the theory I have submitted.

Next as to compounds composed of two kinds of atoms present in the proportions 1 : 2.

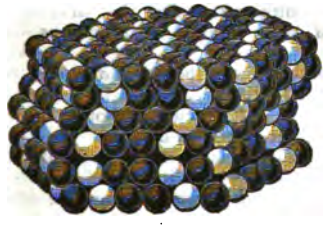
Infinite numbers of two sorts of similar small bodies present in the proportions 1 : 2 can evidently be arranged

Fig. 6.



in the same plane with perfect symmetry in the way I have here shown (Fig. 5),—one kind of body being placed at the centres of the black balls, the other at the centres of the white,—and series of these plane systems can be ranged parallel to one another in a symmetrical manner in various ways. There are, however, but six different ways in which a number of similar plane systems of this

Fig. 7.



kind can be placed so as to give complete evenness of distribution, as well as complete symmetry, each small body of these six systems being equidistant from the twelve bodies nearest to it.

These six systems are shown by the centres of the balls in these six stacks (Figs. 6, 7, 8, 9, 10, 11). All the six systems have the vertical distances between the plane systems the same.

Fig. 8.

In four (Figs. 6, 7, 8, 9) the arrangement of the different colours is symmetrical about a vertical axis or direction, balls of one colour forming staircase spirals about symmetrically-placed lines having this direction. In the other two (Figs. 10 and 11) the arrangement of the different colours is symmetrical with respect to three planes at right angles to one another.

Disregarding the difference of kind of the small bodies symmetrically arranged, we have two kinds of symmetry only; these three systems (Figs. 6, 7, and 10), when considered apart from the differences of colour, being identical; and these three (Figs. 8, 9, and 11) also identical.

Now at first sight we might suppose that the atoms of the compounds under consideration should have the arrangement of one or other of these six systems; but a moment's consideration of our hypothesis, that the attractions or repulsions exercised by the different kinds of atoms are different functions of the distance, shows us that the distance from an atom to the atoms next around it in one of the plane systems (Fig. 5) will not ordinarily be the same as the distance from an atom in one plane system to one of the nearest atoms in the next plane

Fig. 9.

system; for each atom will be exposed to different systems of repulsion and attraction in the two different directions. While, therefore, we shall expect the atoms of the compounds under consideration to be arranged approximately according to one of the six systems depicted, *so far as their situation relatively to a vertical axis is concerned*, we shall not look for the distances between the plane systems to be as in these six systems before you, but shall expect these distances, though equal to one another throughout the same system, to be different in different cases, according to the nature of the two kinds of atoms forming the compound.

Fig. 10.

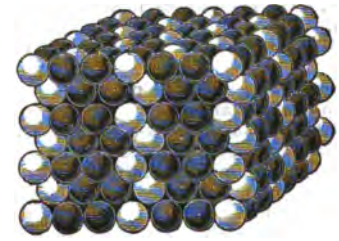


Fig. 11.

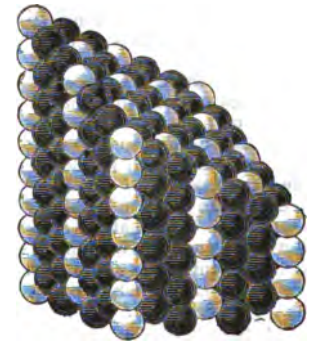

In other words, the arrangement of the atoms of a body composed of two sorts of atoms present in the proportion 1 : 2 may be expected to be such that, instead of its being depicted by one of these six stacks of equal spheres, it would be depicted by a similarly-formed stack composed of similar and similarly-placed spheroids or ellipsoids. In

the cases which follow those four of our six typical systems which are symmetrical about a single vertical axis (Figs. 6, 7, 8, 9) the arrangement would be depicted by a stack of similar prolate or oblate spheroids placed with their axes vertical. In cases which follow the remaining two systems (Figs. 10 and 11), whose symmetry is trimetric, the arrangement would be depicted by a stack of similar and similarly-placed ellipsoids. The kind of spheroid or ellipsoid to be employed will depend on what kinds of atoms are associated in the compound.

If we make the natural supposition that in all cases the different atoms have the same identical symmetrical disposition with respect to each of the different directions of *corresponding* crystal faces, the six types of symmetrical arrangement I have thus indicated are in harmony with various different symmetrical crystal forms.

Thus the colours in these two stacks (Figs. 6 and 7) have a perfectly hexagonal symmetry about a vertical axis, and therefore suggest a regular hexagonal prism terminated possibly by a regular hexagonal pyramid, the inclination of the pyramid faces to the prism faces depending on the kind of spheroid which has to be employed in place of spheres.

The arrangement of the colours in these two (Figs. 8 and 9) suggests a hexagonal prism terminated by trihedral summits, or by hexagonal pyramids with alternate faces similar.

The arrangement of the colours in these stacks (Figs. 10 and 11) suggests trimetric right prisms.

Neither of the six types is in harmony with the cubic system.

Now most of the compounds of the kind under consideration have their crystal forms in harmony with one or other of our six types.

Thus water, OH_2, crystallises in six-sided prisms or in rhombohedra.

Quartz, SiO_2, crystallises in six-sided prisms with pyramids.

Titanic oxide, TiO_2, in square prisms, in right rhombic prisms, and in acute octahedra.

Cuprous sulphide, Cu_2S, in six-sided prisms.

Lead chloride, $PbCl_2$, in six-sided needles.

Lead dioxide, PbO_2, in six-sided prisms.

And mercuric sulphide, which if—as already remarked—we estimate the atomic weight of mercury according to its gaseous volume, we shall write Hg_2S, crystallises in six-sided prisms.

About the only compound regarded as consisting of two kinds of atoms in the proportions 1 : 2 which crystallises in the cubic system is calcic fluoride (fluor-spar), and it is interesting to notice that a different atomic weight for calcium which would enable us to write calcic fluoride CaF, and thus add it to the list of compounds containing equal numbers of two kinds of atoms, would also enable us to trace a symmetrical system of arrangement for another compound of calcium, Iceland spar, in accordance with its crystal form: this I hope to show you presently.

In the case of one of the compounds I have just mentioned, quartz or rock crystal, the optical property possessed by this body of rotating the plane of polarisation of a polarised ray has been argued to indicate a spiral arrangement of the atoms, right-handed in some specimens, left-handed in others, this conclusion being supported by the well-known experiment of producing similar rotation by means of a combination of thin laminæ of mica arranged in the manner of winding stairs. In connection with this it is interesting to notice the beautiful spirals traced by the black and white balls in some of our six systems (Figs. 6, 7, 8, and 9).

From the rhombohedral symmetry of quartz I suppose that the two systems in which the smaller spirals occur (Figs. 8 and 9) are the types of the pair of systems according to which this substance is built up.

(To be continued).

ON THE ESTIMATION OF NITROUS COMPOUNDS IN VITRIOL.

By THOMAS BAYLEY.

In a paper on the "Applications of the Nitrometer," read by Mr. A. H. Allen before the Birmingham Section of the Society of Chemical Industry, and published in the *Journal* for March last, p. 178, it was stated that erroneous results might be obtained under certain circumstances in the assay of nitrous vitriol by the nitrometer.

Mr. Allen suggested that the solubility of nitric oxide in the acid liquid floating upon the mercury in the nitrometer-tube may, and does, lead to low analytical results, and he quoted some observations I had made at his request as evidence in favour of his contention.

In a communication subsequently published in the *Journal*, vol. iv., p. 447, Professor G. Lunge impugns the accuracy of my experiments, and therefore the validity of Mr. Allen's deduction from them. He also makes the assumption that the supposed inaccuracy was due to imperfect cooling of the gas before measurement.

One would have thought that before promulgating such an explanation as this and rejecting our general conclusions Professor Lunge would himself have repeated the experiments; but he appears to have preferred to work in an entirely different direction. He shook together pure sulphuric acid and pure nitric oxide in a nitrometer over mercury, and by these means demonstrated the practical insolubility of nitric oxide in sulphuric acid.

This result confirms my own experiments, and agrees with the general testimony of previous observers; but Professor Lunge appears to have overlooked the all-important fact that the liquid floating upon the mercury contained in a nitrometer after the shaking *is not pure sulphuric acid*, but a solution of mercurous nitrate in sulphuric acid.

Now the ordinary text-books and works of reference (*e.g.*, "Watts's Dictionary," "Gmelin's Handbook," &c.), credit the sub-salts of mercury and other metals with the power of dissolving nitric oxide gas.

I have repeatedly shaken nitrous vitriol, and also pure sulphuric acid mixed with nitric acid, in the nitrometer until the evolution of gas was complete, submitted the gas to ample cooling, re-shaken, and re-cooled several times, and then let the gas escape. The tube being now full to the tap with liquid, and free from gas, I have shaken it again to assure myself that no further disengagement of nitric oxide could be induced. I then have added water equal in volume to the acid liquid, and have invariably obtained a further liberation of gas, possessing the properties of nitric oxide.

Now Professor Lunge says:—"If Bayley's experiment were to be trusted, even the dilution recommended by Allen would not be sufficient, for strong oil of vitriol at 1·84 diluted with two-thirds its volume with water, yields acid of 1·62 sp. gr., at which strength Bayley asserts it to retain still 0·5 c.c. of gas."

But pure sulphuric acid (1·84) when saturated with NO will contain only a mere trace of that body, and hence cannot liberate any appreciable quantity on dilution. But it is a fact that on heating a solution of the nitric oxide in mercurous vitriol effervescence occurs with escape of the gas; and the dilution of vitriol with water generates

	Grms. of $NaNO_3$ per 100 c.c.		
1885.	With H_2O.	Without H_2O.	Difference.

heat. The dilution of the vitriol also causes a separation of dissolved mercurous salt, and if this salt be the agent causing solution the gas must be liberated when the salt is precipitated. The following experiments were made at my request by a gentleman who is accustomed to make a daily examination of the acid in certain vitriol chambers.

The following are my own experiments:—

Three grms. of pure sodium nitrite were dissolved in a few centimetres of water without loss, and the solution diluted with pure vitriol to 100 c.c. 3 c.c. of the solution liberated 7·8 c.c. of gas; and after addition of 3·5 c.c. of water, a further quantity of 0·5 c.c. of gas. Another sample of pure acid mixed with nitric acid; 2·0 c.c. liberated 7·5 c.c. in the first instance, and a further 0·45 c.c. on dilution with water. A second dilution frequently causes the liberation of further small quantities of gas. In order to confirm these results I adopted a different method of experimenting.

Nitric oxide was prepared by the action of nitric acid (sp. gr. 1·2) on copper ribbon, the gas being washed by means of potash solution, followed by strong sulphuric acid. The nitric oxide was passed through pure sulphuric acid contained in weighed Geissler-bulbs. A trace only of gas was dissolved, 14·678 grms. of pure acid retaining less than 0·001 grm. of NO.* Care was taken to employ carbonic acid gas so as to prevent the admission of air, and consequent oxidation of the nitric oxide.

This experiment having confirmed the insolubility of nitric oxide in strong sulphuric acid, the stream of NO was next passed through a solution of mercurous sulphate in some of the same sample of sulphuric acid. The mercurous solution was made in the nitrometer, and the acid was boiled and cooled before use. In this instance 14·678 grms. of acid gained 0·0098 grm. of NO.

A mercurous solution prepared by directly dissolving mercurous sulphate in strong sulphuric acid gave a similar result, the acid solution being in this case boiled and cooled before use.

THE METHODS OF ANALYSING FERTILISERS

ADOPTED BY THE

ASSOCIATION OF OFFICIAL AGRICULTURAL CHEMISTS OF THE UNITED STATES.

INCLUDING THE CHANGES MADE AT THE MEETING AT WASHINGTON, SEPTEMBER 1, 1885, WITH THE RECOMMENDATIONS REGARDING THE WORK OF THE SEASON OF 1885-'86.

THE following extracts from the proceedings of the meetings of the Association at Atlanta and at Washington are published by the North Carolina Experiment Station in a form for convenient reference in the laboratory.

CHARLES W. DABNEY, jun., *Secretary*.

Raleigh, N.C., October 24, 1885.

I. *Extract from Report of Committee on the Method of Determining Phosphoric Acid.*

(Washington Meeting, September 1, 1885.)

In conclusion your committee recommends that the methods of analysis adopted at our last meeting be amended as follows:—

"Before the 'Determination of Phosphoric Acid in Fertilisers' insert the following:—

Determination of Moisture in Fertilisers.

(1.) In potash salts, nitrate of soda, and sulphate of ammonia heat 1-5 grms. at 150° C. till the weight is constant, and reckon water from the loss.

(2.) In all other fertilisers heat 2 grms., or, if the sample is too coarse to secure uniform lots of 2 grms. each, 5 grms. for five hours at 100° C. in an air-bath."

Your committee also recommends that the following addition be made to the description of the Association's methods of determining citrate-insoluble phosphoric acid:—

"The method of extracting 'reverted' phosphoric acid was originally designed for and is applicable only to superphosphates, plain or nitrogenised, and was not intended to be applied to rock phosphates, natural guanos, or any other non-acidulated materials, to test their relative solubility or availability. In case, however, a determination of citrate-insoluble phosphoric acid is required in these non-acidulated goods, it is to be made by treating 2 grms. of the phosphatic material without previous washing with water, precisely in the way above described, except that in case the substance contains much animal matter (bone, fish, &c.), the residue, insoluble in ammonium citrate, is to be ignited with magnesium nitrate."

Your committee further recommends that in all other respects the method adopted at our last meeting (see after this report), for the determination of P_2O_5 in its three states *be rigorously followed during the coming year*. They *specially urge attention* to the following points:—

(1.) The solution of ammonium citrate to be strictly neutral and of the sp. gr. indicated.

(2.) Perfect solution of the phosphate in acid. After boiling with acid, diluting, and decanting, it is well to boil the insoluble residue again with strong acid.

(3.) The magnesia mixture to be added not more rapidly than indicated (one drop per second).—Peitsch, Rohn, and Wagner, *Fres. Zeitschr. f. Analyt. Chem.*, xix., 448.

Since the ignition with $Mg(NO_3)_2$ requires some time and an additional transfer of the material from one vessel to another, which always involves the possibility of mechanical loss, experiments are desirable to determine whether organic matter can be destroyed or made harmless by oxidation in the wet way, by fuming nitric acid or other reagents, in the flask in which the subsequent solution of the phosphate is to be made.

It is also desirable to know to what extent silica passes into solution when phosphates of various kinds are digested in strong acid. A single experiment on "SoCa" gave the writer:—

Total sand and silica	3·92 p.c.
Brought into solution by boiling in strong HCl	0·02 ,,
Brought into soltn. by ignition with $Mg(NO_3)_2$ and adding strong HCl	0·05 ,,

It is also desirable to know just what effect silica in solution has on the determination of P_2O_5 by the molybdate method. The testimony on this point is conflicting. *See* Bertrand, *Jahresb. Ag. Chem.*, xxvi., 318; Lindo, CHEMICAL NEWS, xlix., 1884, 247, *et seq.*; *Bied. Centralbl. Ag. Chem.*, 1884, 642; Atkinson, *Fres. Zeit. f. Analyt. Chem.*, xviii., 447; Jenkins, *Jour. f. Prakt. Chem.*, xiii., 237.

Your committee also express the belief that an annual distribution of samples and comparison of results will be of great use in securing accuracy and uniformity among analysts, and urge on the members of the Association the desirability of promptly analysing and reporting results on samples which they receive.

All of which is respectfully submitted,

E. H. JENKINS,
H. C. WHITE,
W. C. STUBBS.

Washington, D.C., Sept. 1, 1885.

Determination of Phosphoric Acid in Fertilisers.

(Method adopted at Atlanta, 1884. Still in force.)

1. The sample should be well intermixed and properly prepared, so that separate portions shall accurately repre-

* The acid used for this experiment, which was commercially pure, and had probably not been subjected to distillation, contained small traces of copper and iron. The presence of these metals no doubt accounted for the change of tint which the passage of the gas occasioned. Very few samples of acid when submitted to this test remain colourless.

sent the substance under examination, without loss or gain of moisture.

2. *Water-soluble Phosphoric Acid.*—Bring 2 grms. on a filter; add a little water; let it run out before adding more water; and repeat this treatment cautiously until no phosphate is likely to precipitate in the filter. (The washings may show turbidity after passing the filter.) When the substance is nearly washed in this manner, it is transferred to a mortar and rubbed with a rubber-tipped pestle to a homogeneous paste (but not further pulverised), then returned to the filter, and washed with water until the washings no longer react acid with delicate test-paper. Mix the washings. Take an aliquot (usually corresponding to one-third or one-half of a grm. of the substance), and determine phosphoric acid as under total phosphoric acid.

3. *Citrate-insoluble Phosphoric Acid.*—Wash the residue of the treatment with water into a 150 c.c. flask with 100 c.c. of strictly neutral ammonium citrate solution of 1·09 density; shred and add the filter-paper; cork the flask securely; place in a water-bath with constant temperature of 65° C., and digest for thirty minutes with frequent shaking. Filter the warm solution quickly, and wash with water of ordinary temperature.*

Transfer the filter and its contents to a porcelain capsule. Ignite until the organic matter is destroyed; treat with 10 to 15 c.c. of fuming hydrochloric acid; digest over a low flame until the phosphate is dissolved; dilute to 200 c.c.; mix; pass through a dry filter; take an aliquot, and determine phosphoric acid as under total.

4. *Total Phosphoric Acid.*—Weigh 2 grms. into a capsule, add and mix intimately with 4 to 7 c.c. of a nearly saturated solution of magnesium nitrate, dry, ignite gently, if necessary, moisten the residue with nitric acid, and ignite again to destroy all organic matter; add to the residue 15 to 20 c.c. of fuming hydrochloric acid; digest at a gentle heat until all phosphates are dissolved; dilute to 200 c.c.; mix; pass through a dry filter; take 50 c.c. of filtrate; neutralise with ammonia; add about 15 grms. dry ammonium nitrate; and to the hot solution, for every decigrm. of P_2O_5 that is present, 50 c.c. of molybdic solution. Digest at about 65° C. for one hour; filter and wash with ammonium nitrate solution. (Test the filtrate by renewed digestion and addition of more molybdic solution.)

Dissolve the precipitate on the filter with ammonia and hot water, and wash into a beaker to a bulk of not more than 100 c.c. Nearly neutralise with hydrochloric acid; cool, and add magnesia mixture from a burette, slowly (one drop per second), stirring vigorously. After fifteen minutes add 30 c.c. of ammonia solution of density 0·96. Let stand several hours. (Two hours is usually enough.) Filter; wash with dilute ammonia; ignite intensely for ten minutes, and weigh.

5. *Citrate-Soluble Phosphoric Acid.*—The sum of the water-soluble, and citrate-insoluble, subtracted from the total gives the citrate-soluble.

Preparation of Reagents.

1. *To prepare Ammonium Nitrate Solution.*—Mix 370 grms. of commercial citric acid with 1500 c.c. of water; nearly neutralise with crushed commercial carbonate of ammonia, 410 grms.; heat to expel the carbonic acid; cool; add ammonia until exactly neutral (testing for excess both of acid and alkali by aid of delicate red and blue litmus-papers), and bring to volume of 2 litres. Dilute further until the density is 1·09, as tested by the balance or *accurate* specific gravity spindle.

2. *To prepare Solution of Magnesium Nitrate.*—Dissolve 320 grms. of "calcined magnesia" in nitric acid, avoiding excess of the latter; then add a little "calcined magnesia" in excess, and boil; filter from the excess of magnesia, ferric oxide, &c., and bring to volume of 2 litres.

3. *To prepare Molybdic Solution.*—Dissolve 100 grms. of molybdic acid in 400 grms. or 417 c.c. of ammonia of sp. gr. 0·96, and pour the solution thus obtained into 1500 grms. or 1250 c.c. of nitric acid of sp. gr. 1·20. Keep the mixture in a warm place for several days, or until a portion heated to 40° C. deposits no yellow precipitate of ammonium phospho-molybdate. Decant the solution from any sediment, and preserve in glass-stoppered vessels.

4. *To prepare Ammonium Nitrate Solution.*—Dissolve 200 grms. of commercial ammonium nitrate in water, and bring to a volume of 2 litres.

5. *To prepare Magnesia Mixture.*—Dissolve 22 grms. of recently ignited "calcined magnesia" in dilute hydrochloric acid, avoiding excess of the latter. Add a little "calcined magnesia" in excess, and boil a few minutes to precipitate iron, alumina, and phosphoric acid; filter; add 280 grms. of ammonium chloride, 700 c.c. of ammonia of sp. gr. 0·96, and water enough to make the volume of 2 litres. Instead of the solution of 22 grms. of "calcined magnesia," 110 grms. of crystallised magnesium chloride ($MgCl_2.6H_2O$) may be used.

6. *Dilute Ammonia for Washing.*—One volume ammonia of sp. gr. 0·96 mixed with three volumes of water, or, *usually*, 1 volume of concentrated ammonia with 6 volumes of water.

2. *Method for estimating Potash—Extract from the Report of the Committee on Potash.*

(Washington Meeting, September 1, 1885.)

In case the potash is contained in organic compounds, like tobacco-stems, cotton-seed, hulls, &c., it is to be saturated with strong sulphuric acid and ignited in a muffle to destroy organic matter. Pulverise the fertiliser (200 or 300 grms.) in a mortar. Take 10 grms., boil for ten minutes with 200 c.c. water, and, after cooling and without filtering, make up to 1000 c.c., and filter through a dry paper. If the sample have 10 to 15 per cent K_2O (kainite) take 25 c.c. of the filtrate; if from 2 to 3 per cent K_2O (ordinary potash fertilisers), take 100 c.c. of the filtrate. In each case make the volume up to 150 c.c., heat to 100° C., and add drop by drop with constant stirring a slight excess of barium chloride. Without filtering, in the same manner add barium hydrate in slight excess. Filter and wash until the precipitate is free of chlorides. Add to filtrate 1 c.c. strong ammonium hydrate, and then drop by drop a saturated solution of ammonium carbonate until the excess of barium is precipitated. Add now, in fine powder, 5 grms. pure oxalic acid or 0·75 grm. ammonium oxalate. Filter, wash the precipitate free of chlorides, evaporate filtrate to dryness in a porcelain dish, and, holding dish with crucible tongs, ignite carefully over the free flame below red-heat until all volatile matter is driven off.

The residue is now digested with hot water, filtered through a 5 c.m. filter, and washed with successive portions of 2 c.c. hot water until the filtrate amounts to 30 c.c. To this filtrate, after adding 2 drops of strong hydrochloric acid, is added in a porcelain dish 10 c.c. of a solution of 10 grms. of platinic chloride in 100 c.c. of water. The mixture is now evaporated on the water-bath to a thick syrup, treated with 85 per cent alcohol, well rubbed with the stirring rod, washed with 85 per cent alcohol by decantation, collected on a Gooch crucible, washed with 85 c.c. alcohol, afterwards with 5 c.c. ether, dried for thirty minutes at 100° C., and weighed. It is not necessary to check the results by washing out the precipitate and re-weighing the crucible, or by reducing its weight after washing out the potassium chloride. We recommend the continuance of the use of the factor 30·56 for converting K_2PtCl_6 to KCl, and 19·308 for converting to K_2O. We further recommend that the Committee on Potash, which may be appointed for the coming year, distribute at an early date samples of fertilisers to members

* This filtration should not exceed fifteen to twenty minutes in duration, and in difficult cases is best effected by use of a plaited filter of very porous paper or by help of a filter-pump of *moderate* power.

of the Association and others interested, with such recommendations as may seem best suited to secure a thorough trial of this and all new methods which may appear to promise success.

Respectfully submitted,

H. W. Wiley,
W. J. Gascoyne.
Clifford Richardson.

3. *Nitrogen Determination.*

No method for determining nitrogen in fertilisers was adopted by the Association.

ELECTROLYTIC SEPARATION OF ZINC AND CADMIUM.

By S. Eliasberg.

The separation of these metals by gravimetric methods does not, as is well known, rank among the easier tasks of analytical chemistry. An electrolytic method was proposed in 1880 by A. Iver (*Bull. Soc. Chim. de Paris*), and requires consideration. He mixes the acetic or sulphuric solutions of the metals with 2 to 3 grms. sodium acetate, adds a few drops of acetic acid, applies heat, and electrolyses by means of two Daniell elements. The author has examined this method at the request of Prof. Classen, and has found that the heat must be kept up during the entire duration of the electrolysis, as the cadmium is not completely deposited from a cold solution. The statement of the strength of the current as that of two Daniell elements is not sufficiently precise, as an equal number of elements of the same kind do not always give currents of the same strength according to the strength of the acids, &c.

It has frequently happened that two Bunsen elements gave off from 10 to 20 c.c. detonating gas per minute, according as they were more or less carefully prepared. This point requires particular prominence, since the author has not succeeded in getting good results with two Daniell elements which gave off 0·2 c.c. detonating gas per minute: the current was too feeble to throw down all the cadmium.

The strength of a current had to be ascertained at which all the cadmium was deposited, but not all the zinc. The most suitable current was found to be one giving off 0·5 to 0·6 c.c. detonating gas per minute. It was obtained by means of two Bunsen elements with the introduction of a resistance.

As to the concentration of the solution nothing was laid down by Iver. According to the author's experience the capsule must not contain more than 90 c.c. When this is the case good results are generally obtained in six hours (not three to four, as stated by Iver). Sometimes, however, zinc oxide separates out in the capsule at the margin of the liquid, when the analysis is lost.

In the separation of these metals the author uses soluble double oxalates. He proceeds as follows:—

The metallic oxides are dissolved in hydrochloric acid, evaporated to dryness, mixed with 8 to 10 grms. potassium oxalate and 2 to 3 grms. ammonium oxalate, diluted to about 100 c.c., heated almost to a boil, and submitted to electrolysis, keeping up the temperature but avoiding ebullition. The liquid does not evaporate away, as the steam for the most part condenses on the glass cover and drops back. If a considerable loss by evaporation is perceived water may be added.

The strength of the current was 0·01 to 0·015 ampère, the evolution of detonating gas being 0·1 to 0·15 c.c. per minute. In six to seven hours the separation is complete. The cadmium separates out chiefly with a smooth surface, but partly in a crystalline form. If more than 0·15 grm. of metal are taken a longer time is requisite.—*Zeitschrift für Analytische Chemie.*

NOTICES OF BOOKS.

Physico-Chemical Constants: Melting- and Boiling-point Tables. By Thomas Carnelley, D.Sc (London), B.Sc. (Vict.), F.C.S., Professor of Chemistry in University College, Dundee. London: Harrison and Sons.

No kind of physical or chemical research is at once so useful to the scientific world, so laborious, and so immediately unremunerative to the experimentalist, as the determination of constants. Whilst requiring skill in manipulation, acuteness in detecting and eliminating sources of error, and above all an unlimited fund of patience, the results meet with little acknowledgment. The work, of which the first volume lies before us, is a gigantic undertaking. The author's original object was to trace the connection—if any—between the chemical composition and the melting- and boiling-points of inorganic bodies. For this purpose many determinations became necessary, and new processes had in many cases to be elaborated. Gradually the investigation was also extended to organic substances—a task which, as the author informs us, and as we can well believe, has taken eight years of almost continuous labour.

The present volume contains nearly 19,000 separate determinations of melting- and boiling-points, and the forthcoming volume will bring the number up to 50,000.

Dr. Carnelley's objects have been to prepare as complete a list as possible of all known melting- and boiling-points, indicating, in the frequent case of discrepant authorities, which determination is the most exact; to state, as fully as possible, the constitution of each substance; to adopt a convenient system of arrangement; to give the authority along with reference to original memoirs; and, to meet the requirements of those who have not ready access to large libraries, references as far as possible to "Watts's Dictionary" and to the *Journal of the Chemical Society*.

The discrepancies in certain cases are remarkable, and are doubtless due either to the selection of impure specimens or to the use of imperfect methods. As an instance we may mention boron. According to Mott this substance fuses at 300°, whilst Roscoe and Schorlemmer say "above a white heat," Odling "at an intense heat," and Dépretz "in the electric arc." Again, uranium—according to Mott—fuzes at 207°, whilst Roscoe finds it "fusible only before oxyhydrogen blowpipe."

Concerning gallium, also, authorities differ. Lecoq de Boisbaudran gives its fusion-point as 30·15°, whilst Pictet places it as low as −20°, which Dr. Carnelley queries. In such cases the author italicises the value which appears to be the most accurate.

The volume is furnished with a table of contents, with explanatory notes, a list of abbreviations, and a catalogue of references. Concerning the high value of this work, both to the theoretical investigator and to the technical chemist, no two opinions can prevail.

CORRESPONDENCE.

THE INSTITUTE OF CHEMISTRY.

To the Editor of the Chemical News.

Sir,—I cordially endorse the views expressed by your correspondent signing himself "A Practising Fellow of the Institute," printed on page 318.

It is quite time that the members of the Institute generally should understand to what the Council have committed them, so that they may either give the action of the latter a deliberate endorsement or may elect those who will more accurately represent their views.

The Council have decided that future Members and

Associates of the Institute must have studied for three years in one of the score or so of "Colleges" the curriculum of which is regarded as satisfactory. This decision was arrived at deliberately, although it was pointed out during the discussion that such a regulation practically prohibited members of the Institute who were not connected with those colleges from taking apprentices with a view to their subsequently joining the Institute. Such a decision, amounting practically to a boycotting of a considerable number of members of the Institute, could only be justified if it could be shown that it was impossible to acquire an adequate knowledge of the profession in a private laboratory, which is far from being the fact.

The Council attach importance to three main subjects: mathematics, physics, and chemistry. Of these, surely no one will contend that mathematics cannot be adequately studied outside the walls of a "College," and of all subjects it is the one which most readily admits of a satisfactory examination-test. Physics is less easily studied in private; but as long as a careful examination shows the candidate's knowledge to be sufficient, it is surely a matter of indifference how he came by his information. As to chemistry, all will admit the importance of attending a course of properly illustrated lectures; but a knowledge of lecture-table chemistry will not make a man a chemist, any more than skill in laboratory manipulation alone will suffice for that purpose. Working Fellows of the Institute have a painful knowledge of the awful rubbish frequently turned out by some of the "Colleges," the curriculum of which is accepted by the Council as evidence of adequate training, and it is an open secret that such courses have often to be succeeded by a study of the elements of analytical chemistry in the laboratory of a practising chemist.

By all means make the examinations as rigid and searching as possible, so as to ensure true competency on the part of those candidates who pass. On the other hand, while requiring a sound knowledge of chemistry, &c., generally it would only be fair to allow a candidate the option of being examined more especially in some particular branch, such as chemical engineering, metallurgical chemistry, sanitary chemistry, organic research, &c. But it is ridiculous to depute any one man to act as examiner in chemistry, as, with all respect to those gentlemen who have hitherto acted in that capacity, no one man is likely to have such a thorough knowledge of chemistry as to qualify him to form a judicial opinion on the knowledge of a candidate. The questions hitherto set to students have, I believe, never been published, as they certainly should have been.

The truth is, that the Institute is dominated by the school-master interest. A chemist who exercises the functions of a science-teacher assumes a superiority over those of greater experience and all-round knowledge of the profession who happen to be engaged in private practice, and he is very ready to impress on the public and sucking students his exalted position as Professor Dash as compared with those of Mr. Blank.

Whether devised with such an intention or not, the practical effect of the existing regulation is to boycott Mr. Blank and to swell the fees of Professor Dash.

I am one who has been foolish enough to pay his subscription to the Institute for a number of years, in the hope, long deferred, that some good would come of it at last; and now it promises to boycott me and to admit a number of chemists who, for reasons doubtless satisfactory to themselves, have hitherto stood aloof. I am sorry I did not do the same, and am prepared to resign now if things are not altered.

It is quite clear that, as at present constituted, the Institute will not include many whose knowledge and attainments fully qualify them for membership, and therefore it cannot exercise the functions to which it aspires. Hence, if it cannot be altered to a reasonable working form, it will be better for those who think with me to leave it at once in a body than to pay their subscriptions for nothing for a certain term of years. and then have the affair wound up, or find they have created a Frankenstein. I cannot afford to offend the powers that be, but if I knew I had adequate support I would do my utmost to remedy the present condition of affairs, and have therefore requested the publisher to forward any letters addressed to me at the office of this Journal. Any communications I may receive will be regarded as confidential, and shall be duly acknowledged through the post.—I am, &c.,

A. Blank.

THE INSTITUTE OF CHEMISTRY.

To the Editor of the Chemical News.

Sir,—I do not agree with your correspondent "V." that "between 1877—80 the doors of the Institute were opened sufficiently wide and long" to admit all who might justly claim to be enrolled as members, and I think the proposal to admit for a time on "evidence of fitness" is a step in the right direction in the interests of the Institute itself.

The panic created in the minds of certain members by the proposal to suspend examinations for a time is remarkable, when we remember that somewhere about 90 per cent of the present members were enrolled without any examination.

If it was possible in the past to form a satisfactory nucleus without examinations, it is difficult to understand how a renewal of the practice should be so reprehensible now. There are many competent chemists who would willingly join the Institute if permitted to offer evidence of their ability, and who, as busy specialists, could not now without preparation pass the practical examination in general analytical chemistry required by the Institute.

While I do not think that the qualifications required by the Institute are at all too high for candidates who have had an opportunity of preparing themselves, I do think that the requirements are too exacting to suit chemists who have earned their bread by the exercise of their profession before the Institute of Chemistry had any existence; and to these some consideration should be extended.

I would venture to suggest that the degree of Associate should be made a permanent one, instead of being probationary as at present, to those admitted on "evidence of fitness," with permission to take the degree of Fellow on passing the necessary examinations, or on publishing an original research of sufficient merit.—I am, &c.,

A Manure Works' Chemist.

ANALYSIS OF A NORWEGIAN ICEBERG.

To the Editor of the Chemical News.

Sir,—The following analysis is being largely circulated as an advertisement in the West End; but seeing that it contains such interesting scientific matter I am sure you will think it worth recording in your columns, more especially as the analysts have been the first to discover *magnesium* as a natural product, and that, strangely to say, in a *block of ice*; the *alumina*, I presume, is also held in suspension.

"The following is an analysis of a *block of ice* as supplied by us;—

Chloride of potass	..	One grain and a quarter.
Magnesium	..	Half a grain.
Sulphate of lime	..	One quarter of a grain.
Alumina	..	One quarter of a grain.
Organic matter ..	..	None whatever.

Signed —— ——."

Would the above discovery be considered as sufficient "evidence of fitness" by the Council of the Institute of Chemistry for admittance to that august Corporation?—I am, &c.,

Jack of All Trades, Master of None.

CHEMICAL NOTICES FROM FOREIGN SOURCES.

NOTE.—All degrees of temperature are Centigrade unless otherwise expressed.

Comptes Rendus Hebdomadaires des Séances, de l' Academie des Sciences. Vol. ci., No. 24, December 14, 1885.

Method of Analysis applicable to Mixtures of Hydrocarbons of the Aromatic Series.—C. Friedel and J. M. Crafts.—This memoir will be inserted in full.

Relations between the Absorption of Light and the Emission of Phosphorescence in the Compounds of Uranium.—Henri Becquerel.—The uranium compounds may be divided into two classes corresponding to distinct optical properties. The former are for the most part phosphorescent. On analysing with the spectroscope the light which they emit we perceive in general a discontinuous spectrum formed of seven or eight bands or groups of bands, regularly distributed between the rays C and F, the positions and apppearances of which vary with the nature of the compounds. These same substances present an absorption spectrum formed of bands, the position, grouping, and aspect of which represent in the spectrum the continuation of the regular series of the bands which they emit on phosphorescence. The wave-lengths of all the bands, whether of the phosphorescence spectrum or of the absorption spectrum of one and the same compound, are connected by a law which may be expressed as follows:—the difference of the numbers of luminous vibrations during the same time is sensibly constant in passing from one group to the next, and the value of this difference varies little for the different compounds of uranyl. Each absorption band corresponds to a totality of radiations which excite phosphorescence. On exciting various compounds exclusively by the radiations corresponding to each of the absorption-bands the author finds that in each case the phosphorescence spectrum presents the seven or eight bands less refrangible than the exciting region in question. Thus the radiations absorbed by the uranyl compounds, satisfying a common law, all excite in these bodies the same luminous vibratory movements of different periods, and which appear to be the lower harmonics of the exciting radiations. The uranous compounds, which do not present any appreciable phosphorescence, give a very remarkable discontinuous absorption-spectrum, from F to very far in the ultra-red. Strong absorption bands in the red and ultra-red region are characteristic of the uranous compounds, as well as a broad band in the green ($\lambda = 549$) very near in position to that of the most intense group of lines of the emission spectrum of incandescent uranium. The absorption-bands of the uranous compounds follow with a remarkable regularity the law of distribution of the phosphorescent emission-bands of the uranic compounds, but without having the same relative intensity.

Band-Spectrum of Nitrogen; its Origin.—H. Deslandres.—Of the three groups of bands recognised the author traces the third to an oxide of nitrogen, probably hyponitric acid. The second group is probably due to ammonia, whilst the first may be ascribed either to nitrogen alone or to another compound of nitrogen and hydrogen.

The Hydrates of Arsenic Acid.—A. Joly.—A thermochemical study of the hydrates of arsenic acid, of which the author distinguishes three, containing respectively 2, 3, and 4 mols. of water.

Researches on the Formation of Deposits of Sodium Nitrate.—A. Muntz.—These deposits owe their origin to the nitrogen of organic matters, oxidised under the influence of the ferment of nitrification. Sea-water, or, perhaps, the water of salt-marshes, has been in contact with these substances during the course of nitrification. Sodium nitrate is produced by the double decomposition of the calcium nitrate and of sodium chloride. The nitre has not been formed in the districts which it now occupies, but has been concentrated there after leaving its place of origin.

New Researches on Proteic Substances.—P. Schützenberger.—As the formula of albumen the author adopts $C_{29}H_{48}N_8O_{10}$.

Preparation of Benzoyl-cyanacetic Ether and of Cyan-acetophenone.—M. Haller.—The former body appears as hard, prismatic crystals, soluble in alcohol, ether, potassa, and sodium carbonate. They melt at 37·5°. The alcoholic solutions have a distinctly acid reaction and give with ferric salts a fine red colouration.

Increase of Nitrogen in a Soil kept in Grass.—P. P. Dehérain.—The author thinks, with Lawes and Gilbert, that the nitrates of subsoil waters may rank among the sources of combined nitrogen. In a soil like that of a meadow, never disturbed, the losses by slow combustion are smaller than in an arable soil.

Chemical Study of Matter dredged up by the Travailleur and the Talisman.—M. Dieulefait.—Copper and zinc were both universally detected in deposits obtained at great depths, and in regions of the ocean widely remote from each other.

NOTES AND QUERIES.

*** Our Notes and Queries column was opened for the purpose of giving and obtaining information likely to be of use to our readers generally. We cannot undertake to let this column be the means of transmitting merely private information, or such trade notices as should legitimately come in the advertising columns.

Algin.—(Reply to E. B.)—If this correspondent will send his name and address samples of algin shall be forwarded to him.—E. C. C. STANFORD, Glenwood, Dalmuir, N. B.

Electrical Battery.—Can any of your correspondents inform me where I may obtain particulars of a form of electrical battery, in which the exciting liquid is a hot supersaturated solution of either nitrate of potash or soda, one of the elements being carbon made red-hot before being plunged into the nitrate; the other I do not know.—G. S. PACKER.

MEETINGS FOR THE WEEK.

MONDAY, 4th.—London Institution, 5.
—— Medical, 8.30.
—— Society of Chemical Industry, 8. "Enrichment of Coal-gas by Hydrocarbons," by Mr. G. E. Davis. "Notes on Russian Turpentine," by Mr. C. T. Kingzett.
TUESDAY, 5th.—Royal Institution, 3. "The Story of a Meteorite," by Prof. Dewar.
—— Pathological, 8.30. (Anniversary).
THURSDAY, 7th.—Royal Institution, 3. "The Story of a Meteorite," by Prof. Dewar.
—— London Institution, 7.
—— Royal, 4.30.
—— Royal Society Club, 6.30.
FRIDAY, 8th.—Quekett Club, 8.
—— Astronomical, 8.
SATURDAY, 9th.—Royal Institution, 3, "The Story of a Meteorite," by Prof. Dewar.

TO CORRESPONDENTS.

Oxonian.—The attack is too personal to be inserted.

Silicates of Soda and Potash in the state of Soluble Glass, or in CONCENTRATED SOLUTION of first quality, suited for the Manufacture of Soap and other purposes, supplied on best terms by W. GOSSAGE and Sons Soap Works, Widnes, Lancashire

London Agents, COSTE and Co., 19 and 20, Water Lane, Tower Street, E.C., who hold stock ready for delivery.

PATENTS, DESIGNS, & TRADE MARKS ACT, 1883.

In the matter of Letters Patent granted to JOHN FORDRED, of Tottenham, in the county of Middlesex, for "Improvements in the preparation of grain or cereals for use in brewing, distilling, and vinegar making," dated 8th November, 1881, No. 4891.

NOTICE IS HEREBY GIVEN that the said John Fordred has applied for leave to amend the specification numbered as above.

A copy of the Specification as proposed to be amended can be inspected at the Patent Office, and full particulars of the proposed amendment were published in the Official Journal of the Patent Office, issued on the 18th December, 1885.

Any person intending to oppose the said application must leave particulars in writing of his objections thereto at the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C., within one calendar month from the date hereof.

Dated this 18th day of December, 1885.

(Signed) H. READER LACK,
Comptroller General.

COMPLETE SET (unbound and uncut) of

THE CHEMICAL GAZETTE,

A Journal of Practical Chemistry.

17 Volumes; from November, 1842, to December, 1859.

Address, "Publisher," CHEMICAL NEWS Office, Boy Court, Ludgate Hill, London, E.C.

MESSRS. PAUL DALLDORF and CO., in GOTHENBURG, want to Represent, for Scandinavia, first-rate Manufacturers for the
SALE OF CHEMICALS FOR DYERS, MATCH, PAPER, AND GLASS MANUFACTURERS.

FINEST REFERENCES CAN BE GIVEN.

CORRESPONDENCE IN ENGLISH AND GERMAN.

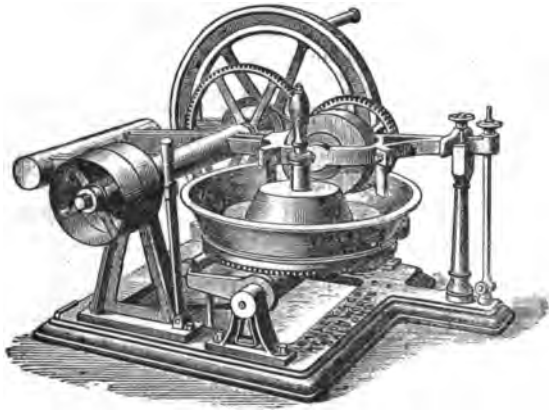
(CARR'S PATENT),

BAILEY'S LABORATORY MILL

With Wedgwood-ware Pan and Runner. For Hand or Power.

Suitable for Levigating Chemicals, Drugs, Powders, Minerals, Paints, and for General Laboratory Purposes.

Approved by some of the most eminent Chemists, and awarded the Silver Prize Medals of the Manchester and Liverpool, and the Middleton Agricultural Shows.



The chief feature in this machine is, that although it can be turned with ease, it has immense frictional power for levigating purposes. This is caused by the runner being driven at a much greater speed than the bowl. The surfaces are clean, smooth, and durable.

Dia. of Bowl, 18 ins. Price, £11 nett cash, delivered in Manchester. This Levigator is also suitable for triturating and mixing Medicines, Vegetable Powders, Ointments, Paints, Sugar, Salt, Spices, Herbs, Mineral Ores, &c., and will grind the coarsest emery into a nearly impalpable powder in a few seconds. The Pan can be tilted for emptying.

W. H. BAILEY & Co., Albion Works, Salford, Manchester.

SCIENCE DEPOT
HIRE & EXCHANGE.

ESTABLISHED 1862.

UNIVERSAL TRADE AND AMATEUR SUPPLY. Lecture and Laboratory requisites—Electricity, Sound, Light, Heat, Air, Water, Geology, Engineering, Photography, &c. Wholesale and Export. CHEMICAL APPARATUS, Chemicals, Pumps, Balances, Stills, Furnaces, Blowpipes, Chemical Cabinets, Rare Metals, Minerals, Models of Crystals. Graduated Glass, Porcelain, Copper, and Platinum Vessels of all kinds, New and Second-hand. Catalogue 2d.—Professor CAPLATZI, CHENIES STREET, TOTTENHAM COURT ROAD, and at the SCIENCE CO-OPERATIVE SUPPLY, 22, Charlotte Street, Fitzroy Square.

ESTABLISHED 1798.

VOL. LIII. No. 1363.

ON THE LIMITED HYDRATION OF AMMONIUM CARBAMATE.*

By H. J. H. BENTON, M.A., F.C.S., F.I.C.,
Demonstrator of Chemistry in the University of Cambridge.

IT occurred to me that a study of the action of water on ammonium carbamate, with reference to the influence of time, mass, and temperature, would be of interest as tending to throw light upon the laws which govern a chemical action of the simplest type in the liquid state—the action consisting of the direct union of two simpler molecules to form one more complex—

$$CO(NH_2)(ONH_4)+OH_2=CO(ONH_4)_2.$$

There are but few such actions which can be investigated, where all the substances are in the liquid state and all extraneous matter absent.

In a paper read before the Chemical Society in 1879,† I showed that ammonium carbamate when acted upon by sodium hypochlorite in presence of sodium hydroxide, yields one-half of its nitrogen in the free state, the other half remaining in the form of sodium carbamate—

$$2CO(NH_2)(ONH_4)+3NaClO+2NaOH=$$
$$=2CO(NH_2)(ONa)+3NaCl+5OH_2+N_2.$$

Sodium hypobromite at once decomposes sodium carbamate, evolving its nitrogen in the free state—

$$2CO(NH_2)(ONa)+3NaBrO+2NaOH=$$
$$=2CO(ONa)_2+3NaBr+3H_2O+N_2.$$

This, in fact, may be claimed as a specific reaction for carbamates—no other substance yet investigated will yield nitrogen when treated with a hypobromite *after* the completed action of a hypochlorite. Urea evolves but half its nitrogen with a hypochlorite, in presence of caustic alkali, but the other half remains as a cyanate, which is not acted upon by a hypobromite.‡

Based upon this reaction, then, we have a direct and simple method of determining the amount of carbamate existing in a solution at any given time.

Since, under the action of a hypochlorite, ammonium carbamate yields one-half of its nitrogen (*i.e.*, that present as ammonium), it is evident that any excess over and above this half which is evolved from its solution, is a measure of the water which has been assimilated, converting the carbamate into carbonate.

For the sake of convenience we may express the hydration which occurs in terms of the ratio of the number of molecules of water assimilated to that of the molecules of ammonium carbamate taken. Let V = the total volume of nitrogen contained in the ammonium carbamate taken, and V_1 = that evolved by the action of a hypochlorite on its solution. Then the above ratio evidently = $\frac{2V_1-V}{V}$ (since one atom of nitrogen evolved in excess of the half total corresponds to one molecule of water assimilated, and two atoms of nitrogen originally present represent one molecule of ammonium carbamate taken).

The ammonium carbamate used in these experiments was prepared by the direct union of carefully dried ammonia and carbon dioxide. The apparatus employed in the estimation of the evolved nitrogen was similar to that described in a former paper on the action of "Hypochlorites in Urea."‡

* A Paper read before the Royal Society, December 10, 1885.
† *Chem. Soc. Journ.*, 35, 12.
‡ *Ibid.*, July, 1878.

Experiments were undertaken with a view of investigating to what extent the action is influenced by (1) time, (2) mass, (3) temperature and (4) to study the reverse action, namely, the dehydration of normal ammonium carbonate into ammonium carbamate.

I. *Influence of Time.*

Weighed quantities of ammonium carbamate were dissolved in water and the solutions made up to a definite volume. Measured portions were then withdrawn and examined at stated intervals by treatment with sodium hypochlorite and sodium hydroxide; care being taken to employ approximately the same quantities of reagents for each experiment of the series. The times were reckoned from the moments of complete solution of the salt.

6·2873 grms. ammonium carbamate dissolved in water—the solution made up to 100 c.c. and 5 c.c. (corresponding to 0·31437 grm. of carbamate) taken for each experiment. Theory for total nitrogen = 90·20 c.c.

Minutes.	Intervals.	C.c. of Nitrogen (corrected).	Hydration.
5	1	54·16	0·2008
10	2	56·71	0·2575
20	4	60·37	0·3386
40	8	66·04	0·4644
60	12	68·60	0·5211
100	20	71·44	0·5842
120	24	72·08	0·5983
160	32	72·72	0·6125

After a further interval of about twenty-four hours, 72·28 c.c. of nitrogen were evolved. Similar experiments were made with a weaker solution, namely, one containing 4·8781 grms. of ammonium carbamate in 250 c.c.; 10 c.c. were taken for each determination, corresponding to 0·1951 grm. of carbamate, and to a total of 55·98 c.c. of nitrogen.

Minutes.	Intervals.	C.c. of Nitrogen (corrected).	Hydration.
5	1	35·09	0·2536
10	2	38·72	0·3833
20	4	40·91	0·4615
40	8	43·20	0·5434
60	12	45·70	0·6327
120	24	47·47	0·6960
220	44	47·57	0·6995

After about twenty-four hours 47·96 c.c. of nitrogen were obtained.

It is evident from these results that the action, which proceeds rapidly at first, becomes progressively slower, and finally reaches a limit short of complete hydration.

The time required to reach a determinate state of hydration is evidently greater for a strong solution than a weak one, *i.e.*, decreases as the relative number of water molecules increases.

II. *Influence of Mass.*

8·3272 grms. of ammonium carbamate were dissolved in water and the solution made up to 100 c.c. (Solution A.)

25 c.c. of solution A were made up to 50 c.c. (Solution B.)

25 c.c. of solution A were made up to 250 c.c. (Solution C.)

The relative strengths were therefore A : B : C :: 1 : ½ : $\frac{1}{10}$.

The solutions were set aside for four days in carefully stoppered flasks and under similar conditions. Volumes of each solution which corresponded to equal masses of ammonium carbamate were then withdrawn—namely, 5 c.c. of A, 10 c.c. of B, and 50 c.c. of C, representing 0·41636 grm. of carbamate—and examined by the hypochlorite method in the usual way.

5	c.c. of	A	gave	95·73 c.c. N (corr.).
10	,,	B	,,	99·99 ,,
50	,,	C	,,	110·60 ,,

In order to be certain that the equilibrium state had been arrived at, the same solutions were again examined after a further interval of two days, when

5 c.c. of A gave 95·35 c.c. N (corr.).
10 „ B „ 99·96 „
50 „ C „ 110·83 „

showing that the limits had been reached in the former experiments. These numbers correspond to the hydrations—

A .. .. 0·5963
B .. .. 0·6735
C .. .. 0·8550

In order further to confirm these results, the residues from the last experiments, after the completed action of the hypochlorite, were treated with sodium hypobromite in order to estimate the nitrogen remaining as carbamate.

Residue from A gave 22·02 c.c. N (corr.).
„ „ B „ 17·50 „
„ „ C „ 8·01 „

making the totals—

A .. .. 117·37 c.c. N (corr.).
B .. .. 117·46 „
C .. .. 118·84 „

theory for 0·41636 grm. ammonium carbamate requiring 119·46 c.c. There is always a loss of about 8 per cent of nitrogen in estimations with hypobromite* : if this correction be applied the agreement will be still closer.

In order to facilitate the interpretation of the results, further experiments were made in the same direction, using mixtures of carbamate and water in simple ratios of their molecular weights.

	Grm. am. carb.		Grms. water.		Mols. of carbamate.		Mols. of water.
(*a*)	0·3270	with	15·09	corresponding to	1	:	200
(*b*)	0·1836	„	12·71	„	1	:	300
(*c*)	0·1307	„	12·06	„	1	:	400
(*d*)	0·1042	„	12·02	„	1	:	500

After standing for some days under similar conditions the following results were obtained :—

	C.c. of N (corr.) obtained.	Theory for total nitrogen.	Hydration.
(*a*)	82·02	93·80	0·7487
(*b*)	47·29	52·66	0·7962
(*c*)	34·57	37·49	0·8447
(*d*)	28·62	29·89	0·9156

Another experiment was made in which the ratio of the molecular weights was nearly 1 : 1, namely, 0·2614 grm. ammoni m carbamate with 0·0632 grm. water. After standing for two days, 49·52 c.c. nitrogen (corr.) were obtained—theory for total nitrogen requiring 75·0 c.c. The hydration was therefore 0·3187.

It follows from the above results that the hydration is a function of the number of water molecules present. So far the minimum hydration corresponds to the case in which the substances are present in about equal molecular proportions, and is in this respect analogous to the combination of iodine with hydrogen† and of phosphorus trichloride with chlorine.‡ From analogy it was to be expected that the hydration would again increase as the ratio of the ammonium carbamate molecules to those of water increased; but the experiment cannot be made under the same conditions as those above, since with any appreciable excess of the carbamate the water is insufficient to completely moisten the solid.

* Russel and West, *Chem. Soc Jour.*, 27, 749

† Lemoine, "Equilibres Chimiques entre l'Hydrogène et l'Iod Gazeaux," *Ann. Chem. Phys.*, [5], xii., 145.

‡ Wurtz, *Comptes Rendus*, lxxvi., 602.

III. *Influence of Temperature.*

The above results may be taken as representing the phenomena which occur at about 20 to 22° C., from which the temperature varied but little throughout the experiments.

In order to gain some idea as to the effect which temperature might have upon the action, two equal volumes of an arbitrary solution of ammonium carbamate were taken and kept in sealed vessels, one at the temperature of the room—about 15° C., and the other in melting ice. After about five hours the solutions were examined by the hypochlorite method, taking care to keep the apparatus in each case as nearly as possible at the respective temperatures.

Solution at 0° C. gave 68·0 c.c. N (corr.).
„ 15 „ 79·4 „

Similar pairs of experiments were made with another solution at stated intervals, equal volumes being measured out in the first instance and then subjected to the respective temperatures in sealed vessels.

Solution at 0°.

After 30 minutes gave 63·7 c.c., solution at 15° gave 76·2
„ 1 hour „ 73·0 „ „ 83·2
„ 2 hours „ 74·0 „ „ 88·9
„ 4 „ „ 76·3 „ „ 90·6

The hydration is therefore, in all cases, less at the lower temperature.

The minimum hydration will probably occur at a sufficiently low temperature, and when the substances are present in equal molecular proportions. A mixture was made of 0·6199 grm. ammonium carbamate with 0·1424 grm. of water—corresponding almost exactly to equal molecular weights. This mixture was kept in a sealed tube placed in a block of ice for eighteen hours, when it may be safely assumed that the equilibrium state was arrived at. It was then examined by the hypochlorite method (the apparatus being kept at about 0° C. throughout), and yielded 95·90 c.c. of nitrogen (corrected). Theory for total nitrogen requires 177·1 c.c., so that the hydration is represented by 0·0830.

Probably, at a sufficiently low temperature the hydration would be practically *nil*, when the substances are present in molecular proportions—*i.e.*, ammonium carbamate and water would practically *not combine at all*—resembling the cases of phosphorus trichloride and chloride, &c., at sufficiently *high* temperatures.

IV. *Dehydration of Normal Ammonium Carbonate.*

The salt was prepared by the method of Divers.* About 5 to 6 grms. of it were dissolved in water, and the solution made up to 100 c.c. (A). Portions of this solution were diluted to ½ (B) and 1/10 (C). After two days—

5 c.c. of A gave 35·54 c.c. N (corr.)
10 „ B „ 38·10 „
50 „ C „ 40·85 „

Equal volumes of another solution were examined at intervals, with the following results :—

After 5 minutes 67·94 c.c. N (corr.) were evolved.
„ 40 „ 66·73 „ „
„ about 3 hours 62·52 „ „
„ „ 24 „ 62·28 „ „

These results indicate that normal ammonium carbonate undergoes dehydration into carbamate when in solution, and that the dehydration is greater as the relative number of water molecules is less.

The instability of normal ammonium carbonate, and the difficulty of obtaining it free from adhering impurities, has, for the present, prevented me from making more extended observations on this part of the subject. It

* *Chem. Soc. Jour.*, 23, 179.

seems not unlikely, that if the same relative number of molecules could be started with, the same equilibrium state between carbamate, carbonate, and water, would be arrived at for the same temperature, whether ammonium carbamate or normal carbonate were initially taken—that is, that the curves of hydration and dehydration would meet at the same point. I hope before long to be able to make experiments in this direction.

Since there is this tendency for ammonium carbonate to become in part dehydrated in aqueous solution, and for the system to come to a state of equilibrium where the carbamate and carbonate co-exist, it seems probable that the hydrolysis of urea, under the action of ferments, &c., may be less simple than is usually represented—that the reaction, instead of being simply—

$$CO(NH_2)_2+2H_2O=CO(ONH_4)_2,$$

may be of the following type :—

$$nCO(NH_2)_2+(2n-m)H_2O=mCO(NH_2)(ONH_4)+(n-m)CO(ONH_4)_2.$$

I propose to attack this subject by the same method as those employed above.

By means of the actions of sodium hypochlorite and hypobromite it is evidently possible and easy to estimate quantitatively *urea*, *carbamic acid*, and *ammonia*, when all are present in the same solution.

Take two equal portions of the solution to be examined, treat one with sodium hypobromite, and let the volume of nitrogen evolved (corrected for loss) $=V_1$.

Treat the other portion with sodium hypochlorite, and let V_2 = volume of nitrogen obtained.

Act upon the residue from this last experiment with sodium hypobromite, and let V_3 represent the volume of nitrogen given off (corrected).

Let x = volume of nitrogen due to urea.
" y = " " ammonia.
" z = " " carbamic acid.

Then—

(1.) $x+y+z=V_1$.

(2.) $\frac{x}{2}+y=V_2$.

(3.) $z=V_3$.

A preliminary trial of this method with a mixture of urea and ammonium carbamate gave very satisfactory results.

It appears to me that no really satisfactory method has hitherto been known by which carbamic acid could be detected and estimated in presence of urea and ammonia, so that the process indicated above may perhaps be of service in investigations bearing on the formation of urea in the animal body, and its origin, whether carbamic or otherwise.

THE DETERMINATION OF GLYCERIN.

By WILLIAM FOX and J. A. WANKLYN.

During an investigation on the constitution of oils and fats, with which we are engaged, it became necessary to make a number of glycerin determinations, and as experiment proved the ordinary methods to be inaccurate, we worked out the method given below, and which is based on the fact that glycerin, oxidised with permanganate of potash in a strongly alkaline solution, gives oxalic acid according to the equation

$$C_3H_8O_3+O_6=C_2H_2O_4+CO_2+3H_2O.$$

The oxalate can be precipitated by a lime salt, and the amount of oxalic acid determined, and the equivalent quantity of glycerin calculated therefrom.

We carry the process out as follows :—

The aqueous solution of glycerin (which should not contain more than 0·25 grm. $C_3H_8O_3$) is made strongly alkaline by adding 5·0 grms. of solid caustic potash; powdered permanganate of potash is then gradually added until the solution is of a permanent pink colour; the solution is now kept at boiling point for half-an-hour, and then the excess of $K_2Mn_2O_8$ decomposed with sulphurous acid, either in solution or the gas may be used. The solution, which should now be colourless, is filtered from the precipitated oxide of manganese, and made acid with acetic acid and boiled; a lime salt is added, and the resulting oxalate collected on a filter and thoroughly washed with boiling water. As the precipitate is not pure oxalate of lime, we determine the oxalic acid in the lime salt by titrating with standard $K_2Mn_2O_8$ in the usual way; with a moderate amount of care this process is very accurate; the difference in several experiments should be under a half per cent, and Messrs. Benedikt and Zsigmondy, since we suggested the process, have obtained very satisfactory results, which they publish in the *Moniteur Scientifique Quesneville*, vol. xv., October, 1885.

In the saponification of fats in which it is proposed to estimate the glycerin, care should be taken to have the whole of the alcohol driven off, as dilute alcohol treated with alkaline permanganate gives oxalic acid. It may be mentioned that the acids of the acetic series do not oxidise to oxalic acid with alkaline permanganate, whilst those acids of the acrylic series do.

Laboratory, 4, Great Tower St., E.C.,
December 29, 1885.

COLOURED REACTIONS OF PHENOLS WITH CARBOHYDRATES.

By ANTON IHL.

These reactions are produced by adding the pulverised carbohydrates to an alcoholic solution of the phenol.

α-Naphthol gives with cane-sugar at a gentle heat a splendid reddish violet colour, which disappears on the addition of water; with milk-sugar a fine violet and with starch a dark red violet.

β-Naphthol gives with cane-sugar a yellow, which on prolonged boiling turns a dark greenish yellow with a greenish fluorescence; with milk-sugar, a pure yellow without fluorescence; with glucose, a yellowish green colour with a strong green fluorescence; with dextrin, a yellowish; with arabin, a light yellow; and with starch, a faint yellow.

Resorcin gives with cane-sugar an intense fiery red, which retains its colour on dilution with water; with milk-sugar, glucose, dextrin, arabin, and starch, yellowish red.

Pyrogallic acid gives reactions very similar to those of resorcin.

Phloroglucine gives with cane-sugar, on gently heating, an intense yellowish red colour, which became a fine light yellow on dilution with water; with milk-sugar a reddish brown; with glucose, a yellowish red; with dextrin, a slight dirty yellow; with arabin, on prolonged heating, an intense cochineal-red pigment, which is permanent on the addition of water.

The phenols are also well adapted for the detection of woody matters. They are used in an alcoholic solution, mixed with hydrochloric or sulphuric acid, and applied either cold or hot to the paper or wood in question.

Solution of orcin mixed with hydrochloric acid gives a splendid dark-red on wood; upon paper containing wood-stuff it gives a dark red-violet spot. Pure cellulose-paper undergoes no change.

Resorcin with alcohol and hydrochloric acid colours wood-stuff paper a violet-blue in a short time. Pure cellulose-paper remains unaffected. Resorcin with alcohol and sulphuric acid (one vol. alcohol, one-third vol. sulphuric acid), when warm, colours wood-paper or wood a dark violet-blue. Pure cellulose-paper is coloured an onion-red.

α-Naphthol in alcohol and hydrochloric acid colours wood-stuff paper and wood greenish.

α-Naphthol, in equal volumes of alcohol and sulphuric acid, colours wood-stuff paper a dark green, whilst pure cellulose-paper takes a red-violet.

Pyrogallic acid in alcohol and hydrochloric acid colours wood-stuff paper and wood a bluish green.

Carbolic acid in alcohol and muriatic acid colours wood and paper containing wood a yellowish green.—*Zeit. f. Anal. Chemie* from *Chemiker Zeitung*.

A THEORY OF THE CONNECTION BETWEEN THE CRYSTAL FORM AND THE ATOM COMPOSITION OF CHEMICAL COMPOUNDS.*

By WILLIAM BARLOW.

(Concluded from page 6.)

I WILL now deal with a more complex case, that of compounds composed of three kinds of atoms present in the proportions 1 : 2 : 3.

Since, when infinite numbers of three sorts of small bodies present in these proportions are taken, half of the bodies are of one kind, it is evident that a symmetrical disposition of these, the most numerous kind, will be made if they have the arrangement of one of the sets of bodies in one of these two systems for two kinds of bodies in equal numbers (Figs. 3 and 4). Consequently we shall

FIG. 3.

FIG. 4.

have a symmetrical system for the three kinds if we can arrange the two less numerous kinds in a symmetrical manner, so that together they shall fill the places of one set of bodies in one of these two systems.

Now the centres of the balls *of one colour* in this stack (Fig. 3) have a similar arrangement to that of the centres of *all the balls* in this one (Fig. 4), and the centres of the balls of *one colour* in this one (Fig. 4) have a similar arrangement to that of the centres of all the balls in either of these three stacks (Figs. 6, 7 and 10). And if we remove a corner from this stack (Fig. 4) we see that this system, like the systems of these other stacks (Figs. 6 to 11) may be regarded as made up of plane systems of points arranged triangularly (see Fig. 12). Thus, then, in both these stacks (Figs. 3 and 4) balls of two colours

FIG. 6.

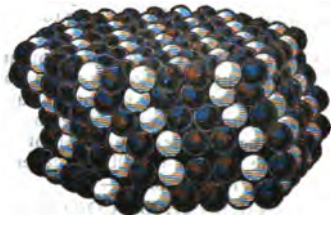

FIG. 7.

present in the proportions 1 : 2 can be arranged with perfect symmetry to fill the positions at present occupied by balls of one colour.

FIG. 8.

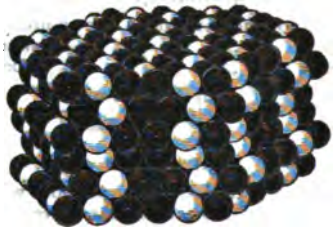

FIG. 9.

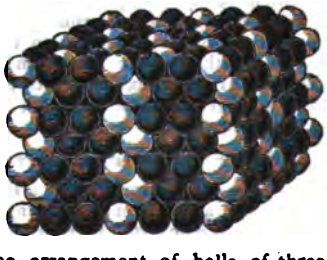
FIG. 10.



When the arrangement of balls of three colours in these various ways is accomplished, we have obtained six distinct typical symmetrical systems of arrangement of three kinds of small bodies present in the proportions

* A Paper read before Section B, British Association, Aberdeen Meeting.

1 : 2 : 3, three according to each of the two systems (Figs. 3 and 4).

Again, three other typical systems for atom combinations of this kind are obtained if we place at the centres

FIG. 11.

of the spaces between the bodies in the three infinite systems of two kinds of small bodies present in the proportions 1 : 2, depicted by these three stacks (Figs. 6, 7, and 10), a third kind of small body, the systems thus obtained

FIG. 12.

—like the three systems from which they are derived—will evidently two of them be uniaxal, the third trimetric. The latter, derived from this form (Fig. 10), is here depicted (Fig. 13).

FIG. 13.

As in all the nine systems I have thus indicated, the arrangement of the different colours will evidently not be symmetrical about three axes at right angles to one another, as it is in these two systems (Figs. 3 and 4), we must, as in the other cases of symmetry already referred to which are not of the cubic system, employ spheroids or ellipsoids in place of spheres, if we wish to depict the precise symmetrical form proper to any particular case.

In six out of the nine the symmetry is uniaxal, and therefore similar spheroids would be used. In the remaining three cases the symmetry is trimetric, and suitable similar ellipsoids would have to be employed. As before, the form of spheroid or ellipsoid to be used would depend on the kinds of atoms associated in the compound.

I remarked just now that if calcium has but half the atomic weight usually attributed to it, the composition of Iceland spar would be in harmony with its crystal form. I will now proceed to show this.

In this case Iceland spar would be an example of the kind of compound which we have just been considering, for it would contain 1 atom of carbon, 2 atoms of calcium, and 3 of oxygen. (What follows would apply equally well if it contained 1 atom of calcium, 2 atoms of carbon, and 3 of oxygen.)

Now four of the six systems for compounds of this kind which I just now derived from these two cubic systems (Figs. 3 and 4) are symmetrical about a single axis which has the direction of one of the diagonals of the cube outlined by the stack; and when we employ appropriate symmetrically placed spheroids instead of spheres, we shall therefore, in either of these four systems, have a rhombohedral form in place of the cubic. This is in harmony with the fact that Iceland spar crystallises in rhombohedra.

It is interesting to notice that in two of the four systems which I have just referred to, those two which are derived from this system (Fig. 3), we have one kind of small body—that which represents the oxygen atoms—ranged in planes having directions exactly corresponding to the directions of cleavage of crystals of Iceland or calc spar.

The dimorphic form of the same compound, known as aragonite, would be referred to one of the three *trimetric* systems of symmetry which I have just traced.

It is evident that, if we pursue the methods I have thus indicated, a very great variety of symmetrical arrangements of different kinds of small bodies present in various different given proportions may be derived from the few symmetrical systems of arrangement of points in space of which the models before you are examples. Thus, as another example, we have here a symmetrically arranged plane system of balls of two colours present in the proportions 1 : 3 (Fig. 14). And when these are built up to

FIG. 14.

show the arrangement for compounds of two kinds of atoms present in these proportions, the system produced will be found in harmony with the crystal form of several of such compounds. The very simple symmetrical systems of arrangement of points in space I have selected as typical systems, from which to derive symmetrical arrangements for different atom proportions, are five in number (Fig. 3 gives one system; Fig. 4 gives a second; Figs. 6, 7, or 10, a third; Figs. 8, 9, or 11, a fourth; and Fig. 13 a fifth).

The reason for my selection of these particular systems is that they exhibit far greater evenness of distribution of the points than is found in any other symmetrical system of points in space. For four of them are distinguished from all other symmetrical systems by the property that if the nearest points grouped around any point of a system are joined, the solid thus outlined has its edges all equal; and the fifth (Fig. 13) is distinguished by the property that, in the case of some of the points, when the nearest points grouped around any one of them are joined, the solid outlined has equal edges, and in the case of the re-

maining points, when the next nearest points are joined, this is the case.

I would suggest that these five systems probably furnish all the types from which all the systems according to which the atoms of crystallising compounds are arranged can be derived, the relative distances between the atoms, and consequently the relative dimensions of the actual systems in different directions, depending, however, on the kinds of atoms present, and their relative numerical proportions.

In referring all systems to these few types, there is, however, one observation that I ought to make. The symmetry of a system of different kinds of small bodies will evidently not be impaired by the removal of all the similarly situated bodies of a given kind. For instance, the symmetry, as to the arrangement of colour, of this system (Fig. 13) would be equally great if all the least numerous kind of balls were removed, the balls of the other two kinds remaining in the same positions. Now I suppose that where the relative numbers of different atoms present is not such as to allow of their arrangement to fill all the places in a symmetrical system such as is here depicted, a set or sets of symmetrically situated places in the system may be left unoccupied.

Thus the atoms of a compound of two kinds of atoms present in the proportions 2 : 3 might, I suggest, be arranged according to this system (Fig. 13), the places marked by the centres of the least numerous balls being left vacant.

The disposition in space in such cases would not be so even as when all the positions are occupied, but would be improved if the atoms slightly closed in upon the vacant spots in a symmetrical manner.

Several compounds of two kinds of atoms in the proportions 2 : 3 crystallise in six-sided prisms or in rhombohedral forms (*e.g.*, Al_2O_3 in six-sided prisms; Fe_2O_3,Cr_2O_3 in rhombohedral prisms.

Where many different kinds of atoms are present it is probable that the symmetry of disposition reached is not perfect with respect to all the different varieties of atoms, but that atoms of allied kinds to some extent occupy similar positions almost indiscriminately; perhaps for the purpose of symmetrical disposition, the atoms fall into three or four classes.

This view is countenanced by some o the facts of isomorphism.

Before closing I may call attention to a few other facts concerning crystals as supporting my theory.

Thus there are close resemblances between the different types. For example, four of our five arrangements of points in space may be regarded as made up of similar plane systems of points triangularly arranged. The result of this similarity evidently is that the atoms of a given compound have to make but a slight change of their relative positions in order to pass from one system of possible arrangement to another, and this fact seems to throw light on the readiness with which dimorphic changes occur in some cases.

As an instance of this readiness I may refer to the familiar fact that mere contact with foreign bodies sometimes causes rhombohedral crystals of saltpetre to become turbid, and effects their transformation to crystals of a prismatic form.

Again, the occurrence of dimorphism is in harmony with that variety in the types of symmetrical arrangement of the same atom-combination which I have shown to be possible, and this variety of types further accounts for the variety of forms presented by different compounds whose atom proportions are similar.

The cause of dimorphism we may suppose to be that in some cases slight changes in the relative degrees of attraction and repulsion, exercised by the different atoms of a compound on one another, cause stable equilibrium of their various forces to be found in a different system of symmetry.

The fewness of our types is consistent with the fact of very diverse compounds crystallising according to the same system.

I suppose that the faces of crystals have the direction of planes which contain a large number of the symmetrically situated points. Thus the faces of cubes indicated by their stacks (Figs. 3 and 4) have the directions of planes containing the centres of all the outlying balls, and the faces of octahedra indicated by this one (Fig. 15)—in

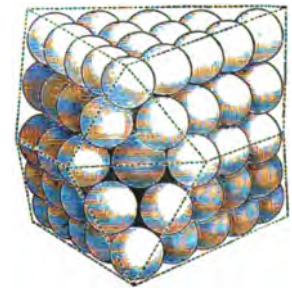
Fig. 15.

which the centres are as in these three (Figs. 8, 9, and 11)—have the directions of planes containing the centres of the outermost balls.

That this relation between the directions of crystal faces and the supposed symmetrical arrangement of the atoms in space subsists is entirely supported by the law of the rationality of the parameters; for if we examine stacks of sufficient magnitude, we find that the series of plane directions actually exhibited by crystals of the same substance are those, and those only, which will fulfil this condition, that they intersect a large number of the symmetrically placed points.

In cases of hemihedral and tetrahedral forms we may suppose that the directions of the faces omitted and the directions of the corresponding faces existing intersect different sets of atoms. For example, in these two hexagonal forms of arrangement of two kinds of atoms (Figs. 8 and 9) pyramid planes drawn to three alternate prism faces do not in any case intersect similar plane systems of atoms to those intersected by pyramid planes drawn to the remaining three prism faces.

Fig. 16.



The difference of bulk produced in any crystal by a change of temperature we shall naturally attribute to changes in the values of the forces of attraction and repulsion exercised by the different atoms on one another; and in harmony with this we shall refer the fact of crystals not of the cubic system expanding in different degrees in different directions according to their symmetry, to the attractions and repulsions exercised by the different kinds of atoms changing differently when a change of temperature takes place.

The phenomenon of the formation of twin crystals is in

harmony with my supposition that the atoms in crystals are very evenly distributed in space; for it will be found that the modification of the distribution of the atoms indicated by this phenomenon is not such as perceptibly to impair the evenness of distribution.

To illustrate this. In this arrangement of balls showing an octahedral form (Fig. 15) the balls are arranged according to the third of our five typical arrangements of points in space. When I remove the balls down to the middle layer I get a hexagonal plan, and I have only to shift the upper balls round bodily through 60°, and place them in a precisely similar way upon the lower balls, and we get the twin form (Fig. 16).

My supposition that the arrangement of the atoms of a crystallising body symmetrically takes place gradually is countenanced by the fact that the longer the process of crystallisation is about the larger the crystals produced. For the natural explanation of this, according to my theory, is that the longer any mass, whose atom composition is such as to allow of the formation of crystals, continues in a state of transition from a liquid to a solid condition, the greater the opportunity for the passing waves of condensation and rarefaction to perfect the symmetrical distribution of the different kinds of atoms, *and to make it continuous over larger spaces.*

With reference to the crystallisation of the elements, it is clear that the effect of waves of alternate condensation and rarefaction, where one kind of atom only is present, will be to produce the simplest, most compact, kind of arrangement possible,—that in which each atom is equidistant from twelve surrounding atoms (Fig. 15).

The greater number of the elements crystallise in octahedra, which harmonises with this view.

Where they crystallise according to other systems than the regular system, my theory appears to oblige us to conclude that, under the conditions prevalent at the time of crystallisation, they contained different kinds of atoms, or atoms having different definite states.

In closing, just a word or two as to isomorphism.

Apart from the distribution of colour, three of our five fundamental systems are symmetrical about three axes at right angles to one another (Figs. 3, 4, and 15), and it is evident that a number of atom combinations will be capable of a perfectly symmetrical arrangement with respect to these three axes, according to one or other of these three systems. All compounds whose different atoms can be thus symmetrically arranged with respect to three axes we shall expect to crystallise according to the cubic system, and thus to be isomorphous with one another.

As to other cases of isomorphism, it supports my theory that, as a rule, the isomorphous bodies contain similar proportions of some of the same elements, *e.g.*, calc spar and spathic iron ore.

It is natural to suppose that here the symmetrical systems are similar in the different compounds, and that the atoms common to both have identical dispositions. But it will be asked, How is it that the attractions and repulsions exercised by the atoms which are not common to the different isomorphous compounds do not cause the departures from the root or type form to be very perceptibly different in different compounds? I remark, in reply, that where great symmetry prevails in a system of several kinds of atoms, a considerable variation in the attractions and repulsions exercised by *one* kind on the rest would not necessarily alter the form of the system materially. In other words, the fact of the attractions and repulsions exercised by one set of atoms being different from those exercised by the corresponding set of atoms in a compound isomorphous to it may not produce a perceptible difference of form of the symmetrical systems according to which the atoms are respectively arranged.

In cases where the atom composition of isomorphous bodies is very different, I suggest that the atoms common to both may nevertheless have the same disposition.

Take the case of ammonic sulphate, $(NH_2)_2H_2SO_4$, being isomorphous with potassic sulphate, K_2SO_4.

In this case I suppose that the symmetrical arrangement in the former compound is such that the groups $(NH_3)_2$ occupy places which might, without altering the disposition of the remaining atoms be filled by additional groups H_2SO_4; that, in other words, the relative position of the groups H_2SO_4 is precisely the same as it would be if the entire mass consisted of these groups.*

METHODS OF BUTTER ANALYSIS.†

By H. B. CORNWALL.

Three of the commoner methods for examining butter fats by more or less thorough quantitative determination of the fatty acids obtainable by decomposition of the fat, or by allied operations, have been tried by the writer: Hehner's (as well as a modification of it described by Blyth—"Foods, their Composition and Analysis," London, 1882), Reichert's, and Koettstorfer's.

Hehner's process (*Zeitschrift f. Analytische Chemie*, 1877, p. 145) is discussed. His statement that the insoluble acids from 3 grms. of fat will ordinarily require three-quarters of a litre of boiling water is probably true, but Fleischmann and Vieth (*Fresenius' Zeitschrift*, 1878, p. 287), and A. Hanssen ("Inaugural Dissertation," Erlangen, 1882) are quoted to show that 2 to 3 litres of water may be required, and that certain precautions may be necessary in washing.

Hehner's highest limit of 88 per cent of insoluble fatty acids in butter can only be accepted as applying to the great majority of cases. Several writers state that this limit may be too low. Fleischmann and Vieth (*loc. cit.*) set the limit at 90, having found a butter yielding 89·73 per cent. They also quote the *Journal of the Royal Agricultural Society*, 1877, to the effect that Bell found the limits to vary between 85·5 and 89·8. Kretzschmar (*Berlin Berichte*, 10, 2091,) found several butters yielding over 89 per cent, and thinks the highest limit should be 90. (Kuleschoff (Wagner's *Jahresbericht*, 1878, p. 999,) obtained 89·72 per cent. Jehn (*Archiv der Pharmacie*, ix., 1878, 335) found 89 or more per cent. in three out of ten butters, and although he used wax to collect the insoluble acids, yet his results do not show that this deviation was the certain cause of his high figures.

De la Source (Wagner's *Jahresbericht*, 1882, 929) found 89·1 and 89·4 per cent, and objects to the French standard of 88 per cent as too low.

On the other hand, R. W. Moore (Chemical News, December 5th, 1884) found cocoa-nut oil to yield only 86·43 per cent of insoluble fatty acids by Hehner's method, and the writer's experiments tend to confirm his statement. The writer found that the soluble fatty acids could only be very slowly removed from the insoluble fatty acids in the analysis of cocoa-nut oil, even with boiling hot water.

The writer also tried the modification of Hehner's method described by Blyth (*op. cit.*) on cocoa-nut oil, and even with purposely imperfect washing of the insoluble acids (1050 c.c. of wash water in all), found 89·7 per cent of insoluble acids and 3·44 per cent of soluble. The low total, 93·14 per cent, may be due to the persistent loss of weight of the impure insoluble acids in drying on the water-bath. A constant weight could not be obtained. As it was, the cocoa-nut oil would have passed for three-fourths pure butter. It had, as purified by the writer, a bland taste, and was almost absolutely odourless. Moreover, Jeserich and Meinert (Wagner's *Jahresbericht*, 1882,

* The Author has offered an explanation of the nature of chemical combination in his "New Theories of Matter and of Force," published by Sampson, Low, and Co., London.

† Abstract prepared by the Author from the Report of the State Board of Health of New Jersey, U.S.A., for 1884.

932) have patented a process by which they claim that an odourless fat is obtainable from cocoa-nut oil, palm-nut oil, &c., edible and suitable for making artificial butter.

In any event, Hehner's process, pure and simple, must be held incapable of distinguishing cocoa-nut oil in mixtures, if not alone, from true butter fat.

Koettstorfer's method (*Fresenius' Zeitschrift*, 1879, 199), depending on the larger amount of alkali required to saponify butter fat in comparison with a very large number of other animal and vegetable fats, has been shown by Moore (*loc. cit.*) to be unreliable when applied to mixtures containing cocoa-nut oil. Moore mixed cocoa-nut oil and oleomargarine, in proportions previously calculated by himself, and the mixtures, free from butter, gave figures falling between the lowest and highest limits fixed for genuine butter by Koettstorfer.

Reichert (Fresenius' *Zeitschrift*, 1879, 68), devised a method, based on the facts reported by Hehner, and his method consists in determining the acidity of the distillate of soluble fatty acids and water, obtained under constant conditions. The melted fat is filtered, 2·5 grms. of it weighed in a flask of about 150 c.c. capacity, 1 grm. of solid caustic potash and 20 c.c. of 80 per cent alcohol are added, and the whole heated to gentle ebullition on a water-bath with frequent agitation. The alcohol is evaporated on the water-bath, and the heating thus continued until the resulting soap is absolutely free from alcohol. This result may be hastened, toward the end, by placing the flask within the water-bath and sucking out the vapours until they retain not the slightest taste of alcohol. The soap mass should be nearly dry at last, since the removal of all alcohol is essential. Afterwards 50 c.c. of water is added to dissolve the soap, and when *completely* dissolved and cooled the soap is decomposed in the flask with 20 c.c. of dilute sulphuric acid (one of pure strong acid to 10 of water, by volume). The flask is connected with a small but efficient Liebig's condenser, and the contents heated to gentle boiling, bumping being prevented by adding a platinum wire spiral with a bit of pumice-stone on each end (Caldwell's device). The tube connecting the flask and condenser should be moderately wide (about 7 millim. bore) and reach about 3 inches above the flask before bending. This will effectually guard against mechanical carrying over of sulphuric acid, while not causing undue condensation in the tube. Its lower end should be ground slanting. The distillate is to be passed through a small wet filter (to hold back some insoluble fatty acids that come over) and collected in a 50 c.c. flask. As soon as 10 to 20 c.c. has come over it is returned to the first flask, and then the distillation is continued until 50 c.c. has come over. This is *at once* to be titrated with decinormal alkali solution, which is added until litmus solution (4 drops as an indicator) assumes a permanent blue colour, permanent for a few minutes. Phenol-phthalein may also be used.

The potash need not be weighed closer than to about 1 centigramme, nor need unnecessary caution be used as to the strength of the alcohol, but the method is a strictly comparative one, and must not be arbitrarily altered. Duplicate determinations are exceedingly satisfactory by it. The loss by escape of butyric ether during saponification is inappreciable, as experiment proved.

Great differences may result if the sulphuric acid is added before the soap is all dissolved, and blank tests should be made with the potash and alcohol alone, to determine what acidity in the distillate is due to them.

Reichert consumed, on the average, 14 c.c. of decinormal alkali, and never less than 12·5 c.c. His formula for determining the percentage of butter-fat in mixtures is $B = 7{\cdot}3\ (n - 0{\cdot}3)$; n being the number of cubic centimetres of decinormal alkali used in titration.

Meissl (*Dingler's Polytechn. Journal*, 1879, 229) slightly modified the method, especially by using double quantities of fat, &c. His results agree essentially with Reichert's, but the writer regards his modifications as cumbersome and unnecessary. Ambühl (Wagner's *Jahresbericht*, 1881, 839) used 14·05 to 15·55 decinormal alkali for 2·5 grms. of fat; Medicus and Scherer (*Fresenius' Zeitschrift*, 1880, 159) recommend the process. They, as well as Meissl, observed that the more fusible part of genuine butter, separated from the rest by partial cooling, might yield higher figures; 17·3 c.c. instead of 14 c.c., in one experiment.

Sendtner (*Wagner's Jahresbericht*, 1883, 979), by Meissl's method, obtained as a range through a year's time, figures varying from 24·25 to 32·25, the lowest results in February and July. He would place the lowest limit at 24 c.c. (or by Reichert's method 12 c.c.), but would not at once condemn a butter requiring 23 to 23·5 c.c. (11·5 to 11·75 by Reichert).

The writer's results also corresponded with Reichert's, ranging from 12·9 to 14·5 on butters made by himself. Oleomargarine butters gave from 0·4 to 1·55 c.c. Reichert obtained for rape-seed oil 0·25 c.c.; for lard 0·3; for kidney fat 0·25.

Beckurts (*Pharm. Centralhalle*, 1883, 557), following Reichert's method, used from 15·6 to 17·5 c.c. of decinormal alkali, and thinks Reichert's standard too low. His results are unique, and, in the writer's opinion, need confirmation. A. Hanssen (*op. cit.*) and E. Reichardt (*Archiv der Pharmacie*, 222, 1884, 93) also confirm Reichert's figures. Reichardt's experiments were with cows of Dutch breed, using every variety of fodder, and his tests included butter made in every month of the year. He also states that Birnbaum, in Baden, never required less than 13 c.c. decinormal alkali, at whatever season of the year.

Munier alone (*Fresenius' Zeitschrift*, 1882, 394) has proposed to lower Reichert's standard, or, at least, the standards of Meissl and Sendtner. He worked on butters at Amsterdam, Holland, and concluded that the standard should vary for different months. His lowest standard would be 10 c.c. from October to March; but he found in December one butter as low as 9·2 c.c. Why did he not at once propose to lower the standard to 9.2 c.c. for December at least?

Munier's figures are not reliable, because he varied from Reichert's method; especially in using very much less alcohol, and also weaker. Moreover he decomposed the soap with phosphoric acid solution. He called his modifications unessential, but Sendtner (*loc. cit.*) rejects his results altogether, and Reichardt also condemns his deviations, unsupported as they were by published comparative tests to prove that they yielded results identical with Reichert's original method.

Direct comparison of Reichert's and Munier's methods were instituted in the laboratory under the writer's charge.

With phosphoric acid prepared from glacial acid by long boiling with water, extremely low figures, often as low as 6 or 7 c.c., were obtained. With Merck's phosphoric acid better results were obtained, but all fell from 1·1 c.c. to 0·2 c.c. too low, except in one instance where there was only a difference of 0·05 c.c. Six butters were so tested. Munier's figures cannot be received as conclusive until they have been confirmed by further tests.

The essential feature of Reichert's process is the limited fractional distillation. To distil so long as any acid comes over would be to lose the whole advantage of Reichert's process. Cocoa-nut oil yielded to the writer, by Reichert's method, a distillate requiring 3·5 c.c. of decinormal alkali. On adding 50 c.c. more of water to the decomposed soap solution, and again distilling off 50 c.c., a distillate was obtained requiring 2·3 c.c.; repeating the addition of 50 c.c. of water and again distilling off 50 c.c., 1·5 c.c. of decinormal alkali was required; the fourth trial gave 1·4 c.c.; the fifth, 1 c.c.; the sixth, 0·9 c.c., and at this point the experiment was stopped. A genuine butter similarly treated required for the first distillate of 50 c.c., 13·6 c.c. of decinormal alkali; for the second, 1·65 c.c.; for the third, 0·45 c.c., for the fourth, 0·25 c.c.,

at which point the experiment was stopped. No further argument seems necessary for adopting Reichert's plan.

The writer is convinced that Reichert's is the only one of the three methods mentioned that is with any practical degree of accuracy capable of distinguishing between cocoa-nut oil, in mixtures or alone, and pure butter fat. It is rational and convenient.

Reichert's method, with a slight lowering of the standard, is applicable to very rancid butters. About one-half pound of butter, which in May gave a distillate requiring 13·8 c.c. of decinormal alkali, was kept in a loosely-covered jar in the laboratory for eight months, the thermometer rising at times above 90° F. (32° C.). It was then very rancid, smelling like cheese, mouldy on top, and partly changed to a brown mass. An average sample now required 13 c.c. of the decinormal alkali.

NOTICES OF BOOKS.

Chemistry, General, Medical, and Pharmaceutical: including the Chemistry of the British Pharmacopœia. A Manual of the General Principles of the Science and their Applications in Medicine and Pharmacy. By JOHN ATTFIELD, F.R.S. Eleventh edition. London: Van Voorst.

ON opening this book we were struck with the "Advice to Students" here inserted. The writer protests against studying merely by way of "preparation for examination." But he seems to think that a mastery of any subject will enable the student to "pass" with ease and pleasure—an opinion which we by no means share. Dr. Attfield admits that "all authorities on education regard examination as but a partial test of knowledge and an imperfect test of education." He might have added "and as no test at all of mental fertility and of the power of origination." But by way of neutralising the above important concession, he writes:—"It is the best, however, that has been devised." This we cannot admit, as far as the physical sciences are concerned. The reports of professors who have watched the student in their several laboratories will throw a far clearer light both upon his knowledge and his powers than the conclusions of examiners who have seen him only under unfavourable circumstances.

The work before us does not enter into the chemistry of all the elements, those which are of little importance in pharmacy and medicine being passed over. This is perfectly legitimate, but it is scarcely satisfactory to give the name "analytical charts for *all* metals" to tables in which nearly half of them are wanting. By an oversight, no mention is made of the formidably poisonous properties of the chromium compounds, which, as it is well known, are now manufactured and used in the arts on a very large scale.

In the portion of the work which discusses organic compounds we note a few defects. Thus, carmine is said to be "carminic acid united with 1 or 2 per cent of alumina, or occasionally of oxide of tin or albumen." C. Liebermann considers that the tin and traces of copper when present are derived from the vessels in which the cochineal has been boiled, whilst alumina and lime are present, each to about 3½ per cent.

Under "Cantharidine" we note a clerical or typographical error. *Mylabris cichorii* is given as *Mylatris*.

The short section on colouring matters—which, of course, are but of secondary importance to the pharmaceutist—is not quite free from error. Thus fustic is said to be the wood of *Rhus cotinus*. In fact it is yielded by *Morus tinctoria*, the product of *Rhus cotinus* being known as young fustic, or fustet, and giving different results with mordants and other reagents. The best quality of Persian berries are the product, not of *Rhamnus infectorius*, but of *R. amygdalinus*, *R. oleoides*, and *R. saxatilis*.

We cannot admit that cam-wood contains probably the same substance as Brazil-wood and sapan. It has not, indeed, been, as yet, thoroughly examined, but in its behaviour it approximates to sanders-wood and barwood, which yield colouring matters less soluble in water and more permanent than those of the softer red woods.

Under indigo we read that it is "now produced artificially" These words might be misunderstood as meaning that the ordinary indigo of commerce is thus obtained. Bayer's artificial product cannot compete in the market with the natural article.

We are unable to endorse Dr. Attfield's remarks on methylated spirit. He speaks of it as "a spirit issued, duty free, for the use of manufacturers, the methylic alcohol, &c., not interfering with technical applications." This, unfortunately, is not the case. The impurities in wood-spirit, which the revenue officials do not allow to be eliminated, interfere with the tinctorial uses of the spirit, and still worse is the presence of shellac, which is insisted upon unless the consumer can find heavy security that the spirit shall be used merely for the purposes specified.

But, passing over these points, which after all little affect the main object of the book, we must pronounce it most satisfactory, both for its comprehensiveness and its accuracy. We are glad to note that the microscopic characters of certain organic bodies and mixtures, such as the starches and urinary sediments, are carefully described and illustrated by well-executed figures.

In fine, Dr. Attfield must be complimented on the care and patience which he has evidently brought to bear on his task. We are particularly struck with the thoroughness, and—so far as we have been able to test it—the accuracy of the index. Having had some experience in indexing, we are the better able to appreciate this feature.

Studies from the Laboratory of Physiological Chemistry, Sheffield Scientific School of Yale College. For the year 1884-1885. Edited by R. H. CHITTENDEN, Ph.D., Professor of Physiological Chemistry. New Haven: Tuttle, Morehouse, and Taylor.

THIS work marks a sound and energetic scientific activity. Professor Chittenden is evidently initiating his students in research by the German method of associating them with himself in original investigations. The efficacy of this plan, which is in fact the key-stone of the German university system, does not require to be here expounded.

The questions here examined are the diastatic action of saliva as modified by various conditions, studied quantitatively; the amylolytic action of the diastase of malt is modified by various conditions; the influence of certain therapeutic and toxic agents on the amylolytic action of saliva; the influence of various inorganic and alkaloid salts on the proteolytic action of pepsin-hydrochloric acid; the influence of certain therapeutic and toxic substances on the proteolytic action of the pancreatic ferment; the influence of temperature on the relative amylolytic action of saliva and malt-diastase: the influence of bile, bile salts, and bile acids on amylolytic and proteolytic action; the absorption of arsenic by the brain; the influence of potassium and ammonium bromides on metabolism; the influence of cinchonidine sulphate on metabolism, and the post-mortem formation of sugar in the liver in presence of peptones.

The inquiry into the absorption of arsenic by the brain are of great importance from a toxicological point of view. The authors succeed in confirming the conclusion of Scolosuboff, that arsenic when taken in a very soluble and diffusible form, such as sodium arsenite, accumulates in the brain. On the contrary, when the poison has been taken in the form of arsenious acid or copper aceto-arsenite (Paris green), which are very sparingly soluble,

mere traces are discovered in the brain. Hence in poisoning cases, where the symptoms indicate the possible presence of arsenic, the brain ought to be specially and distinctly examined. If arsenic is there recognised it may be regarded us strong evidence that the poison has been administered in some soluble form. Two recent cases, which the authors append in illustration, show that in acute poisoning from the ingestion of large doses of insoluble arsenical compounds, mere traces were found in the brain. In one case, whilst 12·78 m.grms. arsenious acid were obtained from the liver, and 3·40 m.grms. from the kidneys and bladder, the brain yielded only 0·2 m.grms.

One question the authors do not appear to have decided: if arsenious acid has been administered in small successive doses, in what proportion will it be found in the brain? Such cases in human subjects are very rarely met with, but in America experiments on the lower animals have not been prescribed by law, and the authors might therefore with advantage undertake the decision of this point.

Workshop Receipts. Fourth Series. By C. G. Warnford Lock. London: E. G. Warnford Lock.

This fourth and final series of "Workshop Receipts" is, as we are informed in the preface, devoted mainly to subjects connected with handicrafts and mechanical trades, and consequently falling to a great extent outside the boundaries of our legitimate cognisance. This is eminently the case with bookbinding, straw plait, matting and basket-making, repairing pianos, harmoniums, and musical boxes, clock- and watch-mending, &c. Indeed, it is doubtful in how far instructions for repairing clocks and watches can be looked upon as receipts. Few persons, we think, will undertake, and still fewer will succeed in such tasks, unless they have formally learnt the trades in question, when they will have little need of printed instructions.

But there is also matter which falls within the province of the chemist. There is an article on distillation viewed with reference to the purification of water from fixed impurities, to the preparation of tinctures and extracts, and to the rectification of those forms of ethylic alchohol popularly known as "spirits." A figure and a portion of letter-press are devoted to the apparatus used in Neufchatel for the manufacture of that poisonous concoction absinthe.

Desiccation is treated of both as a scientific and as a technical operation. It is strange, however, that we find here no mention of the Gibbs drying machines, which are now in successful use at the Government gun-cotton works at Waltham Abbey. We are not sure, however, whether some of the processes here described are not adaptations of some of the expired patents of the inventor.

The various pumps used in raising acids, alkaline lyes, liquid soaps, syrups, &c., are described and figured at some length.

Embalming, as applied to human bodies, little requires to be taught; indeed were it at all general it would require to be seriously untaught. But the instructions for preserving anatomical specimens are trustworthy and valuable.

"Packing and Storing" is the title of a chapter of much more interest and importance than it might at first glance be expected. It is startling to find that very large quantities of Assam tea sent to this country have been rendered of little value by the nature of the wood employed in making the chests. Some kinds of timber generate acetic acid, which reacting on the wood produces ill-smelling compounds, and not only so, but corrodes the lead lining, thus allowing the aroma of the tea to make its escape.

On filtration we find a lengthy article. The Hyatt, Atkins, Sawyer, the silicated carbon, the Bernays, the Spencer, and the Bischof filters are all described. Concerning the last-mentioned, or spongy iron filter, the author expresses himself rather too confidently: eminent authorities maintain that water thus filtered is by no means free from bacteria and other micro-organisms. Mention is also made of Chamberland's earthenware filter, which is, for certain purposes, the most efficient of all.

As regards laboratory filtration it is remarked that English manufacturers do not seem to have turned their attention to the preparation of a superior filter-paper. Munktell's Swedish and Schleicher and Schull's German papers are still preferable to anything produced in this country.

As regards the magnesia process for softening water on the large scale we entertain a doubt. If the magnesia passes into solution its presence for some technical uses, and certainly for dietetic purposes, will be more objectionable than the original calcium salts.

The entire series of "Workshop Receipts" merits, and will doubtless command, a large circulation.

Thirteenth Annual Report of the Director of the Mint, 1885. Washington: Government Printing Office.

From this report we learn that the estimated total production of gold in the world for the year 1884, calculated in American money, was 95 millions, and of silver 115 millions. This is an increase of about a million in gold over the production of 1883, and a falling off to about the same extent in the production of silver. The yield of gold is about 4½ millions less than it was in 1882.

The total coinage of the world is given as 99½ million dollars in gold and 90 millions in silver. The consumption of gold for coinage alone is thus greater than the year's supply. The total value of the gold coinage of the United States is given as close on 24 millions, and the silver coinage is 28½ millions. The gold coinage of Russia is given as nearly 20 millions, that of Germany 14 millions. The total gold coinage of the British empire is 33 millions, viz., 11 millions in England, and 22 millions in Australia.

Price-List of Chemical and Scientific Apparatus and Pure Chemicals sold by Baird and Tatlock. Glasgow: Crown Buildings, Sauchiehall Street.

We have here a copious and well-illustrated catalogue of apparatus, chemical and physical, electrical appliances figuring very prominently. Of balances Messrs. Baird and Tatlock seem to keep a large assortment in stock, of the makes of Oertling, Bunge, and Becker. They have also a large assortment of the gas-furnaces, stoves, blowpipes, &c., devised by Fletcher, of Warrington.

In looking over the list of chemicals we find mention of some substances not to be obtained from every dealer in reagents, *e.g.*, phenol-phthaleine. We notice, with some surprise, that "fuchsine" figures here not as an objectionable Franco-German synonym for the English name "magenta," but as a distinct substance. At least "fuchsine" is quoted at 2s. 6d. per ounce, and magenta at 9d.

Diaries for 1886. London: Letts, Son, and Co., Limited.

Again we have pleasure in drawing attention to the useful little publications of this firm. The pocket diaries, which are published in numerous sizes and shapes, and of different prices, contain, in addition to the usual diary spaces for entering notes and engagements, much information which if correct cannot fail to be useful, if the owner of the pocket book only remembers where to find it. Thus the Gentlemen's Pocket Diary contains, amongst other items, information about Passports, Property Tax (given at the pleasant figure of 6d. instead of 8d.), Rates, Inland

Revenue Duties, Eclipses, The Cabinet, British Customs Tariff, Stamp Duties, British and Foreign Postal Tables, Foreign Telegram Time Table, Weights, Measures, Wages, How to make a Will, Middle Class Hospitals, Tide Tables, Weather Forecasts, a complete list of members of the *late* House of Commons, &c.

The Metallic Diary, although too small for most purposes, will be useful for note taking, as the marks with the metal stylus will not rub out like ordinary pencil marks. It is not generally known that on this prepared paper writing can be effected with any silver or gold coin in default of the prepared pencil supplied with the book.

CORRESPONDENCE.

THE INSTITUTE OF CHEMISTRY.

To the Editor of the Chemical News.

SIR,—May I be allowed space for a few lines on the subject of the three years' collegiate training required by the Institute of Chemistry.

I venture to think that I am expressing the opinion of the majority of analytical chemists, when I say that this compulsory training is a great hardship to many of us, and is due to a most short-sighted and mistaken policy on the part of the Council. My own case I believe to be somewhat hard, for I have been articled for five years to an analyst with a large practice, and have therefore acquired considerable practical knowledge, and yet find myself debarred even from submitting my knowledge to the required test.

Your correspondent of the 26th instant, writing under the *nom de plume* "Ferrum," and whose case is similar to my own, said that, on applying to the secretary, he was told that the Council of the Institute insisted on the evidence of three years' training. On laying my own case before the secretary, I was even more unfortunate than "Ferrum," for no notice was taken of my letter. Cannot the Council see that the best interest of the chemical profession would be served by the abolition of the college training, and the substitution of an examination which would be a fair test of both practical and theoretical knowledge, and which would be available to any chemist?

Another grievance is that it is simply the accident of birth that shuts many men out, as prior to October, 1883, any man who had arrived at the age of 21 could, on producing certain certificates from the Science and Art examinations, sit for the A.I.C. without any collegiate preparation. Let us hope that the many letters which have already appeared on this subject will appeal with good result to the Council of the Institute of Chemistry.

I enclose my card, and am, &c.,

J. W.

CHEMICAL NOTICES FROM FOREIGN SOURCES.

NOTE.—All degrees of temperature are Centigrade unless otherwise expressed.

Zeitschrift für Analytische Chemie.
Vol. xxiv., Part 4, 1885.

Action of Chlorophyll upon Carbonic Acid outside the Plant Cell.—P. Regnard.—The chlorophyllian granules continue to decompose carbonic acid, even when separated from the plant cell. Chlorophyll separated from protoplasm acts also, although with a very feeble intensity.

Determination of Sulphur in Organic Compounds.—E. H. Keiser.—The author criticises Liebig's process.

Volumetric Determination of Acetic Acid and its Salts.—C. O. Weber.—The author heats 10 grms. of the acetate finely ground with a little water in a 50 c.c. flask, fills it up to the mark, and filters the liquid through a dry folded filter. 25 c.c. of this solution are mixed with 50 c.c. absolute alcohol, and the acetic acid is precipitated with an alcoholic solution of silver nitrate. The precipitate of silver acetate is filtered, well-washed with 60 per cent spirit, dissolved in hot dilute nitric acid, and titrated with decinormal sodium chloride. Each c.c. of this solution consumed represents 0·006 grm. acetic acid hydrate.

The Melting and Congealing Points of Mixtures of Phenol and Paracresol.—G. Lunge.—The author gives his results in the form of a table.

The Influence of Basic Lead Acetate on the Determination of Sugar by Polarisation.—P. Degener.—Basic lead acetate modifies the rotatory power of a number of bodies existing in beet-juice. The error thus occasioned is diminished by the addition of 0·3 volume of absolute alcohol.

The Volumetric Determination of Sugar with Fehling's Solution.—F. Meyer.—To occasion a quick settlement of the cuprous oxide the author adds, towards the end of the operation, a little zinc chloride.

Determination of Starch in Grain and Potatoes.—M. Maercker.—The author heats 3 grms. of the finely ground sample to 90° with 50 c.c. of water. When it has cooled down to 65° he adds 5 c.c. of a cold extract of malt. After half an hour he adds 10 c.c. of a 1 per cent solution of tartaric acid, and heats in a brass vessel up to a pressure of 4 to 5 atmospheres. When the liquid has cooled down to 65°, 5 c.c. more malt extract are added, and after another half hour the mixture is again heated for two and a half hours to 100°, with the previous addition of 15 c.c. hydrochloric acid and 150 c.c. water. The solution is then neutralised, and the dextrose formed is determined by Allihn's method.

Analysis of Wine.—W. Lenz.—A great number of processes for the determination of various constituents and possible impurities. It is remarked that blood decolourised by means of sulphurous acid displays no absorption-bands when examined with the spectroscope.

The Examination of Honey.—Attention is called to the fact that bees convey into their cells not merely the nectar of flowers, but the so-called "honey-dew" from the leaves of plants. Honey containing such an admixture behaves as if adulterated with starch-sugar.

Examination of Fats.—R. Bensemann.—The author has investigated the melting points of fats, and tabulates his results.

The Quantitative Determination of the Cinchona Alkaloids.—Y. Shimoyama.—The author concludes that De Vrij's method for determining quinine in presence of other alkaloids is to be rejected. Hielbig's method for separating quinine from cinchonine is useless, but it may serve to separate quinine from mixtures containing no other alkaloids. He considers that all attempts to determine quinine in presence of cinchonidine as herapathite are in vain. The author's own method will be inserted in full.

Liquid Carbolic Acid.—This compound is supposed to be a mixture of crystalline phenol with 10 per cent of water. Sohlickum proposes to determine the proportion by mixing 10 c.c. of the sample with 10 c.c. of water at 20°, and, when the mixture has settled, reading off the volume of the lower stratum.

Determination of Nitrogen in Human Urine.—E. Pflüger and K. Bohland.—For the determination of the nitrogen the authors find their favourable opinion of the Kjeldahl process confirmed. They are of opinion that

the use of sodium sulphite, potassium iodide and iodate as indicator, is far preferable to litmus. They reject the use of starch entirely. They point out, as a possible source of error, the presence of ammonia in commercial sulphuric acid.

The Determination of Sulphur in Proteine Compounds.—According to Hammarsten losses are often experienced in performing Löw's process. Löw replies that such losses occur only when the mixture is pressed closely into the platinum crucible instead of being permitted to lie more loosely.

Determination of Uric Acid.—Salkowski has improved upon his original process. In the measured sample he removes the phosphates with magnesia mixture, and then precipitates the uric acid with a solution of silver as a silver-magnesium double salt. On decomposing this precipitate with hydrogen sulphide, and concentrating the filtrate, which is acidulated with hydrochloric acid, the uric acid is obtained in a crystalline state.

Animal Gum in Urine.—H. A. Landwehr.—Animal gum is a normal constituent of human urine. The author mixes the urine with copper sulphate, and adds soda-lye in large excess. The blue flocks are filtered off, washed with water, dried, and dissolved in a minimum of hydrochloric acid. On adding 3 vols. of absolute alcohol, and heating to 60°, a fine precipitate appears, which is animal gum. Landwehr believes that Thudichum's cryptophanic acid and Béchamp's nephrozymase consist chiefly of this gum.

Behaviour of the Biliary Acids with Glue and Glue-Peptone.—According to F. Emich glykocholic acid precipitates neither glue nor glue-peptone from solution. But if to a solution of glue there is added taurocholic acid, or a taurocholate and hydrochloric acid in slight excess, the glue is separated out quantitatively.

Researches on the Number of Blood-Globules and on the Quantity of Hæmoglobin in Blood.—J. G. Otto.—The details of the author's researches are not given.

Albumenoids of Milk.—J. Sebelien.—There are at least two albumenoids present in milk along with caseine, lacto-globulin and lactalbumen.

Detection of Oxydimorphine.—W. Marme.—The author gives, in a series of tables, the behaviour of this alkaloid as compared with morphine, apomorphine, and codeine.

Equivalents of Carbon, Phosphorus, Tin, and Zinc.—J. D. Van der Plaats.—For carbon the author obtains values quite in accord with those of Stas and Dumas, and of Roscoe. For phosphorus he finds numbers ranging from 30·90 to 31·08. Tin gave values from 118·01 to 118·14, and zinc 65·14 to 65·21.

Monteur Scientifique, Quesneville.
Series 3, Vol. xv. December, 1885.

Method for Preventing Rabies after a Bite.—L. Pasteur.—A medical paper, read before the Academy of Sciences and the Academy of Medicines.

On Acridine.—M. Bernthsen.—Translated from *Liebig's Annalen.*

The Action of Diazo-Compounds on β-Naphthylamine.—F. A. Lawson.—The product is a red crystalline body, forming rhombic tablets insoluble in water, fusible at 102°-104°, and not decomposed on boiling with alcoholic potash. If boiled with dilute sulphuric acid (20 per cent) it loses nitrogen and is split up into phenol and β-naphthylamine.

On Crystalline Methyl-Violet.—A. W. Hofmann.—The author obtains this product by acting on dimethylaniline in presence of aluminium chloride, with chlorinised methyl-formic ether. Hexamethyl para rosaniline hydrochlorate is thus obtained in hexagonal crystals of a coppery lustre.

A New Class of Colouring Matters.—O. N. Witt.—On heating the amido-azotoluene derivative of paratoluidine with the hydrochlorates of the primary aromatic amines, there is a very complicated reaction which generates colouring matters.

On Indigotine Dicarbonic Acid.—W. Loew.—The author has prepared carboxylic derivatives corresponding to the sulphone derivatives of indigo.

On Bresiline.—MM. Buchka and Erck.—These chemists obtain pure bresiline by the following process:—They dissolve 10 parts of commercial bresiline in a little alcohol, and add to the solution 400 parts of ether. The ethereal solution is then mixed with five parts of strong nitric acid. The liquid is let stand for 36 hours, and is then exposed to spontaneous evaporation. The bresiline is deposited in the form of brilliant laminæ, which are washed with cold water until the acid reaction disappears and then with boiling alcohol. Oxidising agents entirely destroy bresiline. Nitrous acid converts bresiline in acetic solution into tri-nitro-resorcine, though the greater part of the product is destroyed.

Patents on Colouring Matters Obtained at Berlin.—These patents relate to the preparation of tetraiodopyrrol, to the preparation of a colouring matter and a mordant with catechu, to quinoleic compounds obtained by heating amidic aromatic substances with mixtures of aldehyds and acetones, to violet and blue azo-colours resulting from the reaction of tetrazoditolyl or its salts upon the naphthols or their sulphonic acids; the preparation of substituted benzoic aldehyds, and to an improvement in the preparation of β-naphthol γ-sulphonic acid.

On Cochineal and Carmine.—C. Liebermann.—Carmine does not, as stated in the text-books, consist of carminic acid "combined with small quantities of alumina and lime," for the quantities are not small. It is a nitrogenous body containing 3·7 per cent of nitrogen in the dry substance. The best samples sold as "carminnaccarate" contain—Water, 17 per ct.; proteic matter, 20; ash, 7; colouring matter, 56; wax, traces. The ash contains 43·09 per cent of alumina, 44·85 per cent of lime, besides soda, potash, and phosphoric acid to the amount of about 3 per cent each. In the ammoniacal solution of carmine the alumina and the lime are completely masked, so that ammonium oxalate determines no precipitate. Carmine offers a remarkable analogy to the aluminic lake of alizarin or purpurin, into which lime and an organic compound—emulsive oil—enter also as components.

The Wax and the Fatty Matters of Cochineal.—C. Liebermann.—The wax in question, coccerine, is distinguished from all known waxes by its properties and its elevated melting-point.

The Manufacture of Glucose.—From the CHEMICAL NEWS.

Patents on the Chemical Arts taken out in France.

Selection of Patents Connected with the Chemical Arts.—These two lists both contain French patents for October last.

Electric Furnace for the Reduction of Refractory Minerals.—T. S. Hunt.—From the CHEMICAL NEWS.

The Germs of Yeast in Bottled Beers.—Taken from the *Journal des Brasseurs*, but originally a translation from the *National Bottlers' Gazette.*

On the Action of Soluble Phosphates on the Rootlets of Plants.—Jules Joffre.—The author shows that, though strong solutions of soluble phosphates injure the rootlets of plants, weak solutions, such as alone occur in agricultural practice, have no such action.

Manufacture of Liqueurs and the Crystallisation of Sugar.—Julius Krüger.—In this paper, which is credited to the *Revue de la Distillerie*, but which seems to

be of German origin, the author points out the objections to the use of glucose syrups as a substitute for, or a sophistication of, cane-sugar.

Prizes offered by the Swiss Society of Chemical Industry.—A prize of 1200 francs is offered for an improved apparatus for determining the value of fuel; preferably it should be capable of operating upon several kilos of the combustible. A prize of 300 francs is offered for an improved arrangement of bleach and dye-works, showing methods of lighting, ventilation, and heating. Arrangements are desired for preventing internal fog in winter, the condensation of water on the inside of the roof, and the rusting of the iron-work. Memoirs, written in French or German, to be sent to M. Jenny Studer, of Glaris, up to December 31st. 1886, each marked with a device or motto, and accompanied by a sealed envelope containing name and address of writer.

Justus Liebig's Annalen der Chemie,
Vol. ccxxx., Part 2.

Studies on the Methylene Blue Group.—August Bernthsen. (Continuation).—This bulky memoir does not admit of useful abstraction.

On Nitrogen Iodide.—F. Raschig.—Several distinct, though unstable, compounds have been included under the name nitrogen iodide. The existence of a tri-iodamine has been definitely established, but mono-iodamine is still doubtful.

Behaviour of certain Organic Nitrogen Iodides.—F. Raschig. The author describes di-iodmethylamine and ioddimethylamine and the corresponding ethyl compounds.

On the Terpenes and the Ethereal Oils.—O. Wallach. (Third Treatise.)—The author here discusses borneol, camphene, the so-called "borneen," sylvestreene, Russian oil of turpentine, terpinol, terpinene, terpinolene, and terpineol. His principal results are that borneol, melting at 206°, behaves in general like a saturated secondary alcohol, but it forms with bromine and with halogenous hydracids instable double compounds. Camphene is formed directly from borneol by the action of dehydrating agents. Borneen is a mere mixture of the decomposition products of camphene. The Swedish and the Russian oils of turpentine are identical in composition. They consist essentially of a mixture of pinene, sylvestrene, and dipentene, probably along with terpinene. The characteristic ingredients of both these oils is sylvestrene. Terpinol, as described by Wiggers and List, does not exist. Terpineol is a non-saturated monatomic alcohol. Terpinene has the same melting-point as dipentene, but yields, on bromination, liquid products. The author arranges the terpenes which he has examined in two parallel series, whose corresponding members agree in their boiling points. I. Pinene, sylvestrene, terpinene. II. Camphene, limonene, dipentene, terpinolene.

Journal de Pharmacie et de Chemie.
Series 5, Vol. xii., No. 10, November 15, 1885.

Method of Preventing Rabies after a Bite.—L. Pasteur.—This paper has no chemical bearings.

Apparatus for the Rapid Determination of Dry Residues.—M. Yvon. This apparatus, which combines the action of heat and of a vacuum with the absorbent power of sulphuric acid, cannot be intelligibly described without the accompanying illustration.

On the Toxic Product extracted from pure Cultivations of the Comma Bacillus, and its Comparison with that extracted from the Bodies of Cholera Patients.—W. Nicati and M. Rietsch.—The authors have obtained a ptomaine, which is apparently due to the cholera-bacillus, and which is found to produce, when injected into the bodies of animals, all the symptoms of cholera.

Note on the Chemical Verification of the Purity of Butters.—A. Andouard.—The author, whilst recognising the value of the process of MM. Hehner and Angell—determination of the fixed and insoluble fatty acids, and that of Lechartier—the determination of the soluble and valuable fatty acids—considers that the interpretation of the results is sometimes difficult on account of the uncertainty of the limits presented by pure butters from different localities. He finds that pure butters from Bretagne may contain more than 89 per cent of pure fixed fatty acids.

Hopeine.—This compound is a narcotic alkaloid extracted from the hop. It forms white crystalline needles, very sparingly soluble in water, but soluble in 50 parts of alcohol; 10 centigrammes would probably be a fatal dose for an adult.

No. 11, December 1, 1885.

On Acid Magenta in Wines. — P. Cazeneuve. — Nine-tenths of the wines fraudulently coloured are got up with this product—the sulpho-conjugated compound of rosaniline. Ordinary magenta may be detected either with lead sub-acetate and amylic alcohol, or with ammonia and ether followed by an acid. The sulpho-conjugated compound cannot be thus discovered. Wines coloured with this compound show, if examined with the spectroscope, two bands, one towards the red and the other at the beginning of the blue of the spectrum. Both disappear if an alkali is added to the liquid. M. Bellier adds to the suspected sample an excess of coloured magnesia, and then there is a small quantity of a 2 per cent solution of mercuric acetate. If the wine is pure the filtrate is colourless, and is not reddened by acids. If acid magenta is present it is thus reddened. A still simpler method is to shake up 50 c.c. of the wine with 50 grms. of manganese peroxide. Natural wines and such as have been coloured with vegetable colours, with the azo-dyes and ordinary magenta, are rendered colourless, whilst the colour of acid magenta is not removed.

On the Determination of the Points of Fusion.—P. Chastaing. — This paper does not admit of useful abstraction.

Qualitative Detection of Nitrates and Chlorates.—M. Behal.—The author bases his method on the property of nascent hydrogen to convert the nitrates into ammonia, and the chlorates into chlorides.

Toxicity of the Oxides of Phosphorus.—M. Schultz.—The hypophosphites are not poisonous. The phosphites are violent poisons, acting on the nervous centres and the abdominal glands. The hypophosphates, meta- and pyrophosphates have a poisonous action on the stomach; the orthophosphate is well known to be harmless. Those phosphorus acids which contain an even number of atoms of oxygen are not poisonous.

MEETINGS FOR THE WEEK.

MONDAY, 11th.—London Institution, 5.
—— Medical, 8.30.

THE CHEMICAL NEWS.

Vol. LIII. No. 1364.

COMMERCIAL TREATMENT OF ROMAN ALUNITE.*

By M. P. GUYOT.

The *Chemische Industrie*, No. 2, 1885, p. 50 (*Ber. Chem. Ges.*, vol. xvii., p. 2888; *Chemiker Zeitung*, vol. ix., No. 20, 1885, p. 361) has analysed some work of M. C. Schwartz on the calcination of Roman alunite, and the determination of the best strength of acid to use to obtain complete solution of the alumina and the potash. The author arrives at this conclusion—that calcination at 500° is preferable to that obtained at lower temperatures, and that acid at 33° Baumé dissolves the alumina and the potash better than acid at a higher degree of concentration.

The work of M. Schwartz only confirms the observations that we published some years ago (*Comptes Rendus*, vol. xcv., p. 693, 1001, and *Journ. de Pharm. et de Chim.*, 5th series, vol. vi., p. 337) at the completion of some commercial trials that we made in 1879 and 1880.

Alunite contains two products important in the manufacture of alum:—

1. Alum and sulphate of alumina (basic).
2. Free alumina.

The heat of the calcination acts first of all on the alumina, which loses all its water of combination; it thus becomes soluble in acids, while the basic salts require a higher temperature before becoming soluble in their turn. Furthermore, alumina submitted to a high temperature becomes insoluble in acids; therefore its solubility in these agents depends on the temperature it has been submitted to. It follows that if, on the one hand, we wish to obtain all the free alumina soluble in acids (which we can do with a moderate temperature) we have, on the other hand, a loss of natural alum in the insoluble state. It is necessary therefore, for calcination, to be guided by the experience which, according to analysis, gives the least loss of these products, as well as causing the least expense for calcination.

To find the most favourable temperature we made four experiments, in each case using the crude powder finely sifted, and of the following composition:—

Potassic sulphate	14·00
Aluminic sulphate combined with potassic sulphate	26·55
Free aluminic sulphate	6·56
Free anhydrous alumina	18·58
Water	11·90
Ferric peroxide	0·80
Siliceous residue	21·61
	100·00

The following table gives the analytical results of minerals calcined at different temperatures. (See next col.)

By inspecting this table it is easy to see that a calcination at 800°, or between 800° and 900°, gives very superior results to those obtained at lower temperatures,

	Experiments on 100 tons calcined in quantities of 625 kilos			
Temperature	600°	700°	800°	900°
Duration of calcination	5½ h.	3 h.	3 h.	1¾ h.
Loss in calcination, per cent	16·87	16·82	19·06	16·96
Percentage composition of the calcined mass:—				
1. Soluble potassic sulphate	7·64	8·50	15·00	12·0
2. Anhydrous sulphuric acid from the soluble aluminic sulphate	8·00	7·92	11·10	11·62
3. Anhydrous alumina from the *quantum* of soluble potassic sulphate	4·49	4·99	8·85	7·04
4. Anhydrous alumina in excess, soluble in acids	23·00	20·16	24·00	23·00
5. Insoluble potass. sulphate	7·56	7·02	1·80	4·28
6. Insoluble alumin. sulphate	14·84	14·99	3·52	8·30
7. Alumina in excess, insoluble in acids	—	3·60	—	—
8. Ferric peroxide	1·00	1·00	1·00	1·00
9. Siliceous residue	33·47	31·82	34·73	32·76
	100·00	100 00	100·00	100·00

even when this roasting is prolonged by more than two-thirds.

The final yield in alum varies according to the two following causes:—

1. Concentration of the acid employed.
2. Quantity of acid used.

In rapid work, to dissolve in a commercial manner all the anhydrous alumina of the calcined mineral, and to prevent in the clay ovens the formation of basic aluminic sulphate, it is indispensable to carry on the operation with a large excess of sulphuric acid over a quantity theoretically required. To determine what this excess should be we made several experiments with a mineral requiring 800 kilos. of acid, at 52° to 53° Baumé, per ton, and we successively employed for 8000 kilos. of powder, 7, 8, 8·8, and 9·8 tons of acid at 52°. All the trials were conducted in the following manner:—The acid having been poured into the clay oven, and reduced to 30° Baumé, the attack was commenced between 80 and 90° C. The calcined powder was added to the acid by several instalments, the liquid mass being stirred so that the reaction might proceed regularly. After the addition of all the powder two hours are allowed to complete the reaction; then, after concentrating the liquid by bringing it to 38° Baumé, the potassic sulphate is added. This operation, from the commencement up to the complete solution of the sulphate, lasts about ten hours. It is then left thirteen hours to settle, when the clear liquid is drawn off. This liquid is about 41° to 42° Baumé, a point which must not be exceeded, or we should not be able to clarify the three-quarters of the liquid, the last quarter only remaining muddy.

The muddy portion is reduced to 24° Baumé by the addition of mother-liquor; after well stirring it is again left. When the liquid is clear it is drawn off into the vat where the first lot is. After one day settling the matter becomes quite cool; the deposited alum is taken out and refined.

The operation at 24° Baumé has still left a thick portion and a siliceous residue. The liquid is drawn off into a brick tank, where the alum is allowed to crystallise. A further quantity is obtained by washing the residue.

For the four roastings which served for our experiments we used calcined powder of uniform richness.

The crude mineral contained 12·5 per cent of potassic sulphate; the loss by calcination was 22 per cent, of which 9·88 per cent was sulphuric acid.

* Communicated by the Author, with the following letter:—

"Monsieur,

"L'intéressante note de M. Spencer Umfreville Fickering, sur le sulfate d'alumine que vous avez publiée en 1882 dans le Chemical News, m'engage à vous soumettre l'étude que je viens de terminer sur la fabrication de l'alun au moyen de l'alunite de la Tolfa. Voulez vous lui accorder l'hospitalité des colonnes de votre journal?

"P. Guyot, Chimiste;

"Nancy, 17 9bre, 1885." Réd. du Repertoire de Pharmacie.

The calcined mineral contained:—

1. Soluble potassic sulphate	13·93
2. Anhydrous sulphuric acid from the soluble aluminic sulphate	9·20
3. Anhydrous alumina combined with sulphuric acid	3·94
4. Free anhydrous alumina	23·06
5. Ferric peroxide	0·60
6. Non-calcined mineral	8·23
7. Siliceous residue	41·04
	100·00

The following are the results of the trials:—

Calcined mineral, 8 tons; sulphate 2·7 tons.

	Sulphuric acid 52° Baumé used.			
	7000	8000	8800	9800
Commercial alum (less 2 % moisture)	2·632	5·285	9·552	10·670

Commercial alum (less 15 % for impurities and loss in refining)	3·523	2·348	4·304	4·483
Alum obtained from the muddy liquid of the 2nd operation (less 18 % for impurities and loss).. ..	0·779	0·820	1·132	1·121
Alum from the mother-liquor from the vat (less 15 % for impurities and loss).. ..	0·449	0·447	0·450	0·449
Total available alum..	8·030	10·057	17·562	18·963
Quantity obtained per ton of calcined ore	1·003	1·257	2·195	2·3704

Analysis of the residue:—

	Per cent of Calcined Ore. Operation at			
	7000	8000	8800	9800
Anhydrous alumina not attacked	15	10	5	3
Insoluble potassic sulphate	2·35	2·20	2	2·01

In the operations with 7 and 8 tons of acid the alumina is nearly all found to be in the state of basic sulphate. In each trial mother-liquors of known richness were used, and their value was taken into account in the calculations.

It must be noted that the excess of acid used in attacking the ore eventually remains in the mother-liquor. These liquors being used over again are beneficial to the following lots.

If, however, instead of an ore containing 12½ per cent of potassic sulphate one had been used containing—as is sometimes the case—14 per cent, the price would be less, the expense being the same for treating rich or poor ores.

From the two preceding tables we see that the yield of alum obtained in the four lots is far from what it theoretically should be, especially in those cases where we have used a small quantity of acid, although more than theoretically necessary. The calcination at 800° or 900° C., besides the anhydrous alum, still contains some anhydrous alumina which resists the action of the acid when it has been recently used. The anhydrous alum is insoluble in water if it has not undergone previous hydration, which is generally slow in its action: it is for this reason that the residues containing potassic sulphate, which in spite of ten hours' maceration remain unhydrated, are insoluble.

Part of the alumina becomes at a high temperature insoluble in acids, which is only overcome by prolonged maceration in acidulated water. In ten hours all the alumina is not entirely dissolved; therefore the residue always contains more or less according to the excess of acid used, this latter favouring the modification or transformation of the alumina from the insoluble to the soluble state.

However, the excess of acid to be employed has a limit, which should be determined according to the richness of the ore. From fresh trials made with a roasted ore obtained from the crude ore, containing 14·5 per cent of potassic sulphate, we have decided that the excess of acid should not be more than 9800 for 12·5 of potassic sulphate. The results are satisfactory, and the settling rapid with a quantity proportionably less, which tends to prove that the potassic bisulphate formed aids the solution. Having to try a rich ore, and basing our plans on the formula 9800, which gave the best results with the poor powder, we should have to use 15·12 tons of acid at 52° or 53° Baumé; now, having used only 12·5 tons of acid for the attack, we obtain a very good result, 2·37 times the weight of the powder used. It should be noted that for this rich ore the theoretical quantity is 10·664 tons of acid at 52° Baumé for 8 tons of calcined ore.

At the moment of roasting the composition of the mass should be found, and the quantity of acid to be used decided on, according to its richness in alkaline sulphate, keeping account of the quantity of acids in the mother-liquors which will be used during the working up of the material.

The mother-liquors, which gradually become very impure, at length affect the purity of the alum; they represent a great loss of acid, which could be prevented by a prolonged maceration of the ore. It is this which has given rise to the operation of *Camelotte** that we have described (*Comptes Rendus*, vol. xcv.); the maceration in an acid liquid causes the necessity of expense in labour, of time, plant, &c. Furthermore, when it is necessary to change the macerated and moistened ore to the attacking ovens, we experience difficulties which make us give up this method of working, for we must not think of leaving the clay ovens quiet for several days, or even a week, while performing the maceration, for the sediment would solidify at the bottom and close up the openings of the steam-pipes, and cause explosive projections on resuming the operation.

To conclude, the best process consists in recovering the acid by the preparation of secondary products, impure it is true, but which might be found useful in certain industries.

CHEMICAL AND MICROSCOPICAL STUDIES ON THE ACTION OF SALICYLIC ACID ON FERMENTS.†

By Dr. A. B. GRIFFITHS, F.R.S.E., F.C.S. (Lond. and Paris).
Lecturer on Chemistry, Technical School, Manchester;
Examiner in Chemistry, Blairlodge School, Polmont, N.B., &c.

My attention has been occupied with a chemical and microscopical study on the action of various compounds on the lower forms of plant life. I have already presented to the Chemical Society of London a paper on the action of a solution of ferrous sulphate on certain parasitic diseases which attack our crops. I wish here to detail some studies on the action of salicylic acid on certain ferments (organised and unorganised). A solution of salicylic acid was prepared containing 0·2 grm. of the acid in 1000 c.c. of water. A drop of yeast was placed on a slide under the microscope, and then a few drops of the above salicylic acid solution was run in between the slide and cover-slip, when I found that it had no action on the true alcoholic ferment; for I was unable to stain the protoplasm of the cells with a dilute solution of eosin, showing that the protoplasm was not dead. But when I operated in a like manner on certain other organised ferments,—viz., on Mycoderma aceti, Bacterium lactis, and the Butyric

* *Répert. de Pharm.*, vol. xli., No. 9, p. 406.

† A Paper read before the Royal Society of Edinburgh, Jan. 4, 1886.

bacillus—it was very different. On running in the same salicylic acid solution upon slides containing these various ferments they were quickly destroyed. What was observed under the highest powers of the microscope was that the salicylic acid acts chemically upon the cellulose or the *form* of cellulose making the external walls of these lowly organisms. It was evident that the acid dissolved the cellulose wall, and in some cases I could see that the cellulose wall had been perforated by the acid solution.

Beyond these facts, I have found that the above-named aqueous solution of salicylic acid also prevents the chemical action of hydration by means of the soluble zymases. If yeast is added to a solution of cane-sugar, and to this solution the salicylic acid solution is added, no decomposition, according to the following equation, takes place :—

$$C_{12}H_{22}O_{11} + H_2O = C_6H_{12}O_6 + C_6H_{12}O_6.$$

That is, the salicylic acid has acted upon the soluble zymase which is secreted by the Torula cerevisiæ. Hence no fermentation takes place. I allowed the above to stand for two or three days at a temperature most suitable to engender alcoholic fermentation (about 80° F.), and then tested for glucose sugars by means of Fehling's solution without any result. I also tried the action of the salicylic acid solution upon a solution of starch which had previously been "inoculated" with a small quantity of saliva. After standing several days I could not find the smallest trace of glucose sugar. From this, salicylic acid acts upon the soluble ferment (ptyalin) contained in saliva, preventing the hydrating action upon the amyloses.

Then, again, I have found that the above solution of salicylic acid acts chemically upon the cellulose walls of *dead* torulæ, destroying them in a similar manner to the organised ferments already described at the commencement of this paper, but it (the acid) has *no* action on the *living* torula. This shows that a chemical change must have taken place in the molecular structure of the cellulose wall of the cell after death of the organism.

It is a well-known fact that in every brewery the yeast becomes deteriorated at certain times, and hence the beer brewed by such yeast is not so good as formerly. This is due to "disease ferments" in the yeast (the organisms I have alluded to in the early part of this paper). The common remedy is for the brewer to change his yeast. But I have found that this is not essential if the brewer waters the "diseased yeast" with the solution of salicylic acid; the "disease ferments" are all destroyed; the yeast is not acted upon by this solution. Yet at the same time the yeast so treated is not so active in its decomposition of a glucose solution into alcohol. This yeast can be revivified by an aqueous solution containing 0·25 grm. of potassium nitrate and 0·2 grm. of sodium phosphate in 2000 c.c. of water. In fact, the torula appears to decompose a much larger quantity of sugar (in wort) into alcohol in a given time after the above salts have been added to 2 litres of wort than when the wort is not so treated. It appears that the torula lives its life-history to a certain extent by extracting the potash and phosphoric acid from these mineral substances, which come into the wort from the barley and hops. Mitscherlich long ago showed that the ash of yeast gave no less than 53 to 59 per cent of phosphoric acid, and from 28 to 39 per cent of potash. Hence it may be that a larger amount of alcohol would be produced in beers by the addition of small quantities of the above substances to the wort.

From the above investigation the following conclusions are to be drawn :—

(1.) That a certain solution of salicylic acid has no action on the living torula, but dissolves it when dead, showing that some chemical change (post-mortem) has taken place in the cellulose of the cell-wall.

(2.) That the solution of salicylic acid destroys "disease ferments" by acting upon the cell-wall, showing that their cellulose most probably differs from the cellulose of the Torula cerevisiæ.

(3.) That the solution of salicylic acid prevents the hydrating action of the various soluble zymases.

(4.) A solution of sodium phosphate and potassium nitrate revivifies exhausted yeast, and even increases the yield of alcohol in saccharine solutions.

(5.) Salicylic acid acts as an antiseptic agent of great value, because it acts directly on the disease ferments in beers, and not upon the true alcoholic ferment.

(6.) Salicylic acid is not a poison in quantities far exceeding the amount in the solution given in this paper. The acid is largely used in medicine in both France and Germany.

For those interested in the application of this acid in medicine I refer them to the following memoirs :—

ON A

METHOD OF ANALYSIS APPLICABLE TO MIXTURES OF HYDROCARBONS OF THE AROMATIC SERIES.

By C. FRIEDEL and J. M. CRAFTS.

There exist in the aromatic series four isomeric bodies answering to the formula C_8H_{10}: ethyl-benzene and the three xylenes. All four may originate in the decomposing action of aluminium chloride heated with hydrocarbons. The formation of ethylene in this reaction is not indicated by the escape of this gas, but by the presence of ethyl-benzine and ethyl-toluene among the products. Consequently, in the product boiling at 138°, we have to search for ethyl-benzine mixed with the xylenes.

The question is already solved for cases where toluene is heated to about 200° with aluminium chloride in a closed vessel. Under such circumstances there are obtained very considerable quantities of the ethylated benzines; but at a lower temperature the decomposition of the toluene is much less complete, and there is found only a small proportion of ethyl-benzine mixed with the xylenes, and to detect its presence a new analytical process is required. The best methods of separation hitherto employed are based upon Jacobsen's researches on the sulpho-conjugated acids. But this process, which works by means of fractionated crystallisation, is difficult to use for the analysis of a limited quantity of matter. The old methods for the oxidation of the hydrocarbons give characteristic products, but always with great losses of material, and as the hydrocarbons are unequally burnt by the oxidisers, we cannot judge of the relative proportion of the hydrocarbons contained in a mixture by the quantity of the acids obtained.

By the method which the authors propose the analysis may be made on a few decigrms. of material, but when ethyl-benzine is present it is preferable to employ a larger quantity, up to 5 grms.

Dry bromine mixed with 1 per cent of iodine converts the three xylenes exactly into tetra-bromides, whilst ethyl-benzine forms a dibromated substitution-product of more or less definite composition, but capable of being converted by the addition of bromine in presence of aluminium bromide or chloride into penta-bromated ethyl-benzine. This compounds melts at 141·5°: it crystallises in fine clinorhombic prisms, and distils with a considerable

decomposition at the ordinary atmospheric pressure, but at the pressure of 0·16 metre of mercury it can be distilled without decomposition. It is soluble in 11 parts of petroleum ether at 20°, and the bibromic product formed by the action of iodised bromine is miscible almost in any proportion with petroleum ether. The tetrabromised xylenes are much less soluble, requiring about 200 parts of petroleum ether. They are separated from ethyl-benzine as follows:—

To the mixture of hydrocarbons we add about ten times their weight of bromine containing 1 per cent of iodine, and the whole is allowed to stand for ten hours at the ordinary temperature. The excess of bromine is removed with a solution of potassa, the bromised product is dried and washed with petroleum ether in successive portions until the product extracted has a melting-point higher than 240°. The petroleum ether is evaporated to incipient crystallisation. We may even continue the evaporation as long as the tetrabromo-xylenes separated have an elevated melting-point. The small quantity of these bodies remaining in the liquid (the weight of which is ascertained) may be calculated from their solubility as given above.

The ethyl-benzine is then determined in a definite state of combination. After having evaporated the solution and driven off the petroleum ether, we mix the partially bromated product with 4 or 5 parts of bromine, which dissolves it without chemical action. On adding aluminium bromide or chloride hydrobromic acid is evolved. After some hours all the hydrogen of the central chain is replaced by bromine, whilst the ethyl-group remains intact. It is purified by a washing in potassa, crystallised out of benzine, and the ethylene pentabromide is weighed. A correction must be made for the small quantity of xylene tetrabromide which remains mixed with the ethyl-benzine. A determination of bromine serves to check the results, and to calculate the proportion of ethyl-benzine pentabromide in the substance weighed.—*Comptes Rendus*, ci., p. 1218.

CONTRIBUTIONS TO THE KNOWLEDGE OF SAMARIUM.*

By P. T. CLEVE.

The following is a *resumé* of my researches on the compounds of samarium. I had also intended to prepare and examine the metal, but the quantity of pure oxide of samarium at my disposal was not sufficient. On completing the separation of the oxides, which accompany the oxide of samarium, I expect to obtain a considerable additional quantity of the latter.

I have endeavoured to determine the specific gravities of the compounds of samarium, wherever the properties of the substances rendered an accurate determination possible. The determinations were all made in a perfectly uniform manner, viz., by weighing in benzol, care being taken in each case to determine the specific gravity of the benzol and of the substance at the same temperature. Every determination was carefully made, and I believe, therefore, that the accuracy of the results may be relied upon.

In the case, however, of certain anhydrous and very hygroscopic salts, obtained by heating the crystallised salts, great accuracy could not be attained.

In carrying out these researches I have been assisted by L. I. Eriksson, who made several of the analyses and some of the specific gravity determinations, for which I gladly take this opportunity of thanking him.

The crystalline forms of several of the salts of samarium have been determined by H. Sjögren, who will publish a more complete account of his researches later on.

* Presented to the Royal Society of Sciences of Upsala, Feb. 13, 1885.

In order to make this paper a complete monograph, I have included in it the most important facts contained in a paper on samarium published by me some time ago.*

History.

The first indications of the existence of samarium date back to the year 1878, when Delafontaine,† in examining impure didymia, extracted from samarskite, observed some new absorption-bands which he ascribed to a new metal, having an atomic weight of 106, assuming the oxide to have the formula RO, or 159 if R_2O_3 be the correct formula. He named the new metal decipium.

Some time later Lecoq de Boisbaudran‡ found also in samarskite an oxide, the solutions of which were characterised by a peculiar absorption and emission spectrum. He succeeded in separating this oxide from didymia by means of repeated fractional precipitations of the mixed nitrates by dilute ammonia. He called the metallic radical samarium. In 1880 Delafontaine§ published some researches on the compounds of decipium, the atomic weight of which he now found to be 114 or 171, according as the formula of the oxide be taken as DpO or Dp_2O_3. He found the sulphate to be much less soluble than the sulphate of didymium. The salts were colourless. Shortly after this Marignac‖ published a paper on the samarskite earths. By taking advantage of the different solubilities of the sulphates in a saturated solution of potassium sulphate he succeeded in separating two oxides, which he designated provisionally as Yα and Yβ. The atomic weight of the metallic radical of Yβ was 99·6 or 149·4, according to the formula assumed for the oxide.

The salts were yellow, and gave the absorption-spectrum first observed by Delafontaine, and more accurately described by Lecoq de Boisbaudran. The other oxide, Yα, obtained by Marignac, was white, and gave colourless salts having no absorption-spectrum. The sulphate formed with potassium sulphate a double salt soluble in a saturated solution of potassium sulphate, a quantity of this double salt corresponding to 1 grm. of the oxide dissolving in 100 to 150 c c. of the potassium sulphate solution. The corresponding double sulphate of Yβ was much less soluble, while that of the terbia was more soluble. The atomic weight of the metallic radical of Yα was estimated to be as a minimum 104·5 (or 156·75).

The identity of the absorption-bands leads to the conclusion that decipium, samarium, and Yβ all three contained the same element. But the atomic weights as determined by Delafontaine and by Marignac differed greatly.

Later on Delafontaine¶ admitted that his original decipia could be split up into two different oxides, one with an absorption-spectrum and one without. For the element in the former he adopts the name samarium, reserving the name decipium for the element in the latter. The respective atomic weights were 101 (or 151·5) and 111·3 (or 167). The Yα of Marignac he regards as a mixture of terbia and decipia, but as terbia is orange-coloured and Yα almost white this supposition seems to be inadmissible.

Separation.

There is no complete method of separating samaria from the other earths which accompany it. In order to remove the yttria earths advantage may be taken of the sparing solubility of the double sulphate of samarium and potassium in a saturated solution of potassium sulphate; but the most convenient method of separation from didymia is by fractional precipitations of dilute solutions of the nitrates by very dilute and cold ammonia. Samaria is precipitated first, but the operations must be repeated a

§ *Arch. des Sc. Phys et Nat.*, [3], iii., 250.
‖ *Ibid.*, [3], iii., 413.
¶ *Comptes Rendus*, xciii., 63.

great number of times. In order to obtain a pure oxide it is necessary to combine both methods. The sulphate of samarium is much less soluble than the sulphate of didymium, but as these salts are isomorphous no good separation can be founded upon this difference.

Mode of Occurrence.

Samarium has been found in samarskite, in gadolinite, in orthite, and in cerite, but there can be no doubt that this element will be found together with didymium in all minerals containing the latter metal. Nevertheless didymium seems always to occur in greater quantity.

Atomic Weight.

In my paper on samarium, which appeared in 1883, I published determinations of the atomic weight of samarium. By combining known quantities of samaria with sulphuric acid I obtained as a mean of six experiments the number 150·02 (maximum 150·12, minimum 149·94), assuming for the oxide the formula Sm_2O_3. This number agrees as well as could be desired with Marignac's determination of the atomic weight of $Y\beta$, viz., 149·4.

Spectrum of Samarium.

The chloride of samarium gives a spark-spectrum, composed of a great number of lines, for the most part of little intensity. They have been very carefully mapped by Professor Thalén,* who has registered 198 lines of samarium. A great number of them were formerly attributed to didymium. Many of the samarium lines were also observed by Roscoe and Schuster,† and by them attributed to terbium.

The absorption-spectrum of samarium has been described by Lecoq de Boisbaudran, by Soret,‡ and by Thalén. Their descriptions agree perfectly, and according to them the wave-lengths of the bands are:—

559—556	.. ..	yellow
497—500	.. ..	,,
486—472	(strong)	blue
466—460	(strong)	,,
445—437	(weak)	,,
419—415	.. ..	violet
409—401	(very intense)	,,

There are also, according to Soret, several absorption-bands in the ultra-violet part of the spectrum, the wave-lengths or which are—

375—373
364—360
344

Becquerel§ also discovered in the infra-red some absorption-bands with wave-lengths 1145 and 1040.

(To be continued).

PROCEEDINGS OF SOCIETIES.

MANCHESTER LITERARY AND PHILOSOPHICAL SOCIETY.

Ordinary Meeting, November 17, 1885.

Prof. W. C. WILLIAMSON, LL.D., F.R.S., President, in the chair.

"*On Some Recent Observations in Micro-Biology, and their bearing on the Evolution of Disease and the Sewage Question*," by F. J. FARADAY, F.L.S.

Nearly three years ago, in a letter which appeared in the *Manchester Guardian* of February 14, 1883, as a contribution to a controversy on the work of Pasteur and Koch, I concluded as follows:—"Pasteur is attenuating deadly parasites; before long some of his followers will evolve specific parasites from harmless saprophytes, and in the work of artificially evolving, some at least of the species, such gases as carbonic acid will render powerful assistance."

Replying to this letter, in the same journal, a London medical man spoke of the prediction as without foundation. I was the more surprised by such an expression of opinion from London, as the *Times*, commenting a few months previously on a paper on Koch's tubercle bacillus which I had read before the Biological Section of the British Association at Southampton, had been good enough to say that I had shown that empirical medicine had a scientific basis. In that paper I had argued that deprivation of free oxygen, or cultivation in gaseous mixtures from which the normal supply of free oxygen present in fresh air is absent, probably had an influence in converting otherwise harmless organisms into the parasitic bacilli of tuberculosis. I had submitted that the lungs of persons of hereditarily narrow-chested structure, or of weak breathing habit, or of persons spending much time in a vitiated atmosphere, engaged in dusty occupations, or suffering from bronchial catarrh, presented the requisite conditions of culture, assuming the presence of the germs of organisms which might otherwise discharge a useful function in the chemistry of life, possibly even in the chemical function of the lungs themselves. Dr. Angus Smith had also pointed out (*Rivers Pollution Report*, 1882) that the putrefying process, when carried on in open rivers, such as the Clyde, does not seem to produce any marked form of disease; whereas the gases escaping from covered sewers are apparently associated with specific zymotic maladies; and he had suggested that "we require to learn whether any of the germs of disease, or which germs, will live in an abundance of good air." Dr. Smith had hinted that possibly the relative harmlessness of putrefaction in open rivers was a consequence of the less concentration of the resultant gases, or the more thorough putrefaction, oxidation, and destruction of the organic substances. Looking at the question from the biological rather than from the chemical standpoint, it seemed to me that with all these ideas floating about, and especially after the discovery of Koch's tubercle bacillus, there was considerable foundation for the suggestion that possibly certain gases might have an influence in converting micro-saprophytes into micro-parasites, and it did not seem a long step from this primary thought to the idea that carbonic acid might be such a gas.

As the carbonic acid idea was, therefore, in the words of Touchstone, "all ill-favoured thing, but mine own," I may be permitted now to direct attention to a footnote appended to M. Pasteur's paper on a method of preventing hydrophobia after infection, read before the Paris Académie des Sciences on the 26th ult. M. Pasteur describes his method of attenuating the virus present in the marrow of rabbits which have died of rabies, by suspending portions of the marrow a few centimètres in length in dry air, the degree of attenuation being directly proportionate to the time of exposure, the dimensions of the fragment, and the temperature, the rabid property of the marrow being ultimately extinguished. The lower the temperature the more slow is the process of attenuation. By this process a graduated series of infective material, suitable for prophylactic inoculations, is obtained. M. Pasteur then says—"If the rabid marrow be kept from contact with the air, in carbonic acid gas, in a moist state, the virulence is maintained undiminished (at least for several months), provided that it is protected from foreign microbic alteration."

M. Pasteur has not yet discovered any microbe as peculiar to rabies, though the fact that a perfectly definite period is required for the development of the disease when the virus is introduced directly to the nerve centres,

* *Öfversigt af K. Sv. Vet. Akad. Förh.*, 1883, No. 7, 3.
† *Journ. Chem. Soc.*, xli., 1882, 283.
‡ *Arch. de Sc. Phys. et Nat.*, [3], iv., 261.
§ *Ann. de Chim. et de Phys.*, [5], xxx. 5.

which appear to constitute its appropriate *nidus*, is suggestive of the existence or evolution of a specific microbe. It is also as yet a mystery as to how, in the case of an ordinary bite, the affection is conveyed to the nerve centres, whether, by transmission through the blood, the specific infection ultimately obtains a lodgment in the ganglia suitable for its incubation, or whether an influence is conveyed through the nerves which sets up corresponding changes in Béchamp's hypothetical micro-zymes in the nerve centres, thus evolving from healthy material morbid organisms whose action is identical with that of the disturbing causes.

In this latter supposition we seem to see something analogous to induced electricity, and I may add that, throughout the whole of the phenomena of zymotic disease, there is a suggestion of action with corresponding and intensifying reaction. Given a micro-organism producing a certain effect upon an environment, that effect, in the absence of disturbing influences, seems to react upon the organism itself and increase its ability to reproduce the specific effect. To make my meaning clearer, let us suppose microbia present in a confined sewer. Their action results in the production of certain gases, and the presence of those gases again intensifies the action of the microbia. Or, to put another supposition, certain microbia present, say, in the peripheral regions of the nervous system, produce a given effect through the nerves upon the nerve centres, and that effect re-developes, from the "organic molecules" of the nerve centres, organisms or ferments capable of acting precisely as the original microbia acted. Such suppositions appear to offer explanations of the varying virulence of zymotic diseases, and of the discoveries by Pasteur and his disciples relating to the attenuation or intensifying of microbia. They may also provide the key to the mystery of protective inoculations. For the mild vaccine calls into existence a certain resisting power which appears to be intensified by the consequences of its own action.

Leaving such speculations on one side, however, for the present, what I wish now to point out is that in Pasteur's latest experiments we appear to have another illustration of the hygienic value of fresh air, and a confirmation of the suggestion that carbonic acid is a gas capable of at least preserving zymotic disease. May we not, hypothetically, generalise the idea, and carry it a little further, by saying not only that fresh air favours saprophytic life, while foul gases favour parasitic life, but that foul gases evolve parasitic from saprophytic life. It is a remarkable fact that no genuine pathogenic microbia have ever been obtained from collections made from the atmosphere. Dr. Miquel has made a vast number of experiments in the cultivation of atmospheric germs, only to arrive at the conclusion that pathogenic microbia "appear to be banished from the air." I venture to submit, however, that this does not imply that infection may not be communicated through the atmosphere. Attention has been called to the fact that epidemics often appear to follow heavy rains, and it has been suggested that the pathogenic microbia may be present in overflows of stagnant water, or may be washed into pools of water temporarily formed, so that, when these dry up, the germs are blown with the sediment into the atmosphere and inhaled, or deposited in milk or other beverages. As such conditions imply, however, not only the presence of abundance of fresh air, but also sunlight (to the hygienic action of which latter I am about to refer), the supposition is rather against the results of the experiments under consideration. If, however, we assume the presence of pathogenic germs in the foul atmosphere of ill-ventilated sewers, then heavy rains, or any other condition which diminishes the air space in the sewers, will force out more or less dense volumes, or gusts, of sewer gas, and the germs be conveyed directly to their new medium of culture, whether in the bodies of men or animals breathing such gases, or in the beverage which they infect; and they will be protected during their passage from the attenuating influence of fresh air by the appropriate environment which transports them.

We come now to the influence of light and darkness on micro organisms, concerning which the results of some very interesting experiments, carried on independently by M. Duclaux and M. Arloing, have lately been made known. I proceed to consider these with the more pleasure, as they afford me an opportunity of again referring to one of those suggestive and thoughtful utterances which abound in the writings of our late revered member, Dr. Angus Smith. Referring to the fact that fevers have not been traced to open rivers, or to putrefaction in the open air, though they have been traced to decomposition taking place under cover, as in sewers, Dr. Smith observes, in a paper published in 1880, "The question arises, Is this owing to the concentration, or to the difference of decomposition in darkness, or to the better supply of oxygen? The effect of sunlight in warm countries does not allow us to suppose that the daylight always produces in vapours an innocent state, although it has a great effect in that direction when there is little water." M. Duclaux evaporated cultures of microbia in tubes, and then preserved the dried spores, carefully protected from external contamination, some being sheltered from the sunlight, and others being exposed to it, for various periods. The temperature of the sheltered tubes was regulated in all cases so as to be approximate to the maximum heat obtained from the sun by the exposed tubes, so that, excepting the light rays, the conditions in all cases were equal. On suitable infusions for culture being subsequently added, M. Duclaux found that the sheltered spores developed much more readily and abundantly than the exposed spores; the sunlit tubes proved, in fact, more or less sterile, according to the time of exposure, those which were exposed for the longest time entirely failing to give any evidence of microbe life. The fermentive action of the specific microbe experimented with, *Tyrothrix scaber*, is analogous to that of pathogenic microbia, as it destroys albumenoid matter; though it is important to bear in mind that it is what M. Pasteur calls an acrobic species. The dried spores of this microbe, when protected from the direct light rays of the sun, resisted the action of free air and a tropical temperature for three years, and germinated at the end of that period. A month's exposure to the sunlight, however, diminished the germinating power of the spores, and after two months' exposure 50 per cent of the tubes proved sterile. Similar experiments were tried with pathogenic micrococci. Cultures in broth preserved their vitality for at least twelve months, if sheltered from the direct rays of the sun. Exposure for forty days to the feeble and intermittent rays of the spring killed them; a fortnight's exposure to the July sun killed them; and exposure for a less number of days attenuated them, and deprived them of all power over the animals most susceptible to their influence. M. Arloing experimented with the anthrax bacillus, and found that sunlight diminished the vegetative power of the mycelium. Two hours' exposure to a July sun was sufficient to make a freshly infected broth sterile. Exposure for less than two hours retarded the vegetative power. When the spores are in process of actual development, however, the sunlight does not stop the growth; the mycelium grows and produces spores, the filaments break up, and the spores are set free. The process is, however, slower, and in this respect is analogous to the development as it takes place when the organism is cultivated in infusions which are little favourable to its growth. Sunlight, in fact, produces results analogous to those of culture in an unfavourable environment. When the mycelium has already developed spores in a darkened stove, exposure to sunlight for thirty hours stops vegetation. The power of growth is gradually weakened by exposure to sunlight, before it disappears altogether. If a drop of a solarised culture is used as seed for a fresh infusion, the vigour of the second generation is diminished in direct proportion to the length of time during which the parent culture has

been exposed to the solarising influence; the process of development is more and more protracted. Again, the diminution of vigour continues through successive generations. A third generation, the two preceding parent cultures of which have been exposed to the solarising influence, if itself exposed to sunlight, loses its vegetative power more rapidly than either of the two preceding generations; the attenuative effect is, in fact, accumulated. These phenomena are accompanied by an attenuation of virulence if the successive cultures are inoculated in animals, and eventually the organism actually becomes its own vaccine. In proportion to the duration of the solarising influence and its continuance through successive generations, a larger and larger quantity of the virus is necessary in order to successfully inoculate guinea-pigs with the specific disease, and the progress of the disease in the animal becomes slower and slower, until at length the influence is protective against the consequences of inoculation with an unsolarised or virulent culture.

It has been pointed out by a French writer that these experiments again confirm the doctrine enunciated by M. Paul Bert, that any influence which arrests the development of a virus converts it into a vaccine. In the paper on "Pasteur and the Germ Theory," which I read before the Society last year, I argued that the difference between a harmless saprophyte and a deadly parasite was a difference of vigour. If I may formulate the idea again, I would say that a saprophyte is an organism which is able to utilise for its own life the residual forces in matter in which the specific or co-ordinating vital force has been extinguished; while the parasite is an organism which, in consequence of a given process of culture, is enabled to overcome the still existing specific vital force of the living organism on which it preys, and to divert that force to its own development. In some mysterious way light and oxygen are favourable to the vigour of the higher organism, and inimical to the vigour of the lower organism. These conditions determine which of the two is to be the subordinate. I have been led to think that the life-history of microbia is analogous to the earliest stages of the life-history of the higher organisms in this respect, and I am arranging some experiments in order to test this idea, the results of which I hope to communicate to the Society in due time. The higher plants and animals begin their lives in darkness, and as they grow attain to light and fresh air; and then, if I may so express it, the higher life is progressively evolved.

It is well to point out distinctly that, as yet, however much reason there may be for believing that pathogenic microbia are really evolved from originally harmless ferments which have a great utility in the economy of the universe, and whose subordinate action may even be absolutely necessary for the existence of higher forms of life, such evolution has not yet been experimentally proved. Conversely, however, we have meanwhile definite evidence that fresh air and sunlight attenuate the virulence of pathogenic microbia. Even this partial knowledge is of great practical importance. It cannot be overlooked that vitiated air and darkness generally go together, and that, on the other hand, fresh air and sunlight are usually coexistent. Both the first-named conditions are necessarily associated in the covered sewer. Whether the covered sewer does or does not actually evolve the disease is at present a matter of speculation; but that the peculiar conditions of the covered sewer nurture and strengthen the diisease may be regarded as experimentally proved. Now I find that in connection with the Ship Canal project it is proposed to construct a covered sewer to receive all the sewage of this city. Of the conditions to be provided in this culvert we have as yet only the vaguest intimations. I confess that I, for one, look forward with the greatest anxiety to the prospect of such a huge drain, in which so vast a mass of organic matter will be allowed to putrefy in darkness and in the midst of an environment of foul gases. It seems to me that this Society will only be true to the traditions of its early history, and discharge a duty to the city to which it pertains, by watching this culvert scheme closely, and asking what provision is to be made for continuing the hygienic influences at present exercised on the Irwell by free oxygen and sunlight (so far as we possess either one or the other in this district), or what precautions are to be taken to counteract the vicious consequences of the absence of both?

The philosopher sees the same principles throughout nature; he learns to recognise that simplicity and harmony are the essential features of the constitution of the universe. The principles of one science reappear in all the others; the study of any branch of natural philosophy results in generalisations which elucidate the phenomena of other branches. And if he turns from the physical side of nature to its moral side the thinker finds the lessons of the one applicable to the other, and confirmed by its phenomena. The recognition of this truth does not seem to me to be beyond the scope of science. Microbia have a beneficent function; Pasteur's pupil, Duclaux, has shown us that the seeds of the higher plants will apparently not germinate if microbia are excluded from the soil; and Pasteur himself has suggested that probably no young animal would live if its food were absolutely deprived of organised ferments. The evidence tends to show us that if these same ferments are compelled to live in the environment provided by their individual action alone, they become the agents of deadly disease. If we turn to the other extreme of the biological chain we find that, with his physical nature deprived of sunlight and fresh air, and his mental nature compelled to feed upon its own vagaries, in short, with his mind darkened and unaërated, man himself becomes morbid and mischievous.

"*On the Flow of Gases.*" By Professor OSBORNE REYNOLDS, LL.D., F.R.S.

MICROSCOPICAL AND NATURAL HISTORY SECTION.

Ordinary Meeting, November 9, 1885.

Dr. ALCOCK, President of the Section, in the Chair.

Mr. ALFRED BROTHERS, F.R.A.S., read the following note on "*Microscopic Writing.*"

The Lord's Prayer has always been a favourite subject for testing the powers of minute caligraphy. To write the 227 letters within the space covered by the smallest coin is a feat of some difficulty, but that the same number of letters can be engraved on glass within a space so minute as to be almost invisible with the lowest power of the microscope, and the individual letters not defined clearly with an eighth object glass, may seem incredible. There is, however, in the possession of this Section a slide which contains the Lord's Prayer, written by W. Webb in 1863, within the space of the 405,000th part of an inch.

To find this minute speck requires the exercise of much patience, as it is not only necessary to have just the right kind of illumination, but the focus of the lens must be on the true surface of the glass on which the object is written. When once seen with a low power it is not difficult to find with the same power; but with the ⅛ inch and higher powers it is always a trial of patience even when the position of the object has been carefully registered with a lower power, and you are sure that the object is central in the field. Perhaps with the achromatic condenser some of the difficulty may be removed.

It will be remembered that about twenty years ago the late Mr. Rideout presented to the Section a machine for producing minute writing. The instrument was lent by Mr. Rideout to Mr. Dancer, by whom it was recently sent to the Society. It seemed to me that as this instrument was purchased by Mr. Rideout at the great Exhibition in 1862, it might be the same with which the wonderful piece of witing, or perhaps it should be called engraving,

referred to was executed. I therefore wrote to Mr. Dancer for information on this point. In reply he says:—"The microscopic writing on glass of the Lord's Prayer referred to in your letter was at one time in my possession, and was, I believe, presented by me to the Microscopical Section. It was obtained from Mr. Webb, and he was the same person who exhibited the microscopic writing machine at the great Exhibition of 1862. Mr. Webb died about ten or fifteen years ago, but I cannot give the exact date. I have a very strong impression that Mr. Rideout obtained the machine from him, which was sent by me to the Society. If able to find Mr. Rideout's letter it may confirm this." I have not received the letter, but as what Mr. Dancer says confirms the impression I have of what passed at the time, there can be little doubt that the instrument is the one used to produce the writing referred to.

Under the microscopes I have arranged two other slides of minute writing which have been lent to me by Mr. Armstrong. These are not *very* minute when compared with the one first referred to, and which I have placed under the third microscope where you will see the object with an eighth object glass. Even with this great amplification the words can scarcely be read, but it can be seen that only greater power is required to make the whole legible. It happens that the covering glass is very thick, so that powers higher than the eighth cannot be used. It will be noticed that the name *W. Webb*, 1863, is distinctly legible and very beautifully written.

Mr. Armstrong has given me some particulars of Webb's minute writing, from which it appears he was accustomed to write the Lord's Prayer in spaces of the 500th to the 10,000th of an inch, and, as we have seen, to the 405,000th, and the prices of these slides varied from 2s. 6d. to 70s.

CORRESPONDENCE.

THE INSTITUTE OF CHEMISTRY.

To the Editor of the Chemical News.

Sir,—I should feel much obliged if your correspondent "J. W.," who says that no notice was taken of his letter, would forward to me the date of his application, that I may enquire into the matter.—I am, &c.,

The Secretary of the Institute of Chemistry.

9, Adelphi Terrace, Strand, W.C.,
January 9, 1886.

THE INSTITUTE OF CHEMISTRY.

To the Editor of the Chemical News.

Sir,—A meeting of the members of the Institute of Chemistry who reside in Manchester and district was held last night at the rooms of the Chemical Club of Manchester, with a view of considering the very important questions in reference to the Institute which are at present being discussed in your journal, and with the intention of taking some combined action if considered advisable, so that the views of the majority of the members in the North of England, and generally perhaps in the provinces and in London, may be brought before the Council for its consideration.

The following resolutions were passed, and I was requested to forward them to you for publication:—

1. That this meeting deems it advisable that properly qualified chemists of good standing should at the present time be admitted to the Fellowship of the Institute without undergoing examination.
2. That new members so entering be not admitted on the same terms as the old members, but that some such difference be made as the following, viz.: —That the new members pay an entrance fee of, say, 5 guineas, and that they pay, say, 2 guineas subscription for the first five years, and afterwards that they pay a subscription of one guinea per annum. *The subscriptions of the whole of the present members being reduced to one guinea per annum from the beginning of this year;* and that the old members be at liberty, by the payment of, say, five or ten guineas, to purchase Life Fellowships.
3. That this meeting considers it desirable that the existing regulation of the Council, to the effect that a candidate for the Associateship must have studied three years in one of a limited number of specified colleges, should be extended, so as to allow such candidate to present himself for examination provided he has studied and practised for at least three years in the laboratory of a Fellow of the Institute in actual practice.
4. That the following members of the Institute, with power to add to their number, be constituted a Committee *pro tem.* to promote the acceptance of the resolutions passed at this meeting:—

John Angell.	Ferdinand Harter, Ph.D.
J. Carter Bell.	David Watson, D.Sc.
W. H. Darling.	Percy James Winser.
Charles Escourt.	

5. It was further resolved to request all the members of the Institute who are favourable to the views expressed at this meeting, or to any slight modifications of them, to communicate at once with me, that their names and any suggestions they have to make may be communicated to the next meeting of this committee.

—I am, &c.,

William Thomson,
Hon. Sec. pro tem.

Royal Institution Laboratory,
Manchester.

SCIENCE IN THE LAW-COURTS.

To the Editor of the Chemical News.

Sir,—The catechetical form of instruction—question and answer—is now justly scouted by educators and abandoned in our manuals and text-books. It is therefore very strange that the *Journal of Gas-Lighting* should consider the establishment where it still flourishes as "the supreme temple of arts and sciences" and the "greatest teaching university of the world."

Surely judge, jury, and spectators would more clearly understand expert evidence if read to them in the form of a continuous report, duly prepared beforehand, and where none of the "unwarranted assumptions, blunders, and slips of memory" which your contemporary mentions could have place. Such a report, drawn up by two or three disinterested men of science, and accepted as is the ruling of the judge on a point of law, would be much more satisfactory than our present system.—I am, &c.,

Experto Crede.

SCIENCE IN THE LAW-COURTS.

To the Editor of the Chemical News.

Sir,—Your view on the necessity for a reform in this subject is shared by Dr. C. G. Garrison, who, writing in the *Medical Bulletin*, contends that "as expert, the position of the physician is judicial, and he should be called by the Court, not by the litigants." By a parity of reasoning the same rule must apply to the chemist and the physicist, if their evidence is required as experts.

The *Medical Press and Circular* also supports the proposal of scientific assessors in Courts of Law.—I am, &c.,

R. B.

COMMERCIAL ANALYSES.

To the Editor of the Chemical News.

Sir,—Complaints have appeared from time to time in the columns of the Chemical News of discrepancies between the results of different chemists to whom samples of some commercial product had been submitted for examination. With your permission I should like to direct attention to the serious differences in determinations of oxide of iron and alumina which almost always occur when samples of phosphate are sent to two or more chemists for analysis. The following table records the experience recently obtained by a house of business with which the writer is connected. To avoid mentioning names I describe each chemist by a number, and may add that all are well-known members of the profession practising in London.

	I.	II.	III.	IV.	V.	VI.	VII.
Carolina Land—							
P_2O_5 = tribasic phosphate	58·42	58·25	57·68	—	—	—	—
Oxide of iron and alumina	3·30	6·06	4·34	—	—	—	—
Belgian—							
P_2O_5 = tribasic phosphate	—	—	49·60	49·34	—	50·06	—
Oxide of iron and alumina	—	—	7·14	4·47	—	4·03	—
Belgian—							
P_2O_5 = tribasic phosphate	—	—	46·06	—	46·50	—	—
Oxide of iron and alumina	—	—	14·57	—	10·30	—	—
Aruba—							
P_2O_5 = tribasic phosphate	—	—	76·30	—	—	—	79·02
Oxide of iron and alumina	—	—	4·28	—	—	—	3·50
Aruba—							
P_2O_5 = tribasic phosphate	—	—	77·64	—	—	—	79·31
Oxide of iron and alumina	—	—	5·52	—	—	—	3·75

In these cases the uniformity of the samples was beyond all question—they were in fact absolutely identical—and I can only explain the matter by supposing that the various chemists employ different methods of analysis. Can any of your readers offer suggestions which might lead to more concordant results being obtained? By so doing they will be conferring a great boon upon merchants and manufacturers, to whom these discrepancies are a continual source of annoyance and vexation.—I am, &c.,

X. Y. Z.

TURNIPS WITHOUT SULPHUR.

To the Editor of the Chemical News.

Sir,—In the Chemical News, vol. liii., p. 289, Mr. Thomas Jamieson reports that turnips grew well in soil containing no sulphur, and that "fully developed turnips gave on analysis no sulphur whatever."

I would like to inquire what they tasted like, and what would be the probable taste of mustard or horseradish thus grown? And also to ask if fertile seeds of such Cruciferæ as mustard, turnip, cabbage (all *Brassica*) have been obtained free from sulphur, or if Mr. Jamieson supposes that they can be?—I am, &c.,

S. A. N.

CHEMICAL NOTICES FROM FOREIGN SOURCES.

Note.—All degrees of temperature are Centigrade unless otherwise expressed.

Comptes Rendus Hebdomadaires des Séances, de l' Académie des Sciences. Vol. ci., No. 25, December 21, 1885.

This issue contains merely the account of the Annual Public Session held on Dec. 21, and the awards of the prizes which are in the gift of the Academy. The Bordin prize was assigned to M. Edlund for his reply to the question: "to find the origin of atmospheric electricity and the causes of the great development of electric phenomena in storm-clouds." The Jecker prize in chemistry has been divided between MM. Prunier, Silva, and G. Rousseau. The Lacaze prize in chemistry has been awarded to M. A. Ditte, of Rouen. The "grand prix" in the mathematical sciences proposed for 1886 is:—"to improve in some important point the theory of the application of electricity to the transmission of work."

No. 26, December 28, 1885.

Application of the Numerical Laws of Chemical Equilibria to the Dissociation of Chloral Hydrate.—H. Le Chatelier.—A mathematical paper not susceptible of useful abridgment.

Action of some Reducing Agents upon Vanadic Acid.—A. Ditte.—The author examines the action of hydrogen, sulphur, ammonium oxalate, arsenic, phosphorus, and sulphurous acid upon vanadic acid. By their means he obtains the following series of oxides, V_2O_9, V_2O_8, V_2O_7, and V_2O_6.

The Preparation and the Physical Properties of Phosphorus Pentafluoride.—H. Moissan.—The author maintains that the pentafluoride cannot be obtained in a state of purity by Thorpe's process. He prefers to pass an excess of gaseous phosphorus trifluoride into bromine at −15°. The result is a liquid phosphorus pentafluobromide which slowly decomposes, yielding solid phosphorus pentabromide and gaseous pentafluoride. This is an incombustible gas, of a pungent odour, fuming strongly in the air, and entirely soluble in water. Its density in three experiments was found to be 4·50, 4·49, and 4·48. At 16° and under a pressure of 46 atmospheres it becomes liquefied. At this temperature the liquid has no action upon silicates. If gently released from pressure there is formed in the tube a snow-like solid which quickly melts.

Combinations of Gold Trichloride with Sulphur and Selenium Tetrachlorides.—L. Lindet.—The double gold and sulphur perchloride forms fine yellow needles. It loses chlorine even at common temperatures, even if an attempt is made to dry it in a current of chlorine. It is hygroscopic and is decomposed by water, yielding brown liquids not yet studied. Gradually the gold is reduced and all the sulphur passes into the state of sulphuric acid. The corresponding selenium compound forms tabular crystals of a fine red, slightly inclining to orange. The author has not succeeded in combining gold chloride with other acid chlorides.

Thermic Researches on Glyoxylic Acid.—M. de Forcrand.—Not susceptible of useful abstraction.

The Oxidation of Sebacic Acid.—H. Carette.—The oxidation of sebacic acid yields almost exclusively succinic and adipic acids and normal propylene dicarbonic acid.

A New Means of Verifying the Purity of Volatile Bodies.—E. Duclaux.—The author utilises the proces

of fractional distillation proposed in his thesis. On distilling a known volume of the solution of an alcohol or a volatile fatty acid, of which equal portions are collected, the quantities of alcohol or of acid contained in each of these portions goes on increasing or decreasing according to a regular law, characteristic of the body examined, and such that this body is so much the more easily volatile in a dilute solution as it is less pure.

Biedermann's Central Blatt fur Agrikultur Chemie.
Vol. xiv., Part 8.

The Part of Winds in Agriculture, with Especial Reference to the Fertility of the Limagne in Auvergne—Noticed under *Comptes Rendus*, vol. c.

Nature of a Sediment found in an Impure Well.—From the *Comptes Rendus*, vol. xcviii.

Moisture of the Soil in Pure Plantations of Scotch Fir and in those with an Undergrowth of Beeches, &c.—Dr. E. Ramann.—In the latter the proportion of water in the upper strata of the soil is greater than in the former.

Purification of Sewage by Filtration through Peat.—Alex. Müller.—The filtrate, without dilution, is carried beyond the stage of offensive putrefaction.

The Continuous Cultivation of Wheat on the Experimental Field at Rothamsted.—B. Lawes and H. Gilbert.—From the *Journal of the Royal Agricultural Society of England.*

Production of Fat in Cattle.—Prof. W. Henneburg.—The poverty of a food in fatty matter does not interfere with its efficiency in the production of fats.

Influence of Bile, its Acids and Salts upon Saccharification and the Formation of Peptone.—H. Chittenden and W. Cummins.—Already noticed.

Conveyance of Nutrient Matter from the Intestine into the Lymphatic Vessels.—E. A. Schæfer.—From the *Proceedings of the Royal Society.*

Contribution to the Knowledge of Milk.—Prof. W. Fleischmann.—An examination of the accuracy of the constants in the author's formulæ for calculating the total solids of milk from its sp. gr. and from the percentage of fat.

Comparative Experiments with Earth-nut Cake and Rye-meal on Milking Cows.—F. Meyer.—Ground earth-nut cake gave a better result than rye-meal.

The Value of Different Feeding Beets.—Prof. A. Meyer.—The kind known as "Golden Tankard" yields per acre nearly double the amount of nutritive matter as compared with Mammoth and Oberndorfer.

Experiments on Feeding Sheep with Sugar.—Prof. W. Henneberg.—It appears that the consumption of 100 lbs. sugar increased the living weight of the animals by the value of $31\frac{5}{100}$s.

Relations between Harvest-Time and Climatic Relations.—Prof. H. Karsten.—In the season of active vegetation there are two maximum periods of rain-fall, viz., the last week of June and the first week of July, and again from the middle of August to the middle of September. If, therefore, hay can be secured before June 24th the prospects of a good crop are favourable. The mean harvest time for barley, peas, wheat, and oats falls in North Germany prior to the beginning of the second rainy period.

Chemical and Physiological Action of Light upon Chlorophyll.—Timiriazeff.—From the *Comptes Rendus.*

On Glykogen in Plants.—Leo Errera.—The author shows that starch and glykogen are isomers or polymers.

Mineral Matters in the Seeds of the chief Forest Trees.—R. Hornberger.—The fruit of the elm gave the largest proportion of mineral matter, then follow the plane, pine, fir, ash, birch, beech, and oak, and lastly the alder and the larch.

Chemical Composition of the Banana.—L. Ricciardi.—The green banana contains one-eighth of its weight of starch. In the ripe fruits this disappears along with the tannin and the organic acids.

Digestibility of Different Kinds of Cheese.—Dr. von Klenze.—The complete digestion of cheese depends principally on its ripeness and only secondarily on its quality.

Journal de Pharmacie et de Chemie.
Series 5, Vol. xii., No. 11, December 1, 1885.

Action of Arsenic, Lead and Zinc on the Vegetable Organism.—MM. Nobbe, Baesler and Will. Already noticed.

Paratoluidine Sulphate as a Reagent for Nitric Acid.—From the *Moniteur Scientifique.*

Researches on Factitious "Fruit Essences."—MM Poincaré and Vallois.—All these substances produce in dogs, guinea-pigs, &c., various grave symptoms, but no danger seems to be apprehended from their ingestion in minute doses.

Apparatus for the Determination of Oxygenated Water.—M. Maurice de Thierry.—This memoir requires the accompanying figure.

No. 12, December 15, 1885.

Assay of Essences. Value of Classical Methods.—P. Carles.—The method with fatty oils is not trustworthy. The water and the calcium chloride methods detect falsification with alcohol even in minute quantities.

Digestion of Fatty Bodies.—E. Bourquelot.—A physiological paper.

Paralysis by Neuritis following upon Subcutaneous Injections of Ether.—M. Arnozan.—This paper offers no chemical interest.

Characteristics of Blood in Urine.—A. Luchini.—From the *American Journal of Pharmacy.*

Determination of Uric Acid.—E. Ludwig.—From 100 to 200 c.c. of urine is treated with magnesia mixture and an ammoniacal solution of silver nitrate. The uric acid is precipitated as a magnesium and silver salt, and the phosphoric acid as a magnesium and ammonium phosphate. The precipitate is collected on a filter, washed with ammonia-water, and heated with a solution of an alkaline monosulphide which converts the uric acid into a very soluble alkaline urate. The whole is filtered, the filtrate is acidified with hydrochloric acid, and reduced to a small bulk by evaporation, when the uric acid is thrown down in crystals. These are collected on a filter, washed with water, dried, washed with carbon disulphide to remove traces of sulphnr, dried, and weighed (*Archiv der Pharmacie*).

The Caseine of Milk and the Action of Rennet.—M. Eugling.—From the *Journal of the Chemical Society* and *Land. Versuchs-station.*

Detection of Potato Spirit.—M. Hager.—The reagent is a solution of 1 part mercury nitrate in 9 parts of water. It is acidulated with a trace of nitric acid and allowed to stand over metallic mercury until it is clear. If to 3 c.c. of absolute alcohol or wine alcohol at 90 per cent 3 drops of the test-liquid are added and the mixture shaken up, it becomes milky, takes a yellowish white tint, and after standing for some hours it leaves a pale yellow deposit at the bottom of the bottle. Corn spirit gives the same result if free from acetic ether or similar ethers. With potato spirit the mixture takes a bluish white tint, and the precipitate formed in nine to twelve hours is only about one.

third of the bulk of that given by pure spirit, and is white, whilst the supernatant liquid has a bluish opalescence.

Journal für Praktische Chemie.
New Series, Vol. xxxii., Parts 6, 7, 8, and 9.

Researches from the Chemical Laboratory of the University of Leipzig.—These consist of memoirs by H. Schœne, on chloro-carbonyl sulphamyl and its action upon nitrogenous compounds; by M. Seidel, on the action of chloro-carbonic acid upon phenyl- and diphenyl-sulphurea; and by Fr. Gumpert, on the knowledge of phenyl-isocyanate.

Electro-Chemical Studies.—W. Ostwald.—In this third treatise the author discusses the influence of the composition and constitution of acids upon their electric conductivity. The memoir is exceedingly voluminous, and is incapable of useful abstraction.

Ultramarine Blue in the Moist Way.—Fr. Knapp.—The blue colour ordinarily produced by roasting the "ultramarine-mother" (the mass obtained by the preliminary ignition of china-clay, soda, and sulphur) can also be produced in the moist way. For this purpose the aluminium silicate must be heated to a certain degree with sodium carbonate and sulphur, and the product of the ignition must then be digested for some time with a solution of sodium sulphide. If kaolin or any analogous silicate is treated at once, without ignition, with a solution of sodium sulphide, no blue colonr is produced, even after digestion for months.

The Behaviour of Selenious Acid with Sulphurous Acid.—Hans Schulze.—The author establishes that, contrary to the general opinion, sulphurous acid reduces selenium dioxide in the absence of hydrochloric. This result takes place only in certain proportions, and most decidedly when 1 c.c. of sulphurous acid solution is mixed with 10 c.c. of the solution of selenious acid. It appears that selenium may exist in a soluble state. It is the first element which has hitherto been obtained in a colloidal, soluble state.

Calorimetric Researches.—These consist of a paper by F. Stohmann and P. Rodatz, on the thermic value of the acids of the fatty series; and a memoir by F. Stohmann, on the thermo-chemical relations of the alcohols and acids of the fatty series.

Apparatus for Laboratories.—J. Walter.—The appliances described and figured are an exsiccator, with arrangement for heating, and a dropping funnel.

Smaller Communications.—E. von Meyer.—P. Richter has obtained anisic acid by preparing a solution of basic potassium para-oxybenzoate, and adding an excess of potassium methyl-ether sulphate, evaporating to dryness, stirring diligently towards the end, and putting the residue into hot dilute hydrochloric acid. The precipitate thus obtained is re-crystallised from water to which a little alcohol has been added.—Pfitzinger, on mixing phenyl-hydrazin with benzol, has obtained a crystalline body, apparently an impurity in the phenyl-hydrazin. It forms small leaflets, greasy to the touch; it contains sulphur, is insoluble in water, scarcely soluble in benzol, and melts at 96°. Pfitzinger is engaged with the examination of this product.

On Certain Methylene Compounds.—L. Henry.—From the *Comptes Rendus*.

Justus Liebig's Annalen der Chemie,
Vol. ccxxx., Part 3.

On Chlorine Monoxide.—K. Garzarolli-Thurnlackh and G. Schacherl.—The author assigns to this compound the formula Cl_2O. Liquid chlorine monoxide is dark brown, its vapour a yellowish brown. It is not, as it is commonly stated, decomposed on brief exposure to the sun's rays. Its solution in water is of a fine golden-yellow colour. The gas has a very unpleasant odour and attacks the respiritory organs severely. The vapour-density of this compound was found in two experiments as 43·69 and as 43·42; calculation gives it as 43·35.

Communications from the Chemical Laboratory of Greifswalder.—These consist of memoirs by Dr. H. Hasse on amido-toluol disulphonic acid; by Dr. G. Foth on nitro-toluidin sulphonic acid; by Dr. L. Richter on two disulphonic acids of paratoluidine; and by Dr. J. Sartig on ortho-amido-metaxylol sulphonic acid.

Volumetric Determination of the Alkaline Earths and of Combined Sulphuric Acid.—O. Knöfler.—Reserved for insertion at some length.

On Lupanine.—Max Hagen.—Lupanine is an alkaloid obtained from the seeds of *Lupinus angustifolius*. It is obtained as a syrup of the consistence of honey, of a pale yellow colour with a green fluorescence. It has a strong alkaline reaction, an intensely bitter taste, and an unpleasant odour like that of hemlock. The alkaloid forms with hydrochloric acid white clouds like ammonia. It expels ammonia from its salts. In an excess of cold water it forms a turbid solution and is almost entirely deposited on the application of heat. It dissolves with difficulty in cold alcohol, but readily in ether and chloroform. Baumert's lupinine (from *Lupinus luteus*) and lupinidine do not occur in *L. angustifolius*. The seeds of this latter species contain no other alkaloid than lupanine, $C_{15}H_{25}H_2O$, a monacid tertiary amine.

Vol. ccxxxi., Part 1.

Communications from the Physico-Chemical Laboratory of the University of Leipzig.—These consist of papers by W. Epstein, on the condensation of cinnamic aldehyd with acetacetic ether and ammonia; and by Franz Engelmann, on the action of acetaldehyd and ammonia upon acetacetic ether or benzoyl-acetic ether.

On the Non-Crystalline Products of the Action of Diastase upon Starch.—H. T. Brown and Dr. G. H. Morris. Among the principal results of this investigation are:—If extract of malt is allowed to act upon starch-paste at any temperature above 40°, the specific rotatory power of the total product and that of reducing copper oxide are such as to be explained only by the exclusive presence of maltose and a non-reductive dextrine of $[\alpha]$ 13.86, 216°. If the products of such a transformation are fractionated with alcohol, the optical and the reductive products of the several fractions are fully in harmony with the assumption that these products consist exclusively of maltose and dextrine.

Bulletin de la Société Chimique de Paris.
Vol. xliv., No. 11, Dec. 5, 1885.

On Three New Compounds of Rhodium.—Camille Vincent.—The author has obtained the rhodio-chlorides of mono-, di-, and trimethyl ammonium. The first of these compounds forms long, slender crystals, of a deep garnet-red colour. They are anhydrous, and unalterable even at 140°. The dimethyl ammonium compound is deposited in large ortho-rhombic prisms, of a dark garnet-red colour. They contain 3 mols. of water, and are efflorescent. The tri-compound forms long garnet-coloured prisms, very soluble, containing 9 mols. of water. They are very unstable.

Bulletin de l'Association des Elèves de M. Fremy.
October, 1885.

This issue also contains no original papers on chemical subjects.

Archives Neerlandaises des Sciences Exactes et Naturelles. Vol. xx., Part 3.

Chemical Equilibrium in Gaseous Systems or in those Existing in Dilute Solution.—J. H. van't Hoff. —An extensive memoir, illustrated with a number of diagrams.

On Oxygenated Water.—A translation from the *Chemiker Zeitung.*

MISCELLANEOUS.

Science in Japan.—S. Tegima, Minister of Education, Tokio, Japan, has obtained leave to have translated into Japanese Prof. Guthrie's Syllabus of Instruction in Elementary Practical Physics as pursued at the Physical Laboratory of the Normal School of Science and Royal School of Mines, South Kensington. The Japanese Government proposes to introduce this system of practical instruction into the elementary schools as well as into the normal schools of Japan. Prof. Guthrie has promised to write a preface to the translation.

NOTES AND QUERIES.

*** Our Notes and Queries column was opened for the purpose of giving and obtaining information likely to be of use to our readers generally. We cannot undertake to let this column be the means of transmitting merely private information, or such trade notices as should legitimately come in the advertising columns.

Phosphorus.—Can any of your readers inform me if, up to the present time, any efforts have been made to extract phosphorus either from fossil bones, phosphate of lime, or from phosphoretted iron ores of the oolitic or lias series, either in England or abroad? And if so, have the attempts proved either scientifically or commercially a success?—Enquirer.

MEETINGS FOR THE WEEK.

Monday, 18th.—London Institution, 5.
—— Medical, 8.30.
—— Society of Arts, 8. (Cantor Lectures). "Friction," by Prof. H. S. Hele Shaw.
Tuesday, 19th.—Institution of Civil Engineers, 8.
—— Royal Institution, 3. "The Astronomical Theory of the Great Ice Age," by Prof. R. S. Ball.
— Pathological, 8.30.
Wednesday, 20th.—Society of Arts, 8. "Results of Experiments on Mechanical Motors for Tramways made by the Commission at the Antwerp Exhibition," by Capt. Douglas Galton.
—— Meteorological, 7. (Anniversary).
Thursday, 21st.—Royal, 4.30.
—— London Institution 7.
—— Royal Society Club, 6.30.
—— Chemical, 8. "Influence of Silicon on the Properties of Cast-iron, Part III.," by Thomas Turner. "Chemical Action of Pure Cultivations of Bacterium aceti," by Adrian J. Brown. SCIENCE IN THE LAW-COURTS.

We regret to find that whilst almost every disinterested person views the present position of experts in the law-courts with dissatisfaction, few are willing to discuss this important public question. Our contemporary, the *Journal of Gas Lighting*, however, forms an exception, and accuses us of having, in our article of Jan. 1, treated his "temperate plea" with abuse and even ridicule. Where the abuse and the ridicule in our reply are to be found is not clearly apparent. We certainly called in question a remarkable assertion that the Courts in the Strand are the "supreme Temple of Arts, Sciences, Literature, and Humane Culture." This contention he has neither justified nor withdrawn, though he has now toned it down, pronouncing the "examinations and cross-examinations of expert witnesses as marking the high water level of the departments of human activity for which they speak"—a very different proposition. But we must here ask whether a Scientific Commission acting as Assessors would not perform the same task much more satisfactorily, because no one would have the opportunity to interrupt, to misinterpret, or to perplex judges and jury?

We have pointed out the errors of our contemporary in pronouncing the Royal Society and other learned societies "educational institutions," and we have shown that in papers read before such societies, or communicated to scientific journals, great men—or for that matter small men—cannot "circulate rubbish." These points, though damaging to his argument, the *Journal of Gas Lighting* now passes over. But he writes, "would any patentee . . . rest content with a *colourless report* (*sic!*) such as would be compiled with reference to his claims by a disinterested Scientific Commission?" Why should he not, unless he has reason to fear the pure white light of truth? Coloured testimony is the very evil against which we are contending, and we have to thank our contemporary for having thus, in the passage just quoted, admitted that the reports of Assessors such as we recommend would be the truth, and, as far as human knowledge extends, the whole truth and nothing but the truth.

The *Journal of Gas Lighting* further writes:—"It really appears that our contemporary is so scandalised at the propensity of men of science, when in the witness-box, to manipulate facts, that it would spare them the temptation. It is scarcely a complimentary view of the character of men of science." Now if the *Journal of Gas Lighting* will kindly refer to the article in *Nature* for Nov. 26, he will find that it is not we who take an uncomplimentry view of the character of men of science. Our object is to render it impossible for gainsayers to speak of experts as it is there done.

Our contemporary feels—or, if we may borrow an expression of his own, feigns to be—astounded that we should consider unwarranted assumptions, slips, and blunders as the outcome of the system of examination and cross-examination. But he surely does not think that such flaws would be found in the reports which we recommend. On the present system the expert, however conscientious and however thoroughly he may be master of the subject, unless he also possesses the "coolness, the verbal dexterity, the ready wit," and other attributes enumerated by *Nature*, may often fall into such mistakes. Fall, do we say? It is the very object of opposing counsel to lead or drive him into them. Nay, we must not forget the admission of *Nature*, that "too much knowledge or conscience" are not the qualities to enable a scientific witness to hold his own in a court of law.

It is perfectly true there exist "one-sided reports, papers written to order, advertising addresses, &c." But are these ever produced by members of a body such as the Assessors whom we are proposing?

Our objects in this discussion are to spare the money of litigants, to economise the time of the Courts, to enable judges and juries to see the truth directly and not through the intentionally perturbing medium of a sharp and one-sided Q.C., and last, though not least, to place scientific experts in a more worthy position and guarantee them against the insults to which they are now exposed in the witness-box. We can only regret that our contemporary does not see his way to co-operate for the attainment of such ends.

A NEW METHOD FOR SEPARATING ARSENIC FROM THE ALKALINE EARTHS.

By L. W. McCAY, M.A., D.Sc.

G. Chancel* was the first chemist to propose the use of argentic nitrate as a suitable means for separating P_2O_5 from the alkaline earths. His method is recommended by Fresenius,† who pronounces it good and convenient.

Some time ago Drs. Kratschmer and Sztancovánszky,‡ in an article upon the estimation of P_2O_5 with silver, brought out the results of their work upon the separation of P_2O_5 from the alkalies and alkaline earths with argentic nitrate. Their test analyses are numerous and very satisfactory. The ease, sharpness, and accuracy of the process lead these chemists to tend it their highest recommendation.

Now since it is possible, by means of silver solution, to effect a complete separation of P_2O_5 from the earths, reasoning analogically, the presumptions are that, in a similar manner and by similar means, As_2O_5 can be satisfactorily separated from this group of oxides.

During the last year I have been engaged in an exhaustive examination of the Reich method for determining arsenic, which, it will be remembered, depends on the fact that argentic arseniate is insoluble in water; and having been once or twice in the position to separate As_2O_5 from the alkaline earths, it seemed feasible to try whether, by observing proper precautions, it would not prove possible to accomplish the separation by the aid of argentic nitrate.

To test the matter I dissolved 5 grms. H_2KAsO_4, 1 grm. $Ba(NO_3)_2$, 1 grm. $Sr(NO_3)_2$, 1 grm. $Ca(NO_3)_2$, and 1 grm. $Mg(NO_3)_2$ in a little dilute nitric acid, and diluted the solution to 500 c.c. Every 10 c.c. contains, theoretically, 0·0416 grm. As = 0·0638 grm. As_2O_5. By actual analysis of the dihydro-potassic arseniate I found a quantity which would represent, per 10 c.c., 0·0413 grm. As = 0·0633 As_2O_5.

I proceeded as follows:—10 or 20 c.c. were pipetted into a little beaker, 50 c.c. water were added, and the liquid was heated to boiling. More than a sufficient quantity of argentic nitrate to combine with the As_2O_5 was then run in, the beaker was removed from the flame, and its contents were rendered very faintly alkaline. This was accomplished by bringing the beaker under a clip burette containing dilute ammonic hydrate, and permitting the alkali to drop in slowly, the contents of the glass being kept in a constant and violent state of agitation. By means of this vigorous stirring the argentic arseniate is made to coagulate and settle completely, leaving the supernatant liquid clear and limpid. As soon as the very

* *Comptes Rendus*, 49, 997.
† "Einleitung zur Quant. Chem. Analyse," 6 Aufl., I.B., S. 523
‡ *Zeits. f. Anal. Chem.*, 21 Jahrgang, 1882, S. 523.

dilute ammonic hydrate no longer produced a cloud in the clear upper stratum of liquid, and the reaction of the same was just* alkaline, the contents of the beaker were again well stirred, and the whole was permitted to stand until cold. This cooling was generally hastened by placing the beaker in a dish of cold water. The liquid was thereupon filtered, the reddish brown precipitate of argentic arseniate washed by decantation, and (1) dissolved in nitric acid and the silver determined *à la* Vollhard; or (2) dissolved in ammonic hydrate, caught, evaporated, and weighed in a little thin platinum dish.

(1.) $324Ag = 75As = 115As_2O_5$.
(2.) $463Ag_3AsO_4 = 75As = 115As_2O_5$.

Volumetrically.

I.

C.c.	Grm. H_2KAsO_4.	C.c. N/20KCNS.†	Grm. As.	Grm. As_2O_5.
10	0·1	16·4	0·0410	0·0628
10	0·1	16·4	0·0410	0·0628
10	0·1	16·5	0·0412	0·0632
10	0·1	16·5	0·0412	0·0632

As present = 0·0413 grm.
As_2O_5 present = 0·0633 grm.

II.

C.c.	Grm. H_2KAsO_4.	C.c. N/20KCNS.	Grm. As.	Grm. As_2O_5.
20	0·2	32·9	0·0823	0·1261
20	0·2	32·9	0·0823	0·1261

As present = 0·0826 grm.
As_2O_5 ,, = 0·1266 ,,

The filtrates were in this case carefully tested for arsenic, but with negative results.

Gravimetrically.

III.

C.c.	Grm. H_2KAsO_4.	Grm. Ag_3AsO_4.	Grm. As.	Grm. As_2O_5.
10	0·1	0·2535	0·0410	0·0628
10	0·1	0·2532	0·0410	0·0628
10	0·1	0·2540	0·0411	0·0631

Here each precipitate, after weighing, was dissolved in nitric acid and titrated. I obtained:—

	C.c.		Grm.		Grm.	
(1.)	16·4	N/20KCNS	= 0·0410	As	= 0·0628	As_2O_5.
(2.)	16·4	,,	= 0·0410	,,	= 0·0628	,,
(3.)	16·5	,,	= 0·0412	,,	= 0·0632	,,

The presence of small quantities of Fe_2O_3 and Al_2O_3 in no way affects the accuracy of the results. As a proof of this statement I offer the two following estimations—to (1) three and to (2) six drops of a moderately strong nitric acid solution of Fe and Al were added. The hydrates of these metals are indeed precipitated along with the argentic arseniate. But they do not interfere with the subsequent determination of the arsenic, inasmuch as they simply dissolve in the nitric acid or are left intact by the ammonic hydrate. The tests were made volumetrically.

(1.) 20 c.c. required 32·85 c.c. N/20KCNS = 0·0821 grm. As = 0·1260 As_2O_5.
(2.) 20 c.c. required 32·90 c.c. N/20KCNS = 0·0823 grm. As = 0·1261 As_2O_5.

The method works well, and I have no hesitation in recommending it.

In the analysis of such minerals as pharmacolite, berzeliite, and haidingerite it will be found extremely convenient.

Princeton, N.J., U.S.A.
Dec. 15, 1885.

* If too much alkali be added the excess can be removed by means of a drop or two of dilute acetic acid.

† Modern System. *See* Clemens Winkler's little work, "Die Massanalyse nach neuem titremetrischem System."

ON THE VOLUMETRIC METHOD OF DETERMINING ALUMINA.*

By Dr. K. T. BAYER.

In the Chemical News, vol. lii, p. 311, is an article by R. W. Atkinson on my method of titrating alumina. In the first place, I must express my gratitude for the trouble he has taken in submitting my process to investigation. Nevertheless, I cannot help submitting here a brief reply to, and perhaps correction of, his statements.

I regret not having been sooner acquainted with the researches of R. T. Thomson, which would have saved me much trouble and work in searching for a suitable principle for my purpose. But I must remark that the article which appeared in the December issue of the *Zeitschrift fur Analytische Chemie* had been sent a full year previously to the editors of that journal, though subsequent additions and, in part at least, causes of a personal character delayed its appearance.

In the meantime I despatched to the editors of the *Zeitschrift fur Analytische Chemie* the MS. of a second memoir on this subject, giving more exact details on the execution of the process. At first I obtained as uncertain results in the titration—especially on employing litmus—as those mentioned by Mr. Atkinson, until I succeeded in discovering the conditions under which the results become trustworthy. I must therefore refer to this second memoir, mentioning here merely that I also use phenolphthalein, and that I soon abandoned litmus.

As regards the second point mentioned by Mr. Atkinson,—the difficulty in detecting the final reaction when using tropeoline as indicator—I certainly in my memoir recommended the use of the comparative liquid for "inexperienced" operators; but I must here remark that the use of this comparative liquid is indispensable, since, as Mr. Atkinson very justly observes, without this precaution an error of 0·2 to 0·3 c.c. may be readily committed by using too much normal acid.

In titration with tropeoline as indicator, I add quite at the beginning an excess of normal acid, so that the liquid may retain its red colour, even after standing for two to three minutes and being well stirred. I then titrate back with normal soda. If the acid has at the outset dissolved all the alumina the precise neutralisation appears to be more easily effected with soda than by the inverse procedure.

By operating in this manner, with some practice exactly the same values will be obtained in two or more successive titrations of the same liquid. Any differences which may occur range at the outside up to 0·1 c.c., no matter how many c.c. of sulphuric acid have been taken. In order to eliminate this error as far as possible, it is well to use so much of the liquid to be titrated that the sulphuric acid to be used for the alumina may amount to at least 12 to 15 c.c., or, in other words, that it contains 0·2 to 0·3 grm. Al_2O_3.

St. Petersburg, Dec. 27, 1885 (Jan. 8, 1886).

* Communicated by the Author.

A Characteristic Reaction of the Sulpho-conjugated Derivative of Magenta.—Dr. C. Blarez.—One of the most sensitive reagents for detecting this compound is lead dinoxide or plumbic acid. All the red derivatives of coal-tar and the red vegetable colours in a dilute aqueous solution are completely decolourised if shaken up for some time with lead dioxide. If the aqueous solution, in place of being neutral, is slightly acidulated, especially with tartaric acid, all these reds are likewise decolourised except sulpho-conjugated magenta. This process is particularly applicable to the detection of this colour in sophisticated red wines.—*Journ. de Pharm.*, 1, 1886.

A NEW METHOD OF PRECIPITATING AND ESTIMATING MANGANESE, ALSO IRON INDIRECTLY, BY MEANS OF HYDROGEN PEROXIDE.

By JOHN JAMES BARLOW.

VALENTIN, in the 4th Edition of his "Qualitative Analysis," page 30, says that—"On exposing an ammoniacal solution of the soluble double chloride of manganese—($2NH_4Cl,MnCl_2$),—to the action of the air, the whole of the manganese is gradually precipitated as dark brown dimanganic-dioxydihydrate,—

$$\left\{\begin{matrix}MnOHO\\MnOHO\end{matrix}\right.$$

and that this reaction is characteristic for manganese compounds."

Now, I find that if I blow air into this solution, the same thing happens much quicker, the length of time required for blowing to complete precipitation depending on the amount of manganese present. The equation expressing the change which occurs may be written thus :—

$$2(2NH_4Cl,MnCl_2)+4NH_3+3H_2O+O=$$
$$=Mn_2H_2O_4+8NH_4Cl.$$

According to this equation, it is evident that before any change can take place the water must be decomposed, the hydrogen combining with the chlorine in the manganous chloride, MnCl, to form HCl; which HCl immediately combines with the excess of ammonia present, and part of the hydrogen combining with the manganese along with the oxygen of the water and the free oxygen to form the compound $Mn_2H_2O_4$.

These facts explain why it takes such a long time to precipitate the manganese, which has occupied me more than one hour to precipitate about 0·2 grm. of manganese completely.

I find, however, that if, instead of air, I use a solution of hydrogen peroxide, I obtain a complete precipitation of the manganese almost immediately; the precipitate settles rapidly, is easily filtered, and completely insoluble in NH_4Cl,NH_4HO, and ammonium salts generally; is close-grained, and if dried on a filter can be easily detached from the same; nor does the precipitate bring down any of the oxides of Zn, Ni, or Co.

From the foregoing facts I have worked out and arranged a method of separating the metals in the manganese group, *i.e.*, the metals Fe, Cr, Al, Zn, Mn, Ni, and Co., in a different manner from what has hitherto been adopted, and from my own experience it is very much simpler, quicker, easier to manipulate, does not require so many reagents, and also gives more accurate results than is obtained by any of the other well-known methods. From the table found below it will be seen that the manganese is precipitated immediately after the iron group is precipitated, which is a very great advantage whenever zinc is present, as I have found from a great many experiments. What occurs during the reaction may be represented by the following equations :—

$$(1.)\quad 2(2NH_4Cl,MnCl_2)+3H_2O_2=$$
$$=Mn_2H_2O_4+4NH_4Cl+4HCl+O_2.$$

The hydrochloric acid combines, immediately it is formed, with the excess of ammonia which is present, and so forms ammonium chloride, NH_4Cl, thus,—

$$(2.)\quad 4HCl+4NH_4HO=4NH_4Cl+4H_2O,$$

an additional advantage whenever magnesium compounds are present.

At the time the precipitation occurs, there is a rapid effervesence, due to the evolution of oxygen gas, and I find that, after adding the hydrogen peroxide, it is best to always boil before filtering, and so drive out the oxygen.

I also find that it is not at all necessary to have the manganese in the form of a soluble double chloride, nor to use a quantity of NH_4Cl along with the ammonia. I can obtain quite as accurate results from a solution of manganous chloride, $MnCl_2$, if I use a large excess of NH_4HO, minus the ammonium chloride, excepting, of course, when magnesia is present.

There is always the same difficulty, during a quantitative separation of and estimation of iron and manganese as formerly; simply on account of the utter impossibility to entirely separate the last traces of manganous hydrate from the ferric hydrate precipitate; when the iron is precipitated by ammonia or ammonium carbonate, even on precipitating and re-dissolving the red precipitate three times in succes-

TABLE FOR SEPARATING THE METALS OF THE MANGANESE GROUP.

To the solution containing the Zn, Mn, Ni, Co, Fe, Cr, and Al as chlorides, as well as the chlorides of Ba, Ca, Sr, Mg, Na, and K, add a few drops of HNO_3; boil, then add a strong solution of NH_4Cl and NH_4HO in excess; boil and filter. Re-dissolve the precipitate with HCl, add NH_4HO in slight excess; boil, filter, and mix the two filtrates.

Precipitate—Consists of $Fe_2(HO)_6$, $Cr_2(HO)_6$, and $Al_2(HO)_6$, and also a small trace of $Mn(HO)_2$.* Separate the Fe, Cr, and Al by the usual methods.

Filtrate—Contains the chlorides of Mn, Ni, Co, Zn; also the chlorides of the alkalies and alkaline earths. Warm gently, add NH_4HO to excess,† then a solution of hydrogen peroxide, drop by drop, as long as a precipitate falls down;‡ boil and filter.

Precipitate—Consists of manganese as $Mn_2H_2O_4$. Confirm by fusing on Pt foil with fusion mixture.

Filtrate—Contains $ZnCl_2$, Ni_2Cl_6, Co_2Cl_6, as well as the chlorides of the alkalies and alkaline earths. Add NH_4HO and $(NH_4)_2S$ in slight excess; filter, wash with H_2S water. (Reserve the filtrate and examine it for Ba, Sr, Ca, Mg, Na, and K). Pour dilute HCl (1 : 3) on the precipitate.

Solution—Contains the zinc as chloride. Add NH_4HO and $(NH_4)_2S$. White precipitate confirms zinc.

Residue—Consists of the sulphides of Ni and Co. Examine and separate these by the usual methods.

* If no precipitate is obtained on adding H_2O_2 a little of the precipitate obtained with NH_4HO should be tested for Mn by fusing on Pt foil, as it is impossible to separate a mere trace of Mn when the NH_4HO precipitate is large.

† If there is not an excess of NH_4HO no precipitate is obtained.

‡ Whilst the H_2O_2 is being added strong effervescence occurs, due to the evolution of oxygen gas. The precipitated Mn settles out very clean and rapidly, and is easily filtered.

sion, I could still get the characteristic green manganate of soda by fusing with a little of the red precipitate with fusion mixture on platinum foil; but if no iron was present with the manganese I had not the slightest difficulty, and I obtained very good results indeed.

To overcome the above-mentioned difficulty of estimating accurately both the iron and the manganese, when present together, I use the following process, which gives splendid results.

To the solution containing the chlorides of iron and manganese (other metals may be present, excepting chromium and aluminium, though the best results are obtained if foreign substances are absent) I add a solution of NH_4Cl, then strong NH_4HO in excess; boil, then add lastly hydrogen peroxide solution as long as a precipitate falls, then boil a minute or two, filter, wash two or three times with hot water, ignite, and weigh the mixed oxides together as mixture of $Fe_2O_3+Mn_3O_4$.

I then put the mixed oxides of iron and manganese into a little flask (holding about 70 c.c.), and distil in hydrochloric acid, passing the evolved chlorine gas into KI solution, and then estimating the amount of iodine liberated by a standard solution of sodium hyposulphite.

The weight of the mixed oxides obtained, minus the weight of the Mn_3O_4, gives the amount of Fe_2O_3.

In precipitating both metals with H_2O_2 there is a great advantage over the old method of precipitating by means of NaHO or Na_2CO_3, as hydrate or carbonate. I always obtained too much iron, on account of not washing out entirely the free NaHO or Na_2CO_3, and always too little manganese, because the manganese precipitate is slightly soluble in excess of sodium hydrate or carbonate.

By using the potassium iodide method, and precipitating both iron and manganese together, by means of hydrogen peroxide, I have found manganese, and also estimated it, in substances which have been thought, and even stated, as free from manganese, when the other methods were adopted.

THE VOLUMETRIC DETERMINATION OF THE ALKALINE EARTHS, AND OF COMBINED SULPHURIC ACID.

By O. KNÖFLER.

The author uses as indicator a mixture of phenolphthalein and methyl-orange, 1 grm. of each dissolved in 250 c.c. of alcohol.

After this indicator has been added, the solution of the substance in question is mixed with hydrochloric acid to incipient acid reaction (reddening of the methyl-orange). If carbonic acid is present it is expelled by boiling. Quinque-normal sodium carbonate is then dropped in; the alkaline reaction which appeared at first disappears immediately in case of barium and strontium salts; more slowly, though within a few seconds, with calcium salts.

As soon as a faint rose-colour remains 1 c.c. more of the sodium carbonate solution is added, and the liquid, which is now a deep red, is filtered through a wet folded filter, and washed once with water. The filtrate is then titrated back with quinque-normal acid until the methyl-orange reaction appears. If a good filter is used the filtration is complete in one to two minutes; once washing is sufficient, as only from 1 to 2 c.c. of quinque-normal carbonate solution is present in excess. The final reaction with methyl-orange can be very distinctly recognised after a little practice. Boiling up is not necessary, as carbonic acid does not act upon methyl-orange.

The volume of the solution of sodium carbonate used after deduction of the c.c. of acid employed corresponds to the quantity of the alkaline earth which was present. For preparing the standard solution 10·583 grms. of anhydrous sodium carbonate, chemically pure, was dissolved in water so as to make up 1000 c.c., and the hydrochloric acid was standardised accordingly.

An excess of 1 c.c. of the sodium carbonate solution was found sufficient to precipitate all the baryta. The same quantity was found sufficient in case of strontium and calcium. Calcium carbonate falls less quickly than barium and strontium carbonates, but still within a few seconds. The precipitation is rather slower in dilute solutions, but it is still quantitative.

If the three alkaline earths are present in solution together, a portion is first titrated as above. The metals are separated, and the single constituents are either determined from the difference (after one metal has been removed from the solution), or the isolated salts are titrated with the quinque-normal sodium carbonate.

Baryta is separated from strontia and lime by means of potassium chromate. The barium chromate is either weighed or it is determined volumetrically by Wildenstein's process. Attempts to separate the barium as chromate, and to titrate the filtrate with the quinque-normal solution of sodium carbonate gave no results, as the sodium acetate (which must be added to prevent the simultaneous precipitation of strontium chromate) makes the final reaction indistinct.

Strontia is best separated from lime by treating the dry nitrates with a mixture of ether and alcohol. The solution containing the lime is easily titrated, as above, after the expulsion of the ether.

All attempts to precipitate salts of magnesia with sodium carbonate led to no result, as magnesium carbonate falls not merely slowly, but imperfectly. Such salts must not be present in determinations by the above method. The separation with ammonium chloride is inadmissible. Magnesium salts may, however, be removed along with iron, &c., by adding to the hot solution soda-lye free from carbonate, until the reaction is distinctly alkaline.

In this process the previous addition of ammonia or its salts must be entirely avoided.

In the determination of combined sulphuric acid there is required, besides the above-mentioned solutions of sodium carbonate and hydrochloric acid, a quinque-normal solution of barium chloride. The process is as follows:—The solution in question is coloured with phenol-phthalein and methyl-orange, and mixed with quinque-normal hydrochloric acid to incipient acid reaction. It is then boiled up and mixed with a few tenths of a c.c. of the standard sodium carbonate solution. This must produce a distinctly alkaline reaction (otherwise carbonic acid is present, and must be expelled by boiling). The quinque-normal barium chloride is then dropped in, with agitation. As long as sulphuric acid is in solution it seizes upon the barium. As soon as it is all precipitated any further barium chloride undergoes double decomposition with the sodium carbonate, and the alkaline reaction disappears. As the point of disappearance is not sufficiently well marked a further c.c. of the barium chloride is added; the whole is boiled up, and, without filtering, quinque-normal sodium carbonate is dropped in until the alkaline reaction appears. The mixture is then poured upon a folded filter, washed once with water, and the filtrate is titrated back with quinque-normal hydrochloric acid. The c.c. of $BaCl_2$ consumed + acid − total c.c. of quinque-normal sodium carbonate consumed, multiplied by 0·008, give grammes of SO_3.

This method is not universally applicable. Those substances must be absent which interfere with the volumetric determination of the alkaline earths. If lime is present two titrations are needed: the lime is first determined in one portion, as above, and then the sulphuric acid, either in the filtrate or in another portion of the original solution, deducting the quantity of sodium carbonate corresponding to the lime. Acids which are precipitated by barium chloride in neutral solutions must not be present.—*Liebig's Annalen.*

THE QUANTITATIVE DETERMINATION OF NIOBIUM.

By T. B. OSBORNE.

NIOBIUM occurs in Nature almost always in connection with tantalum and titanium, in the presence of which it has been heretofore impossible to obtain more than an approximate determination, on account of the close analogy of the behaviour of these three elements, when occurring together, toward reagents.

Marignac proposed in 1866 (*Arch. de Sc.*, xxv., p. 17) the process now generally employed for the determination of niobium, but, as he says in describing his method, only approximate results can be obtained by its use. His method depends on the difference in solubility of the potassium fluorine salts of tantalum, niobium, and titanium. Tantalum forms a salt of the composition TaF_52KF, dissolving at ordinary temperatures in 150 to 200 parts of water acidulated with hydrofluoric acid, and crystallising in fine needles. Niobium, on the other hand, forms a salt of the composition $NbOF_32KFH_2O$, dissolving in 12 parts of water, and crystallising in scales isomorphous with the corresponding titanium salt. The potassium titanium fluoride dissolves in 96 parts of water.

Marignac adds bifluoride of potassium to the solution of the fluorides of tantalum, niobium, and titanium, and concentrates till scales of TiF_52KF or $NbOF_32KF$ appear. The TaF_52KF is filtered and washed with the aid of a pump until the washings no longer give any orange-red precipitate with solution of galls after standing two hours. On account of the solubility of the TaF_52KF the mother-liquor containing the $NbOF_32KF$ must always be a saturated solution of TaF_52KF, and likewise a loss must occur on washing, so that even if the process of crystallisation be several times repeated, as is usually necessary, a very considerable loss must occur. Moreover, the tantalum potassium fluoride cannot be entirely freed from niobium in this way, for I found in preparing TaF_52KF that the niobium cannot be entirely removed by simply crystallising and washing, as I was compelled to re-crystallise several times before the TaF_52KF gave no evidence of the presence of niobium, when tested by reducing with zinc and hydrochloric acid. Titanium will, when present in any considerable quantity, render the application of this method still more uncertain on account of the intermediate solubility of the potassium titanium fluoride and its close resemblance to the $NbOF_32KF$.

From this description it will readily be seen that this method is open to serious objection, and can only find acceptance in want of a better. I therefore undertook an investigation of the reduction with zinc in acid solutions containing niobium, with the hope of discovering a more accurate and less difficult method of determination. The salts of tantalum and niobium I prepared from columbite from Branchville, Connecticut, in the following way:—The mineral was ground to pass a sieve of 100 meshes to the inch, and 500 grms. fused with bisulphate of potassium in a platinum dish, 100 grms. at a time. When thoroughly fused the mass was immediately poured into cold water, which caused the separated tantalic and niobic acids to granulate and expose a large surface to the action of the water, whereby the solution of the bisulphate of potassium was very materially promoted, and the lumps broke up easily on stirring, the tantalic and niobic acids separating partly in a flocculent and partly in a granular form.

After washing by decantation the residue was treated with ammonium sulphide, and then filtered and washed to remove any tin or tungsten which might be present. Hydrochloric acid was then added, and, after washing, the residue was obtained free from iron and manganese. The residue was next treated with hydrofluoric and sulphuric acids, in order to remove any silica, precipitated with ammonia, and washed free from sulphates. The tantalic and niobic acids thus obtained were dissolved in an excess of hot hydrofluoric acid and carbonate of potassium added gradually, and, after cooling, the TaF_52KF filtered off. The crude TaF_52KF was re-crystallised several times, and washed till no reduction whatever took place on testing with zinc and hydrochloric acid. The mother-liquor from the crude TaF_52KF was then nearly neutralised with carbonate of potassium, which caused the solution to nearly solidify from the formation of $NbOF_52KF$. This product was then re-crystallised several times, and tested for tantalum by boiling with pure water, when, according to Marignac, if the slightest trace of tantalum were present, it would separate as an oxyfluoride. None was found. Analyses of the $NbOF_32KFH_2O$ thus obtained gave the following results:—

			Calculated.
H_2O	5·92	5·90	5·97
NbO	36·92	36·84	36 87
K_2	26·07	26·13	25·97
F_5	31·09	31·13	31·19
Ti	trace	trace	—
	100·00	100·00	100·00

This analysis shows that the salt was practically pure. The trace of titanium was found by testing with H_2O_2, and amounted to only 0·0066 per cent.

Tantalum when treated with zinc and hydrochloric acid does not reduce. Niobium, on the other hand, forms apparently several reduction products, or at least exhibits colours varying according to treatment. When zinc is added to a dilute hydrochloric acid solution of niobium, a blue colour is formed in the cold; if the acid is strong a brown colour is obtained, which, if the acid is allowed to act on the zinc until nearly neutralised, changes to blue, and an indigo-blue precipitate separates out. When heated to 100° only quite dilute acid solutions give a blue colour, which speedily turn brown. Those containing more acid give a brown colour at once. If sulphuric acid is used instead of hydrochloric, the blue colour appears at first, but on heating with much acid this passes into a brown differing slightly in colour from that produced in the hydrochloric acid solution. A grass-green colour is often obtained in the cold, with both sulphuric and hydrochloric acids, which appears to be intermediate between the blue and the brown as the blue passes into green and this into brown. All solutions strongly acidified with sulphuric or hydrochloric acid give on heating a dark brown colour, which evidently indicates the lowest reduction attainable, while the blue colour marks a higher oxide than the brown or else an incomplete reduction.

The solution reduced with sulphuric acid and zinc is much less stable than that with hydrochloric acid, for on pouring it while warm into water, if the amount of reduced niobium is sufficient, an evolution of hydrogen takes place from the decomposition of the water. With hydrofluoric acid and zinc a violet colour is produced similar to that given by titanium with zinc and sulphuric acid. Under similar conditions titanium gives a green colour.

The first attempts at a quantitative determination of niobium were made with sulphuric acid solutions of $NbOF_32KF$, as sulphuric acid is better suited for titration with potassium permanganate than hydrochloric. It was found, however, that the amount of reduced niobium was very far from constant. More constant results were obtained by pouring the reduced solution into ferric sulphate, but these varied too widely to give any promise of a satisfactory method. Hydrochloric acid was then tried, and iodine solution added till a drop gave a blue colour with a drop of starch solution; then sodium thiosulphate solution in slight excess, then a few drops of starch solution and iodine added till a blue colour appeared. It was found, however, that a dark brownish colour was formed near the end of the titration which so obscured the blue of the starch that very unsatisfactory results were obtained.

I then tried potassium dichromate for titrating, pouring the reduced solution into ferric chloride, but without success.

Potassium permanganate was then returned to, and manganese sulphate or magnesium sulphate added to prevent the action of the hydrochloric acid on the permanganate. It was afterward found that by sufficient dilution the end point could be obtained with all the accuracy desirable without the addition of either magnesium or manganese sulphates. The results are shown in the following table. The reduction was assumed to be to Nb_2O_3.

(Contained about 0·5 gr. TaF_32KF.)

In the above analyses the fluorides were dissolved in water, and the acid added. In the following concentrated acid was added directly to the fluorides .. .. 1·1023 ,, 39·03

0·8395 ,, 38·86

The amount Nb_2O_5 corresponding to the niobium in the $NbOF_32KFH_2O$ is .. .. 44·48

The foregoing series of determinations show that the reduction of the niobium is quite constant for a given strength of acid depending not on its amount, but on its strength. The determinations were made by dissolving $NbOF_32KF$ in water, and adding the indicated amount of acid. The first eight determinations, where 50 c.c. of dilute acid were used, give an average of 34·78. With 40 c.c. the same amount of water was used to dissolve the fluoride; the strength was consequently less, and the average lower, being 34·20. With 30 c.c. 33·56 was found. When concentrated acid was used the amount of water required to dissolve the fluorides was small in comparison with the amount of the acid in solution, so that the amount of water used exerted but little influence on the reduction, but the increased strength of acid raised the average to 37·80. The results obtained when concentrated acid was used to dissolve the fluoride are higher still, the average being 38·94.

Thus we have—

For 30 c.c. HCl, sp. gr. 1·1 .. .. 33·56 p.c. Nb_2O_5.
,, 40 c.c. ,, ,, ... 34·20 ,, ,,
,, 50 c.c. ,, ,, ... 34·78 ,, ,,
,, Concentrated HCl .. .. .. 37·80 ,, ,,
,, Fluorides dissolved in conc. HCl 38·94 ,, ,,

It appears therefore that the amount of reduction increases with the concentration of the acid. The formula for an oxide corresponding to the reduction in the last case would be Nb_8O_{13}. Marignac sought to obtain a formula for this oxide in the same way, and obtained Nb_3O_5. This is very nearly equal to Nb_8O_{13}, since for 8 atoms of niobium there would be 13⅛ atoms of oxygen according to his formula. It is probable that neither of these oxides represents the oxide formed, but that a partial reduction has taken place, as will appear from the results obtained from niobic acid in the following manner:—Ten grms. of $NbOF_32KF$ and 5 grms. of TaF_32KF were accurately weighed, and heated with sulphuric acid in a platinum dish till all the hydrofluoric acid was removed. The acid solution was poured into water, and precipitated with ammonia, washed by decantation, and then thoroughly dried at 100° C. Weighed portions were then ignited, and the total amount of mixed oxides of tantalum and niobium determined. The percentage of niobic oxide in these mixed oxides was calculated from the relative amount of the fluorides of each metal taken. In this way it was found that the mixture of tantalic and niobic acid precipitated and dried at 100° contained 47·36 per cent of Nb_2O_5. Weighed portions were then dissolved in as small an amount of hydrofluoric acid as possible, and 50 c.c. of concentrated acid added, and the reduction carried on at a temperature of about 80° C. for three-quarters of an hour. The amounts obtained were as follows:—

Amount of mixed oxides taken.		Amount of Nb_2O_5 found.
0·6400		46·99
0·6652	Nb_2O_5 present.	47·45
0·7455		46·70
0 7603	47·36 per cent.	46·64
0·8323		46·97

In the above determinations the reduction was evidently to Nb_2O_3. Marignac states that alkali fluorides impede the reduction, and this would explain why the reduction in the foregoing determinations was complete, while in those where the potassium fluoride of niobium was used it was incomplete: as the amount of alkali fluoride was always in the same proportion to the amount of tantalum and niobium constant results might be expected, but it is remarkable that so small an amount of alkali fluoride should exert so great an influence on the reduction, and that the hydrofluoric acid added to dissolve the niobic acid did not also interfere with the reduction. Two analyses were made in order to throw light on this point by adding weighed amounts of potassium fluoride to a mixture of tantalic and niobic acids free from fluorides and containing 45·99 per cent of Nb_2O_5.

Weight of mixed acids.	Weight of KF.	Nb_2O_5 found.	Nb_2O_5 present.
5696	0·0900	43·83	45 99
5405	0·3728	43·87	—

From this it would appear that the *amount* of alkali fluoride exerted no influence, but that its *presence* did. In this case, however, the reduction is proportionally greater than when $NbOF_32KF$ was used.

The influence of titanium was next studied. Titanic acid was treated exactly as the niobic acid, and the following results were obtained:—

TiO_2 found by reduction and titration.		Present.
20·38	20·36	20·48

In order to determine whether both niobium and titanium would reduce together as well as separately the oxides were mixed together, and the niobium determined by deducting from the amount of permanganate used the amount necessary to oxidise all the reduced titanium, and calculating the niobium corresponding to the balance. In this way I obtained the amounts given below:—

Mixture of three acids.	Titanic acid present.	Nb_2O_5 present.	Nb_2O_5 found.
1·1798 grms.	0·0859 grm.	0·4928 grm.	0·4907
0·8145 grm.	0·0687 ,,	0·3357 ,,	0·3314

For the determination of titanium in the presence of niobium the method proposed by A. Weller (*Berichte*, xv., 1882, 2, p. 2592) appeared most suitable. It depends upon a comparison of the colour produced by hydrogen dioxide in an acid solution of titanic acid, with the colour of a solution containing a known amount of titanium. A. Weller, in describing his method, calls attention to its applicability to the determination of titanium in the presence of tantalum and niobium, but says he has not tried it in this case. I therefore undertook to determine the best manner of applying it. I found that it was necessary to use hydrofluoric or hydrochloric acid in order to keep the tantalum and niobium in solution when sufficiently diluted. I found that the first of these acids, even in small amounts, entirely prevented the formation of the colour of titanium with hydrogen dioxide, and that hydrochloric acid deepened it very greatly in proportion to the amount added. It is necessary, therefore, to have the solution free from fluorides, and to have the same amount of acid in the standard solution as in the solution to be analysed. It is very difficult to obtain these conditions, and I was entirely unsuccessful in my attempts to determine the amount of titanium in a solution containing much free acid. I succeeded in obtaining quite satisfactory results, however, by precipitating the strongly acid solution with a small excess of ammonia, and then redissolving the precipitate with as little sulphuric acid as possible, the freshly precipitated niobic and tantalic acids being readily soluble in dilute acid.

In order to test the accuracy of this method a mixture of tantalic, niobic, and titanic acids, containing a known amount of each acid, was dissolved in hydrofluoric acid in a platinum dish, and the excess of acid evaporated off on the water-bath. The fluorides thus obtained were dissolved in concentrated hydrochloric acid, and poured into a glass flask of about 100 c.c. capacity, the platinum dish being rinsed out with concentrated hydrochloric acid. The solution and rinsings amounted to 50 c.c. Amalgamated zinc was then added, and a piece of platinum and the solution allowed to reduce in a stream of carbonic acid for three-quarters of an hour at a temperature of about 80° C. During this process the greater part of the hydrofluoric acid was removed from the solution, going off as silicon fluoride. After cooling thoroughly the reduced solution was poured into a beaker, and diluted to 350 c.c. with distilled water freshly boiled and perfectly cold. A standard solution of potassium permanganate was added till the solution, at first nearly black, became perfectly clear, and a distinct pink colour was produced by the addition of a single drop. To the solution containing the tantalum, niobium, and titanium, ammonia was added in slight excess, and then sulphuric acid till the precipitate produced by the ammonia dissolved entirely. In this way a solution was obtained containing a very small amount of free acid, and practically free from fluorides. This solution was then diluted to 500 c.c., and 50 c.c. brought into a Nesslerising tube and 2 c.c. of hydrogen dioxide added. About 40 c.c. of water was added to another tube of the same dimensions, and then 2 c.c. of hydrogen dioxide. A solution of titanic acid, prepared by evaporating potassium titanium fluoride with excess of sulphuric acid and diluting with water until 1 c.c. equalled 1 m.grm. of titanium oxide, was then run in until the colour in the two tubes was nearly alike. They were then brought to the same volume, and the standard solution of titanium added drop by drop till there was no longer any difference in colour discernible. The number of cubic centimetres of the standard solution multiplied by 10 gave the number of m.grms. of TiO_2 in the solution analysed. By calculating the amount of permanganate solution necessary to oxidise the Ti_2O_3 formed by reduction of this amount of TiO_2, the amount of permanganate employed to oxidise the niobium was found, and from this the amount of niobium calculated. The tantalum was found by subtracting the sum of the niobic and titanic oxides from the sum of the three oxides. In this way the following amounts of each were found :—

	Nb_2O_5.	Ta_2O_5.	TiO_2.
Taken ..	0·3357 grm.	0·2246 grm.	0·0687 grm.
Found ..	0·3314 ,,	0·2289 ,,	0·0667 ,,

It is necessary that during the reduction the heat should not be too great, as the tantalic acid is liable to precipitate and to carry with it both niobium and titanium, and the reduction consequently will be incomplete. If tantalum is not present the solution can be boiled without danger. In order to analyse a mineral containing these three elements the mixed oxides can be obtained in the usual manner by fusing the finely ground mineral with bisulphate of potassium, digesting with water, filtering, heating the residue with ammonium sulphide, washing to remove tin and tungsten if present, treating the residue with dilute sulphuric acid to remove iron, washing, and igniting with ammonium carbonate. After obtaining the joint weights of the oxides, fuse with potassium bisulphate, digest with water, and the residue—washed free from sulphates—dissolve in hot hydrofluoric acid, evaporate nearly dry on the water-bath, and proceed with the reduction and determination as just described. An analysis of Branchville columbite by this method gave the following results :—

Ta_2O_5 ..	18·95	19·44	Specific gravity,
Nb_2O_5 ..	60·95	60·46	5·73
FeO	12·86	12·95	
MnO	7·07	7·00	Oxygen ratio,
	99·83	99·85	1 : 1·03

Marignac constructed a table of specific gravities of columbite which showed that in general the specific gravity increases with the amount of tantalum. The relations which he found hold good for this analysis.—*American Journal of Science*, Vol. xxx., No. 179.

CONTRIBUTIONS TO THE KNOWLEDGE OF SAMARIUM.*

By P. T. CLEVE.

(Continued from page 31.)

Oxide of Samarium, Sm_2O_3.

It forms an almost white powder, having a very slight yellowish tint. It is easily soluble in acids, and is not reduced by ignition in a current of hydrogen. If forms no higher oxide on ignition in oxygen. The oxide is very hygroscopic.

Specific gravity—

1·9113 grms., t° 15°, sp. gr. 8·383
2·1432 ,, ,, 13°, ,, 8·311

Mean of the two determinations, 8·347.
Molecular volume, 41·7.

Hydroxide of Samarium.

It is a gelatinous, white, and bulky precipitate, which absorbs carbonic acid from the air, but to a less degree than the hydroxides of the other cerium metals. It dries to yellowish semi-transparent fragments. It is not soluble in alkalies, but is easily soluble in acids, and expels ammonia from ammoniacal salts if boiled with their solutions.

Salts of Samarium.

The salts of samarium are of a yellow colour, though sometimes almost white; their concentrated solutions are

* Presented to the Royal Society of Sciences of Upsala, Feb. 13 1885.

also yellow, and give a peculiar absorption-spectrum. The taste of the soluble salts is sweetish and very astringent.

Sulphuretted hydrogen gives no precipitate with the salts of samarium.

Sulph-hydrate of ammonia precipitates hydroxide of samarium.

Alkalies precipitate completely hydroxide of samarium, insoluble in excess of alkalies.

Alkaline carbonates give gelatinous and voluminous precipitates, soluble, if recently precipitated, in excess of the reagents. After some time very slightly soluble double carbonates separate out.

Sulphate of potash gives with not too dilute solutions of salts of samarium a white precipitate, very slightly soluble in a saturated solution of sulphate of potash; 100 parts of the saturated solution contain about 0·05 part Sm_2O_3. The solubility is very much influenced by the presence of the other earths. The solubility is increased by the presence of the yttria earths.

Oxalic acid gives in neutral or slightly acid solutions a voluminous, white, and gaseous precipitate, which soon becomes pulverulent and crystalline. It is soluble in boiling nitric acid.

Alkaline oxalates give white, non-crystalline precipitates of double oxalates of samaria with oxalates of alkalies. These precipitates are finely divided and not easy to wash.

Acetate of sodium gives on boiling with dilute solutions of samaria no precipitate.

Hyposulphite of sodium produces on boiling with salts of samarium no precipitate.

Ferrocyanide of potash gives with salts of samarium a yellowish non-crystalline precipitate of ferrocyanide of samarium and potassium.

Tartaric acid gives with salts of samarium a white, voluminous precipitate, soluble in ammonia. The ammoniacal solutions of the tartrate deposit after some time at the ordinary temperature, and immediately on heating, a white powder.

Formiate of ammonia gives with concentrated solutions of salts of samarium, especially on evaporating, a white powder of little soluble formiate of samarium.

Borax and microcosmic salt give with samaria colourless beads.

Peroxide of Samarium.

If basic nitrate of samarium be heated to incipient redness in a current of dry oxygen as long as red vapours are given off, an oxide remains which has a stronger yellow tint than the oxide of samarium. The loss on heating to a white heat was found in two experiments to amount to 1·35 and 2·81 per cent. When dissolved in a solution of a known weight of ammonio-ferrous sulphate mixed with sulphuric acid it did not oxidise more of the ferrous salt than corresponds to 0·1 per cent of oxygen. It seems, then, highly improbable that a peroxide of samarium could be obtained in the manner described.

If peroxide of hydrogen (2 per cent) be added to a solution of a samarium salt no visible change occurs, but on adding ammonia a gelatinous precipitate, perfectly resembling the hydroxide of samarium, is produced. After a short while oxygen is given off in numerous small bubbles. After washing, one portion of this precipitate, suspended in the liquid, was mixed with a known quantity of ammonio-ferrous sulphate. Ferric hydroxide was immediately thrown down. After adding dilute sulphuric acid, the unoxidised excess of the ferrous salt was estimated by permanganate of potash. Afterwards the samarium was determined in the liquid by precipitation with oxalic acid, ignition of the oxalate, and re-precipitation as oxalate.

The experiment gave—

0·7818 grm. Sm_2O_3 and 0·0513 grm. O, or for 100 Sm_2O_3 6·56 O.

This corresponds pretty nearly to—

$$Sm_4O_9,$$

which requires for 100 Sm_2O_3 6·90 oxygen.

If the precipitate be dried over sulphuric acid it forms semi-transparent yellowish pieces, which were powdered several times. Afterwards it was analysed.

0·772 grm. was heated with bichromate of potash in a current of dry air, and gave 0·0178 grm. CO_2 and 0·1180 grm. H_2O.

0·7241 grm. gave by ignition 0·5581 grm. Sm_2O_3.

0·7542 grm. was mixed with 3·1386 grms.—

$$(NH_4)_2Fe2SO_4+6H_2O,$$

and water, sulphuric acid was added (when a great number of small gas-bubbles escaped), and afterwards 23·3 c.c. permanganate of potash (100 c.c. = 0·939 Fe) were required to oxidise the excess of ferrous salt.

In per cent—

		Ratio.
Sm_2O_3	77·07	1
O	4·35	1·23
CO_2	2·31	0·24
H_2O	15·28	3·83
	99·01	

The dry substance analysed, which had been obtained from the nitrate of samarium, contained also a trace of nitric acid.

On comparing the ratio between Sm_2O_3 and O in the moist and in the dry product, it will be seen that comparatively little oxygen was lost in drying.

I have examined the composition of the products formed by the action of peroxide of hydrogen upon the hydroxide of the other earths,* and have found that didymium, lanthanum, yttrium, and erbium all give products of perfectly analogous composition, or agreeing with the general formula R_4O_9, when recently washed and in a moist state. Considering that oxygen was given off immediately after the precipitation, and that products of this kind are very liable to lose oxygen, one may with some probability give preference to the formula R_2O_5. Still it is a question which cannot be answered, whether these products are really peroxides, and not a kind of hydrate containing H_2O_2, in some manner analogous to the compounds of BaO_2, Na_2O_2, &c., with H_2O_2, which were discovered by Schöne.

Sulphide of Samarium.

Oxide of samarium was ignited in a current of hydrogen saturated with vapours of bisulphide of carbon. It was blackened with carbon, but its weight was very slightly increased, so that it may be concluded that the oxide of samarium is not attacked by bisulphide of carbon at a red-heat.

Fluoride of Samarium, $2SmFl_3+H_2O$.

Hydrofluoric acid produces with solutions of the salts of samarium a whitish, transparent, voluminous, and non-crystalline precipitate, which, on heating the solution, settles down as a heavy powder in a very fine state of division. The fluoride is not soluble in dilute acids.

I. 1·0888 grms. of the fluoride, dried at 110°, gave with sulphuric acid 1·5026 grms. Sm_23SO_4.

II. 2·0857 grms., dried at 100°, gave 2·8801 grms. Sm_23SO_4.

In per cent—

	I.	II.	Calculated.	
Sm.. ..	70·41	70·45	150	69·44
Fl	—	—	57	—
H_2O ..	—	—	9	—
			216	

It seems as if a little of the water were lost at 100°, as the analyses of two different preparations gave 1 per cent. Sm too much. This is also the case with the fluorides of the other cerium and yttrium metals.

* *Bull. Soc. Chim.*, xliii., p. 53, 1885.

Chloride of Samarium, $SmCl_3+6H_2O$.

This compound forms large, tabular, topaz-coloured crystals, easily soluble in water, and deliquescent in moist air.

The analyses of the salt, already published,* gave in per cent—

		Calculated.

Mean of the two determinations, 7·017.
Molecular volume, 28·7.

Bromide of Samarium, $SmBr_3+6H_2O$.

On evaporating over sulphuric acid a solution of oxide of samarium in hydrobromic acid, to the consistency of a syrup, large, well-developed, topaz-yellow crystals are deposited, which resemble in form crystals of gypsum. These crystals are very deliquescent, and when heated give off water and hydrobromic acid, even though mixed with excess of ammonium bromide. The whitish residue leaves on treatment with water brilliant micaceous crystals, probably of an oxybromide, which are slowly attacked by acids.

0·7634 grm. of the crystallised bromide, pressed between paper, gave 0·8540 grm. AgBr and 0·2662 grm. Sm_2O_3.

In per cent—

Chloroaurate of Samarium, $SmCl_4+AuCl_3+10H_2O$.

On slowly evaporating over oil of vitriol the mixed solutions of the chlorides of samarium and of gold, large, thick, and well-formed rhombic tablets of yellow colour are deposited when the solution becomes very concentrated. They are easily soluble and deliquescent.

0·4668 grm. was treated with zinc and a little dilute sulphuric acid. The remaining gold was washed with water, and finally with dilute hydrochloric acid. 0·1243 grm. Au and 0·5390 grm. AgCl were thus obtained.

0·7998 grm. was decomposed with sulphurous acid and evaporated to dryness. The residue, consisting of gold and samarium sulphate ($Sm_{23}SO_4$), weighed 0·5308 grm., and when treated with water left 0·2127 grm. Au.

CORRESPONDENCE.

THE INSTITUTE OF CHEMISTRY.

To the Editor of the Chemical News.

SIR,—In common no doubt with many other Fellows of the Institute of Chemistry, I have received a postcard from Mr. Wm. Thomson, the Honorary Secretary of the members of the Institute meeting at Manchester, and on their propositions I have the following comments to make :—

It appears that there are some chemists of high standing who are not members of the Institute whom the Institute desires to have on its list of Fellows. Of these there cannot be more than twenty or so. I conceive the right course to be that the Council should nominate them, and that the whole body of Fellows should vote on the nomination by means of ballotting papers. Such persons would probably refuse to be nominated were the condition numbered (2) in Mr. Thomson's letter to be insisted on.

To the second proposition in that paragraph, that existing members should have the option of becoming life-members on payment of £5 or £10, I for one consider that it would give old life-members like myself a claim on the Institute for repayment of a proportion of our life-membership outlay.

Those persons who desire to become Fellows, and who are not specially eminent in their profession, if their desire were a real one, could surely enter if the regulation regarding examination were modified as suggested in (3) of Mr. Thomson's letter. This relaxation of the rule might be temporary if it were thought expedient.—I am, &c.,

WILLIAM RAMSAY.

University College, Bristol,
January 16, 1886.

THE INSTITUTE OF CHEMISTRY.

To the Editor of the Chemical News.

SIR,—I have followed with great interest the discussion bearing upon the degrees of the Institute of Chemistry, and having carefully considered the object of the founding of the Institute, which was to raise the *status* of the chemist, and to give him a position equal to that conferred upon members of the other learned and scientific professions by their respective examining bodies.

I myself do not see how such an end can be obtained by admitting persons to the degrees of the Institute without examination. If this fatal policy is persisted in, it will end in diminishing the value of the degree, and render the endeavours to raise the profession of chemist, in the eyes of the public, abortive. I also think that such a step would be an act of great injustice to those members of the Institute who have obtained their degrees by examination.

I am confident that these opinions will be shared by a majority of the Members of the Institute of Chemistry.—I am, &c.,

D.

Liverpool, January 20, 1886.

CHEMICAL NOTICES FROM FOREIGN SOURCES.

NOTE.—All degrees of temperature are Centigrade unless otherwise expressed.

Moniteur Scientifique, Quesneville.
Vol. xvi., January, 1886.

Notes on the Literature of Explosives.—Prof. C. Munroe.—From the CHEMICAL NEWS.

Means of Removing Microbia from Water.—Dr. P. E. Frankland.—From the *Proceedings of Royal Society*.

Sensibility of Selenium and Sulphur Cells to Light.—Shelford Bidwell.—A paper read at the Aberdeen Meeting of the British Association.

International Exhibition of Inventions at London.—A continuation of the description of exhibits.

Nitrogen in the Soil.—From *Nature*.

Fixation of Nitrogen in Arable Soil.—H. Joulie.—An account of the experiments of M. Berthelot, described in the *Comptes Rendus* and already noticed.

Industrial Society of Mulhouse.—Session of Nov. 11, 1885.—C. Kœchlin announced that in continuation of his experiments on the oxidation of bases by tissues dyed in manganese bronze he has experimented on anthramine. This base, if treated like aniline or naphthylamine, gives merely greenish tints without interest. M. Bourcart called the attention of the committee to a crystalline sodium carbonate made at the works of Gaskell, Deacon, and Co. at Widnes, containing merely 1 mol. of water, being absolutely exempt from causticity and containing not a trace of alumina or of iron. C. Collin sent in a pamphlet by M. Lucien Benoist on fermentation in indigo vats and on the constitution of the theoretical vat. He sent in also a soluble black in competition for two prizes in the "Chemical Arts" department.

Patents taken in France relating to the Chemical Arts.—A list for the latter portion of October last.

Journal für Praktische Chemie.
New Series, Vol. xxxii., Part 10.

Nitrogenous Constituents of the Shoots of Pumpkins.—E. Schulze.—In the etiolated sprouts of pumpkins there are present glutamine, asparagine, leucine, tyrosine, vernine, xanthine bodies, ammoniacal salts, and nitrates. Most of these bodies are present both in the cotyledons and in the axial organs.

Contributions to the Knowledge of Fulminic Acid.—Louis Scholvien.—From a solution of sodium fulminate free fulminic acid is liberated by dilute sulphuric acid. Its existence in the free state was demonstrated by the preparation of its silver salts. Fulminic acid is unstable, and in its ethereal solution it is quickly decomposed into two acids agreeing with it in empirical composition. One of these acids, the isocyanuric, yields coloured salts with one, two, and three atoms of metal; if evaporated with hydrochloric acid it yields hydroxylamine and with potassa ammonia. It contains crystalline water, and on prolonged standing passes spontaneously into a second monobasic acid, β-isofulminuric acid, which is not affected by hydrochloric acid. The second product of decomposition, isocyanilic acid, yields unstable salts. It is not affected by hydrochloric acid, but boiling potash lye acts energetically, forming an acid isomeric with the uroxanic, which produces a deep violet potassium salt.

Action of Acetone upon Aniline.—Carl Beyer.—This paper is a reply to C. Engler and P. Riehm, who have republished some of Beyer's researches and taken up a subject the further examination of which he had reserved to himself. The editorial committee of the Berlin *Berichte*, in which Engler and Riehm's memoir had appeared, seems to have refused to insert Beyer's reply.

New Analytical Determination of Cadmium.—A. Carnot and M. Proromant.—From the *Comptes Rendus*.

Compounds of Gold Bromide with Phosphorus Bromide and Chloride.—L. Lindet.—From the *Comptes Rendus*.

Detection and Rapid Determination of Nitric Acid in Air and Water.—A. Grandval and H. Lajoux.—From *Comptes Rendus*.

Justus Liebig's Annalen der Chemie,
Vol. ccxxxi., Part 2.

Decomposition of Chlorine Water in Sunlight.—A. Popper.—The author has, in a former paper, shown the incorrectness of the ordinary supposition, that on the decomposition of an aqueous solution of chlorine on sunlight the only products are oxygen and hypochloric acid,

and has demonstrated the existence of a chlorate in the liquid after neutralisation. He has now examined the question whether the chloric acid was formed in the decomposed chlorine water, or took its rise afterwards on evaporating the neutralised solution by the decomposition of potassium hypochlorite. He finds that chloric acid must be present prior to neutralisation and evaporation.

Remarks on the foregoing Investigation.—L. Pebal.—In this thermo-chemical paper the author expresses the opinion that the difference in the behaviour of bromine and chlorine water depends on the different stability of the products of the decomposition.

Communications from the principal Chemical Laboratory of the University of Tübingen.—These comprise papers by A. Scheufelen, on iron compounds as transferrers of bromine; and by Lothar Meyer, on ferric chloride as a transferrer of iodine.

Communications from the Chemical Laboratory of the University of Jena.—These comprise a memoir by Adolf Israel, on propio-propionic-ethyl ether; and two papers by S. W. James, the one on the action of phosphorus pentachloride upon diethyl-acetacetic ether, and on the synthesis of acetacetic ether from cyanaceton.

Experiments on the Synthesis of Substances of the Uric Series.—R. Behrend.—The author has unsuccessfully attempted to remove 1 mol. of water from the compound described as hydroxy-xanthine. This body, on treatment with phosphorus pentachloride, yields methyl-hydroxy-xanthine, which is also prepared by heating ammonia with brom-methyl-uracil. The product is amido-methyl-uracil, the hydrochlorate of which, on treatment with potassium cyanate, yields methyl-hydroxy-xanthine.

Journal de Pharmacie et de Chemie.
Series 6, Vol. xiii., No. 1, January 1, 1886.

Direct Fixation of Atmospheric Nitrogen by certain Clayey Soils.—M. Berthelot.—Already noticed under the *Comptes Rendus*.

Acetophenone or Hypnone; a New Hypnotic Medicine.—S. Limousin.—A medical paper.

Hot Mineral Springs of Hamman-el-Lif, in Tunisia.—A. Barillé.—Of no chemical interest.

Falsification of Bees'-Wax.—A. Clarency.—The author first determines the specific gravity. He then boils a portion in a little water for the detection of mineral substances, starch, and turmeric. Finally he saponifies a portion with a solution of sodium carbonate for the recognition of fats, vegetable waxes, and paraffins.

Biedermann's Central Blatt fur Agrikultur Chemie.
Vol. xiv., Part 9.

Modifications and Effects of Water in Irrigation.—Prof. J. Kōnig and Dr. Boehmer.—An account of experiments made with the waters of the Rivers Durance, L'Isle, and Meurthe. The water was applied in some cases only for a few hours annually,—from 2¾ to 38,—and in others for 1178 to 2436 hours, or 101 days.

The Signification of the Hygroscopic Moisture of the Soil for Vegetation.—Dr. E. W. Hilgard.—The view formerly accepted, that the specific absorptive power of different soils for atmospheric moisture has a decided influence upon the prosperity of their vegetation, has latterly been pronounced erroneous by Riesler, Heinrich, Ad. Mayer, and Von Liebenberg. The author considers that the method adopted by these observers is not conclusive, and he gives instances incompatible with their views. He concludes that in a space fully saturated with watery vapour the absorption rises with the temperature up to 35°, the increase following apparently an arithmetical law. In a partially saturated atmosphere the absorption regularly decreases with an increasing temperature, Knop's law for this case not being universally applicable. A little below 15° the moisture seems equally distributed between the air and the soil.

The Influence of Different Manures on the Composition of the Ash of Tobacco.—W. H. Jordan.—The composition of the ash of tobacco is essentially modified by the different manures. The conclusion is drawn that tobacco should never be manured with common salt, kainite, or potassium chloride. Potash should be given as a sulphate or a carbonate.

Sugar as Food for Cattle.—B. Lawes.—From the *Journal of the Royal Agricultural Society of England.*

Analysis of American Cattle Foods.—E. H. Jenkins.—From the *Annual Report of the Connecticut Agricultural Experimental Station.*

Composition of the Total Milk of Short-Horn Cows, and of the Milk of Single Cows and Goats of Various Races.—Dr. P. Vieth.—The author, whose observations seem to have been made in England, gives the results of the analysis of the milk of a herd of three hundred short-horn cows, as made regularly for some years. The yearly means show for total solids respectively 13·0, 13·1, and 13·0 per cent. Cows of the Jersey, Guernsey, and Ayrshire breeds give, however, a higher mean as well as higher maxima.

Studies on the Albumens of Milk.—Dr. W. Engling.—The albumen of milk, as precipitated by boiling, was found rather richer in carbon and poorer in nitrogen than it is stated by Musro and Menozzi.

The same author has examined the albumen of colostrum, which has the same composition as the albumen of the blood.

Preservation of the Germinative Power of Seeds by Exclusion of Air, and by Desiccation at High Temperatures.—Prof. Wilhelm.—Seeds retain their germinative power longer if the air has been excluded. Still more favourable is the action of drying for two hours at 50°.

Assimilation-Products of the Leaves of Angiospermous Plants.—A. Meyer.—The author examines the question what chemical processes occur during the assimilation of the carbon of the atmospheric carbonic acid by the plant cell.

Root Tubercles of the Papilionaceæ.—F. Schindler.—These tubercles are not pathological outgrowths, but belong to the normal life of the plant.

Carbonates in Living Plants.—Berthelot and André.—From the *Comptes Rendus.*

Development of the Amarantaceæ.—Berthelot and André.—From the *Comptes Rendus.*

Analysis of the Leaves and Stems of Tobacco.—E. H. Jenkins.—From the "Annual Report of the Connecticut Agricultural Experimental Station."

Composition of the Ash of Strawberries—J. M. H. Munro.—From the CHEMICAL NEWS.

Yields of the Hop-Culture.—Dr. Emil Pott.—The author maintains that the production of the largest quantity of hops and that of the finest quality are two results not capable of being united.

Bulletin de la Société d'Encouragement pour l'Industrie Nationale. 3rd Série. Tome xii., October, 1885.

Report presented by M. de Luynes on behalf or the Committee of the Chemical Arts on the Processes of Appert Bros. for the Application of Compressed Air to Glass-Blowing.—This invention effects a purely mechanical object by purely mechanical means, and cannot therefore be legitimately considered as a "chemical art."

On the Utilisation of Sulphuric Acid which has served for purifying Petroleum or the Carbides of Coal-Tar.—A translation from the *Chemiker Zeitung.*

MISCELLANEOUS.

The Redwood Testimonial Fund.—A committee has been formed for the purpose of making a public recognition of Dr. Theophilus Redwood's services to pharmacy and the sciences connected therewith on the occasion of his retirement from the Professorship of Chemistry and Pharmacy to the Pharmaceutical Society, his appointment as Emeritus Professor, and his attainment (in March next) of the age of eighty years. This will involve the collection of a considerable sum of money, and in asking for support from pharmacists, medical men, and scientific chemists, the following sketch of Professor Redwood's career is submitted to show how largely such a claim is justified by the important services rendered by him to chemistry, more especially in its relations to medicine and pharmacy. In the year 1842 (just 44 years ago) Dr. Redwood was appointed Professor of Pharmacy to the Pharmaceutical Society, and in 1844 Director of the Chemical Laboratories. In 1846 he succeeded the late Professor Fownes as Professor of Chemistry. In these several capacities, in the first instance with Fownes, Pereira, and Thomson, he laboured earnestly and with marked success to promote the cause of scientific education in pharmacy, and at the present time the majority of practising pharmacists, many medical men, and not a few scientific chemists, owe much of their early scientific knowledge to his teaching. Professor Redwood's official connection with the Chemical Society dates from the year 1852, when he was appointed Secretary in conjunction with the late Sir Benjamin Brodie, a post which he held, subsequently with Professor Odling, until 1865, when he undertook the duties of Treasurer until 1870. In 1846 the Cavendish Society was founded, with Prof. Redwood as Secretary, a post which he retained during the whole period of its existence. Prof. Redwood's association with the British Pharmacopœia began in 1854, when he acted as Secretary to the Pharmacopœia Committee, which was appointed by the Pharmaceutical Society, at the suggestion of the Royal College of Physicians. The Committee held its sittings up to 1862, working from the year 1858 in conjunction with the Medical Council. In 1865 Professor Redwood was appointed by the Medical Council to edit a new edition of the British Pharmacopœia, which appeared in 1867, the edition with Addenda which appeared in 1874, and again the recent edition of 1885. Prof. Redwood's "Supplement to the Pharmacopœia" (8vo., 1118 pp.) has long been out of print, but is a book which had a world-wide reputation as an encyclopædia of Materia Medica. The first edition appeared in 1847, the second in 1848, the third and last in 1857. In 1840 Professor Redwood published a manual of "Practical Pharmacy," founded on that of Dr. Mohr. In 1872 an abridged edition of Pereira's "Materia Medica" was published, to which Professor Redwood contributed the chemical and pharmaceutical portion. In 1841 Professor Redwood was associated with the late Mr. Jacob Bell in the foundation of the *Pharmaceutical Journal*, of which he subsequently became editor, and continued in this capacity until 1870. Its pages bear witness to the extent of his contributions to pharmacy and to the sciences on which it depends. In 1856 Professor Redwood, in conjunction with Professors Graham and Hofmann, was appointed to report to the Chairman of the Board of Inland Revenue "On the Supply of Spirit Free from Duty." This led to the exemption of "Methylated Spirit" from Government duty, and thus accelerated the progress of many branches of industry as well as of scientific research. The foregoing sketch, although it includes only the chief features in Professor Redwood's career, shows how largely he has contributed to the development of the Materia Medica, how much purely honorary work he has done for the science of chemistry, and how, for more than half a century, he has devoted himself to the promotion of the scientific sides of Pharmacy, more particularly in connection with the organisation of the Pharmaceutical Society. Cheques, &c., crossed "London and Westminster Bank, Bloomsbury Branch," should be made payable to the "Redwood Testimonial Fund," and sent to the Honorary Secretary, Professor DUNSTAN, 17, Bloomsbury Square London, W.C.

MEETINGS FOR THE WEEK.

MONDAY, 25th.—London Institution, 5.
—— Medical, 8.30.
—— Society of Arts, 8. (Cantor Lectures). "Friction," by Prof. H. S. Hele Shaw.
TUESDAY, 26th.—Institution of Civil Engineers, 8.
—— Royal Medical and Chirurgical, 8 30.
—— Royal Institution, 3. "Naucratis," by R. Stuart Poole, LL.D.
—— Society of Arts, 8. "The Importance of a National Scheme of Emigration for the Best Interests of British Commerce," by Arnold White.
WEDNESDAY, 27th.—Society of Arts, 8. "Machinery in Mines," by Henry Davey, M.Inst.C.E.
—— Geological, 8.
THURSDAY, 28th.—Royal, 4.30.
—— London Institution 7.
—— Society of Arts, 8. "The Magnetism of Ships and the Mariner's Compass," by William Bo·tomley.
—— Royal Institution, 3. "Metals as affected by Small Quantities of Impurity," by Prof. W. Chandler Roberts-Austen, F.R.S.
FRIDAY, 29th.—Royal Institution, 9. "Capillary Attraction," by Sir William Thomson, D.C.L., LL.D., F.R.S.
SATURDAY, 30th.—Royal Institution, 3. "The History of Volcanic Action in the British Isles," by Archibald Geikie, LL.D., F.R.S.

Second Edition, re-written and greatly enlarged, with 37 Illustrations on Wood.

8vo., Price 24s.

SELECT METHODS IN CHEMICAL ANALYSIS
(CHIEFLY INORGANIC).

BY

WILLIAM CROOKES, F.R.S., V.P.C.S.,
EDITOR OF "THE CHEMICAL NEWS."

LONDON: LONGMANS, GREEN, & CO.

CITY AND GUILDS OF LONDON INSTITUTE.
CENTRAL INSTITUTION, EXHIBITION ROAD, S.W.

A Course of 12 Lectures on Methods of Determining the Nature of Complex CARBON COMPOUNDS will be given by PROFESSOR ARMSTRONG, F.R.S., on Monday, January 25th, and on the following Mondays, at 5 p.m. Fee for the course, Ten Shillings.

Registered Teachers of the Institute will be admitted to this Course without payment of Fees.

PHILIP MAGNUS, Secretary and Director.

PATENTS.

W. P. THOMPSON, C.E., F. Inst., P.A. (M.S.C.I.),
Agent for Procuring British and Foreign Patents,
6, LORD STREET, LIVERPOOL.
MAIN SPECIALITY—CHEMICAL.
Private Laboratory kept for Scientific Research. Principal Chemical Assistant, H. JONES, F.C.S.
Manual of Instructions Gratis.
LONDON OFFICE: W. P. THOMPSON & BOULT, 323, HIGH HOLBORN

Water-Glass, or Soluble Silicates of Soda and Potash, in large or small quantities, and either solid or in solution, at ROBERT RUMNEY'S, Ardwick Chemical Works, Manchester.

FOR SALE.
COMPLETE SET (unbound and uncut) of
THE CHEMICAL GAZETTE,
A Journal of Practical Chemistry.
17 Volumes; from November, 1842, to December, 1859.

Address, "Publisher," CHEMICAL NEWS Office, Boy Court, Ludgate Hill, London, E.C.

Vol. LIII. No. 1366.

ON THE DETERMINATION OF OXIDE OF IRON AND ALUMINA IN PHOSPHATES.

By BERNARD DYER, F.C.S., F.I.C.

The following is an accurate and satisfactory method of determining oxide of iron and alumina in phosphates:—

Two grms. of the powdered phosphate are digested in hydrochloric acid and evaporated to dryness in a water-bath, and the residue is taken up with a little more hydrochloric acid. The sand being filtered off, the filtrate, diluted to about 100 to 150 c.c., is then precipitated with a considerable excess of acetate of ammonia, *in the cold*, a slight excess of acetic acid being added. The gelatinous precipitate is allowed to subside for some time (preferably over-night), and the supernatant liquor is poured carefully off through a filter. The precipitate is then washed again by decantation with cold water, transferred to the filter, and then washed two or three times with hot water. It is then dried, burnt, and weighed.

This "acetate of ammonia precipitate," thus weighed, contains phosphoric acid, oxide of iron, alumina, and (usually) some lime.

After weighing it is dissolved in hydrochloric acid,—a very easy and rapid operation if *concentrated* acid be used—a sufficiency of citric acid is added to keep the oxide of iron and alumina in solution, the solution is neutralised with ammonia, a slight excess of acetic acid is added, and any lime present is precipitated with oxalate of ammonia, filtered off, and weighed in the usual way.

The phosphoric acid in the filtrate is then precipitated in the usual way, as ammonio-magnesian phosphate, and weighed as pyrophosphate. The ammoniacal filtrate is treated with sulphide of ammonium, and after standing a sufficient length of time the ferrous sulphide is filtered off, washed, oxidised with nitric acid, precipitated with ammonia, and the iron is weighed in the form of oxide.

The combined weight of the lime, the phosphoric acid, and the oxide of iron, being deducted from the weight of the "acetate of ammonia precipitate," the difference necessarily gives the weight of the alumina,—though of course, if it be wished, this may be directly obtained by the evaporation of the filtrate from the ferrous sulphide, its incineration, fusion with bisulphate of potash, and subsequent solution and precipitation with ammonia. This separate determination, however, of the alumina is wholly unnecessary.

In the foregoing method there is, as far as I know, no originality whatever, but I have been led to publish it by the letter which appeared in the Chemical News (vol. liii., p. 35), which seems to show, if its statements are correct, that some chemists are certainly at fault in this matter.

It is, I believe, customary with some chemists to weigh the "acetate of ammonia precipitate" and assume that it consists of a simple mixture of ferric and aluminic orthophosphates. The oxide of iron being volumetrically determined, is calculated into $Fe_2P_2O_8$, and it is then assumed that the remainder of the precipitate is $Al_2P_2O_8$, and the alumina is deduced from this assumption. As a matter of fact it is very rarely that the "acetate of ammonia precipitate" has this composition, being generally of a more basic nature; and, moreover, it is rarely that lime is absent, it being exceedingly difficult to obtain phosphates of iron and alumina free from lime when precipitating from a solution containing an overwhelming excess of this substance.

The method may appear tedious, though it is less so in practice than it appears to be on paper. It certainly entails a day longer than more rough and ready methods, but it is the only mode of procedure I am at present acquainted with that gives accurate results, and the only one that I should myself consider admissible as the basis of a certificate.

It may have been noticed that at the outset I mentioned hydrochloric acid as a solvent; and this suggests a point that may be productive, and often *is* productive, of analytical discrepancies. Certain phosphates, as is well known, contain iron pyrites. It is not fair to regard the iron in pyrites as oxide of iron; and hydrochloric acid has the advantage of not dissolving up the pyrites, but leaving it amongst the siliceous matter. The solution contains only the iron existing as oxide (or phosphate). The iron present as pyrites may be determined by igniting the sand and treating it with hydrochloric acid, in which the iron is then of course readily soluble, and may be easily determined.

But no analysis of a phosphate should include, in the term "oxide of iron," the iron that is present as pyrites.

If nitric acid be added to the original solvent the *whole* of the iron passes into solution, and is all included as "oxide," unless, of course, a separate determination of pyrites be made, and a deduction made for it.

If the pyrites is not shown separately in the analysis of a phosphate which contains it (such as the Carolina river phosphates), the statement ought to be, to avoid misunderstanding, either—

"Oxide of iron (exclusive of iron as pyrites), x·x per cent."

or—

"Oxide of iron (inclusive of iron existing as pyrites) x·x per cent."

But it is far better to state the pyrites and oxide of iron separately, that there may be no confusion.

This point is important not merely for avoiding discrepancies, but as materially affecting the apparent value of a phosphate; for iron pyrites in a phosphate is by no means the objectionable constituent that oxide of iron is.

DETECTION AND ESTIMATION OF THALLIUM IN PRESENCE OF LEAD.

By EMIL. A. WERNER (Dublin).

The separation of thallium from lead, and its estimation when occurring in solution with the latter metal, cannot be effected by any of the hitherto known methods without the previous separation of the lead, by precipitation as sulphate or otherwise; and, indeed, without the spectroscope the simple detection of small quantities of thallium in presence of lead is almost impossible without the previous separation of the last-mentioned metal. Having occasion to work up some laboratory residues containing thallium mixed with large quantities of lead, &c., the following method was found to work admirably, without necessitating beforehand the separation of the inexpensive lead:—

If a solution of sodic thiosulphate be added to a neutral or alkaline solution of a lead salt a white precipitate of lead thiosulphate is first formed, which dissolves on adding excess of the precipitant, a complex double salt of lead and sodium thiosulphate being probably formed, each molecule of PbS_2O_3 requiring 10 molecules of $Na_2S_2O_3$ before complete solution is effected. From such a solution lead is not precipitated by the majority of the reagents for that metal, such as sulphates, chlorides,

iodides,* &c. If a solution of sodic thiosulphate be added to a neutral solution of a thallium salt no precipitate is produced, and in such a solution containing excess of $Na_2S_2O_3$, KI produces the characteristic yellow precipitate of thallious iodide.† By taking advantage of this negative reaction of thallium, its separation from lead in a single operation is readily effected. To the liquid containing both metals in solution (if acid the solution must be carefully neutralised beforehand) sodic thiosulphate is added until the precipitate first formed is entirely re-dissolved. Potassic iodide is then added until it ceases to produce a yellow precipitate. The thallium is thereby wholly removed, and the pure metal can be readily obtained from the washed and dried precipitate by fusion with potassic cyanide.

As a qualitative test for the detection of minute traces of thallium in presence of large quantities of lead this method rivals almost the spectroscope in delicacy. By means of it, 1 part of thallium in 653,600 parts of solution, and mixed with over 5000 times its weight of lead, can be easily detected.

INSOLUBILITY OF BARIUM CHLORIDE IN PRESENCE OF LITHIUM CHLORIDE.

By CARTER N. DRAPER.

In the examination of some samples of commercial lithium carbonate for sulphuric acid, I observed that on the addition of barium chloride to the neutral solution of the chloride a considerable crystalline precipitate was formed. That a double salt might have been produced seemed, under the circumstances, to have been probable; but repeated crystallisation and examination by the spectroscope of the finally-resulting crystals showed so definitely that this was not the case that a quantitative examination became unnecessary. The crystalline precipitate is simply barium chloride insoluble in a concentrated solution of lithium chloride. The well-recognised insolubility of barium salts in concentrated inorganic acids would here appear to be intensified by the presence of a base, with the low atomicity of lithium, for a like result is obtained, though in a much less marked degree, when, instead of lithium chloride, the chlorides of sodium, potassium, or calcium are employed.

The phenomenon appears to be one of dissociation; the more soluble salt withdrawing from the less soluble the water necessary to retain it in solution.

ANALYSES OF SOME IRON ORES.

By J. CUTHBERT WELCH.

I. *Hæmatite.*

1. A stalactitic, compact specimen from Arendal, in Norway. It was of a very dark steel-grey colour, and possessed a high metallic lustre. Streak very dark brownish red. Rather brittle, yielding, when broken, a surface furrowed in one direction. Very feebly magnetic. Three determinations of its specific gravity, at 17° C., gave 5·266, 5·258, and 5·261; mean = 5·260. Metallic iron = 69·28 per cent.

Data.

Iron—
0·25 grm. required 17·32 c.c. potassium bichromate.
Hygros. water—
5 grms. gave 0·0163 grm. hygroscopic water.
Sulphur—
5 grms. gave 0·1165 grm. barium sulphate.
Phosphorus—
4 grms. gave 0·0023 grm. magnesium pyrophosphate.
Silica—
5 grms. gave 0·0103 grm. silica.

Percentage.

	Original.	Dried at 100° C.
Fe_2O_3	98 972	99·296

2. This was given to me as a fair sample of the better class of ore in the district of Penrhyn, North Wales. It varied from reddish brown to nearly black in colour, and was either botryoidal or inclining to granular in form; in the former case being rather brittle and shiny, with a submetallic lustre; in the latter hard, friable, and dull. Streak reddish brown. Fracture uneven and rough. Two determinations of its specific gravity gave 4·59 and 4·536; mean = 4·563. Metallic iron = 65·399 per cent.

Data.

Iron—
0·5 grm. required 32·7 c.c. potassium bichromate.
Hygros. water—
5 grms. gave 0·0658 grm. hygroscopic water.
Combined water—
5 grms. gave 0·0260 grm. combined water.
Sulphur—
5 grms. gave 0·0131 grm. barium sulphate.
Magnesia—
5 grms. gave 0·0012 grm. magnesium pyrophosphate.
Lime—
5 grms. gave 0·0517 grm. calcium sulphate.
Silica—
5 grms. gave 0·1636 grm. silica.
Arsenic—
5 grms. gave 0·0119 grm. magnesium pyroarsenate.
Alumina—
5 grms. gave 0·0163 grm. alumina.

Percentage.

	Original.	Dried at 100° C.

3. From Ulverstone, Cumberland. Colour ochreous-red. Earthy and friable. Streak of a rather lighter shade than the colour. Fracture subconchoidal to uneven. Finely speckled in places with a white substance which appeared to be at times quartz, at others calcite. The portion analysed was picked as free from these spots as possible. Three determinations of its specific gravity gave

* Lead iodide, being readily soluble in $Na_2S_2O_3$ solution, the addition of KI produces no change in the above solution. If, however, a solution of iodine in KI be added a precipitate of PbI_2 is formed, which at first re-dissolves on shaking, but afterwards becomes permanent, though a considerable quantity of unoxidised thiosulphate still remains in solution.

† Thallious iodide is somewhat soluble in an excess of $Na_2S_2O_3$, but in presence of a lead salt is practically insoluble.

4·638, 4·630, and 4·256; mean = 4·508. Metallic iron = 60·2 per cent.

Data.

Iron—
0·25 grm. required 15·05 c.c. potassium bichromate.
Hygros. water—
5 grms. gave 0·0363 grm. hygroscopic water.
Combined water—
5 grms. gave 0·0032 grm. combined water.
Sulphur—
5 grms. gave 0·2709 grm. barium sulphate.
Phosphorus—
4 grms. gave 0·0973 grm. magnesium pyrophosphate.
Lime—
5 grms. gave 0·0786 grm. calcium sulphate.
Silica—
5 grms. gave 0·4626 grm. silica.
Lead—
6 grms. gave 0·330 grm. lead sulphate.
Copper—
6 grms. gave 0·0083 grm. copper subsulphide.

(To be continued).

DETERMINATION OF SMALL QUANTITIES OF SODIUM CHLORIDE IN PRESENCE OF POTASSIUM CHLORIDE.

By F. RÖTTGER and H. PRECHT.

To determine with accuracy small proportions of sodium chloride in an excess of potassium chloride the authors first sought for a method of concentrating the sodium chloride from a large quantity of the potassium salt, so as then to be able to submit the resulting product to analysis. To this end they tried:—

1. Precipitation of potassium chloride as acid potassium tartrate.
2. Conversion of the sodium chloride into sodium hydroxide by means of potassium hydroxide and removal of the former by lixiviation with absolute alcohol.
3. Direct extraction of the sodium chloride by means of dilute alcohol.

The last method is the best; it depends on the fact that sodium chloride is more soluble in alcohol at 90 to 95 per cent than potassium chloride; 20 grms. of the mixed salts containing 0·1 grm. NaCl were covered with 40 grms. alcohol at 90 per cent, digested for half an hour, filtered, washed with alcohol of the same strength and in the filtrate, weighed after evaporation and gentle ignition; the potassium chloride was determined in the usual manner with platinum chloride, and the sodium chloride is taken as difference. It is necessary to add to the mixture of alcohol and saline mixture ½ c.c. of a 10 per cent solution of potassium carbonate in order to precipitate any magnesium chloride as carbonate.—*Berichte Chem. Gesellschaft.*

AN ABBREVIATED METHOD OF DETERMINING PHOSPHORIC ACID BY THE MOLYBDENUM PROCESS.

By M. MEINECKE.

If the well-known yellow precipitate produced on throwing down phosphoric acid with the ammonium molybdate is heated to 400° to 500° there remains molybdenum phosphomolybdate as a black residue. This compound in certain conditions is very stable, and as it is only very slightly hygroscopic it can be weighed with safety. Meinecke finds that its composition is constant (4·018 per cent P_2O_5), and proposes this process as a substitute for the magnesia one in the analysis of substances containing phosphoric acid whether in small or large proportion.

In effecting the determination the nitric solution of the phosphate obtained in the ordinary manner and containing from 20 to 25 per cent of ammonium nitrate is precipitated with molybdic solution at 50° to 60°, stirring meanwhile, and the precipitate is then set aside to settle for some hours without any further application of heat. This departure from the usual procedure is essential in order that the phosphoric and molybdic acid in the precipitate may have the fixed molecular proportion of 1 : 24. After settling for two to three hours the precipitate is collected on a filter, washed first with a faintly acid 20 per cent solution of ammonium nitrate until ten drops react neither with sulphuretted hydrogen, nor, in case of solutions rich in iron, with potassium ferrocyanide. The washing is completed with cold water, or, to expedite the drying, once with water, once with alcohol, and once with ether. The dried precipitate is detached as completely as possible from the filter and placed in the flat platinum capsule. The filter is then incinerated separately in a platinum crucible at the lowest possible temperature, the ash added to the main precipitate in the capsule, which is covered with platinum foil and placed over an "Iserlohn" (Mastes') burner with triple air current at a temperature

just sufficient for a slow decomposition indicated by the blackening of the precipitate. In one quarter hour the precipitate becomes uniformly black and may be weighed when cold.—*Repertorium Anal. Chemie* (vol. v., p. 153).

PROCEEDINGS OF SOCIETIES.

CHEMICAL SOCIETY.

Thursday, January 21st, 1885.

Dr. HUGO MÜLLER, F.R.S., President, in the Chair.

MESSRS. Charles Langert, W. J. Cousins, W. Watson Will, and G. H. Bailey were formally admitted Fellows of the Society.

Certificates were read for the first time in favour of Messrs. Caleb Ferrey, M.B., C.M., B.Sc., Mainhead, Bondi, Sydney, N.S.W.; Francis W. Leeds, Glenfield, 69, Highbury New Park, N.; Arthur Percy Hoskins, 58, Wakehurst Road, New Wandsworth, S.W.; James Galbraith Ross, 14, Argyle Place, Grange, Edinburgh; Arthur John Starey, 8, Duncombe Road, Hornsey Rise, N.; Sidney Williamson, Fairholme, Esher, Surrey; William T. Wright, 15, Victoria Road, Bromhall Park, Sheffield; Brougham Young, Home Lyn, Woodberry Down, London.

The following papers were read :—

1. "*The Influence of Silicon on the Properties of Cast-Iron.*" Part III. By THOMAS TURNER.

The paper is a continuation of those recently published by the author on the same subject (*Trans.*, xlvii., 577, 902). It is shown that the previous results strongly support the author's conclusions, although opposite opinions have been generally held.

The Woolwich Report, "Cast-Iron Experiments, 1858," is considered in detail. This Report included the chemical analyses and mechanical tests of 70 specimens of British cast-iron. The author classifies these irons according to the amount of phosphorus present, and in different tables considers every specimen mentioned in the Report. Some of the more important results are as follows :—

1. Only eight specimens were mentioned as being "too hard to turn;" seven of these contained under 0·9 per cent of silicon, while the eighth was rich in phosphorus and sulphur. These facts strongly support the author's conclusion that a softening effect is produced by a suitable proportion of silicon.

2. The six best specimens mentioned in the Report contained on an average 1·393 per cent of silicon, while the author, from his own experiments, recommended about 1·4 per cent. The six specimens lowest in silicon are of intermediate quality, while the six specimens highest in silicon are of inferior quality. These results support the author's view that a suitable proportion of silicon is beneficial.

3. When the specimens are classified according to their proportion of phosphorus, and arranged in tables in order of silicon present, a gradual improvement is noticed as the silicon increases until a certain point is reached, beyond which point the metal deteriorates in quality. In one table, however (0·2—0·4 per cent of phosphorus), no such regularity is observed: this is due to the small variations in silicon and the large alterations in the proportion of other elements present.

4. That the maximum points are as follows :—(See Table next column).

With under 0·2 per cent phosphorus	1·88 p.c. Si
Between 0·4 and 0·6 per cent phosphorus	1·21 ,,
Between 0·6 and 1·0 per cent phosphorus	1·41 ,,
Over 1 per cent phosphorus	1·57 ,,
English irons in the Appendix	1·03 ,,
Foreign irons in the Appendix	1·33 ,,
Mean	1·405 ,,

The author also refers in detail to Sir William Fairbairn's experiments of 1853 on the influence of re-melting on the mechanical properties of cast-iron. It is shown that the results obtained may be entirely explained by the chemical changes which took place; and that when regarded in this light they illustrate the influence of silicon on cast-iron very much in the same way as did the results previously published by the author.

DISCUSSION.

Prof. UNWIN said that Mr. Turner had done a service in removing the popular prejudice that silicon is a very injurious constituent of cast-iron. This prejudice arose a long time ago, apparently from the difficulty experienced in smelting very rich iron ores containing much silica. Thus the Turkish Government in 1844 wished to utilise an exceedingly rich ore (magnetic ore containing 12 per cent silica) found at Samakoff, but could not smelt it, and the difficulty was attributed to the silica. Again, about 1853 attempts were made to improve cast-iron guns, and Mr. Cochrane advised the use of Nova Scotia iron. This was tried at Woolwich, but the Chemical Department there refused to sanction its use on the ground that it contained too much silicon, notwithstanding that Mr. Fairbairn's mechanical tests were in its favour.

Prof. UNWIN exhibited specimens of some of the bars produced in Mr. Fairbairn's 1853 experiments in the re-melting of iron, and he stated that the iron was re-melted in a brass furnace, not a cupola. From the analyses quoted of the bars tested in these experiments it appeared that the only chemical change which occurred in re-melting was the change in the amount of silicon, which therefore seemed to be the sole cause of the variation in strength. But this was a fallacy: the methods of determining carbon in those days were faulty, and no distinction was drawn between graphitic and combined carbon. The change in properties on re-melting was always attributed chiefly to the change from graphitic to combined carbon. Mr. Turner stated that he had found exceptional values of the modulus of elasticity. Now the determination of the modulus of elasticity was so difficult that hardly any measurement is to be trusted unless the measurements are made on suitable bars under suitable conditions; frequently the bars used are far too short. He was not prepared to agree that because a certain proportion of silicon was present, therefore the iron was good; and it was essential to bear in mind that in cast-iron we want not strength so much as certain working qualities; mere crushing strength was of very little importance.

As supporting Mr. Turner's views, Mr. POCHIN quoted an instance of an iron containing some amount of silicon being accepted by a manufacturer of very small castings as suitable in place of one with less which had been complained of as unsuitable on the ground that it contained too much silicon. He suggested that some of the discrepancies in analyses referred to by the author might really be due to difference in composition; different parts of one and the same pig or steel ingot often differ very much in composition. He had recently had occasion to notice great differences in quality in the two ends of steel sleepers, the one withstanding all tests, the other breaking readily.

Mr. TURNER, in reply, said that he did not contend that a large proportion of silicon was good, but that when present in suitable proportion it improved the quality of the iron. No doubt the conversion of graphitic into combined carbon was a most important change, but the extent to which this took place probably in some way depended on the amount of silicon present; he had shown in a previous paper that grey cast-iron can be made from white by addition of silicon. He did not think that the serious

discrepancies which he had called attention to could be explained in the manner suggested by Mr. Pochin.

2. "*The Chemical Action of Pure Cultivations of* Bacterium aceti." By Adrian J. Brown.

After referring to the work of Pasteur and others on acetic fermentation, the author describes his method of working and the means used for obtaining pure cultivations of *Bacterium aceti*. He then treats of the mode of growth and morphology of the organism. The different cell-forms observed agree with the drawings of *B. aceti* by Hansen and Zopf. The ferment is strictly ærobic.

After showing that *B. aceti* oxidises ethylic alcohol to acetic acid, and that the acetic acid so formed is subsequently destroyed by the ferment, its action on other alcohols of the same series is studied. Normal propylic alcohol is freely oxidised to propionic acid, but methylic alcohol is not acted upon. Isoprimary butylic alcohol and amylic alcohol are also not attacked.

The action of *B. aceti* on certain carbohydrates is then described. Dextrose is freely acted on by the ferment; no alcohol or volatile acid is formed during the fermentation, the sole product being gluconic acid, the relation of which to dextrose is exhibited in the formulæ:—

Dextrose—
$CH_2(OH)\cdot CH(OH)\cdot CH(OH)\cdot CH(OH)\cdot CH(OH)\cdot COH.$

Gluconic acid—
$CH_2(OH)\cdot CH(OH)\cdot CH(OH)\cdot CH(OH)\cdot CH(OH)\cdot COOH.$

Cane-sugar is unaffected by *B. aceti*, even when the organism is made to grow freely in a solution containing it. This is true also of milk-sugar and starch.

Mannitol is shown to be completely acted upon by *B. aceti*, the main product being lævulose. A small proportion of a body possessing a cupric reducing power, but no action on polarised light, is also simultaneously formed. No acid is formed, the lævulose produced not being further acted on by *B. aceti*. Lævulose prepared from inulin is also not oxidised by the ferment, thus indicating a marked difference in the constitution of dextrose and lævulose. Using Kiliani's formula for lævulose, its relation to mannitol is shown by the formulæ:—

Mannitol—
$CH_2(OH)\cdot CH(OH)\cdot CH(OH)\cdot CH(OH)\cdot CH(OH)\cdot CH_2(OH)$

Lævulose—
$CH_2(OH)\cdot CH(OH)\cdot CO\cdot CH(OH)\cdot CH(OH)\cdot CH_2(OH).$

As mannitol may be formed from dextrose by the action of sodium amalgam, the oxidation of mannitol by *B. aceti* appears to afford a means of converting dextrose into lævulose.

Discussion.

The President remarked that the study of the effects produced by various organisms presents an enormous field for research; the results obtained by Fitz had already shown this. The experiments were also of interest as bearing on the examination of antiseptics, and pointed to the importance of ascertaining their effect upon a variety of organisms, as a given antiseptic might affect one kind and not another.

Dr. Armstrong said that Mr. Brown's results appeared to him to throw some light on the remarkable transformations undergone by the carbohydrates in plants and animals. It is well known that in some cases starch wanders from the leaves where it has been formed and is elsewhere again deposited as starch, as in the potato for example; that in the sugar-beet it becomes cane-sugar, and in the dahlia and artichoke, inulin; and that sometimes in animals it becomes milk-sugar. No clue has hitherto been obtained to these and similar changes. The conversion of mannitol into lævulose, however, indicates a possible mode of obtaining cane-sugar from starch, as it is unquestionable that a change such as that of starch into dextrose and then into mannitol takes place within the plant, and that individual cells may act upon the mannitol in the same way as *B. aceti* does, forming lævulose, which might then enter into reaction with dextrose. As regards the difference in behaviour of various carbohydrates, he thought that caution must be observed in reasoning from the formulæ ordinarily employed; probably even the simplest carbohydrates exist in solution as complex aggregates of several C_6 groups, and their behaviour much depends on the composition of these aggregates. Mr. Brown's observations were also of value as throwing light on the phenomena of fermentation. He (Dr. Armstrong) had long thought that fermentation took place in consequence of a something contained within the ferment organism attaching itself to the molecule of the fermented substance; action thereupon set in at this point of attachment, and hydrolysis taking place the molecule was ultimately broken up: the function of ferments was, in fact, to localise the action, whether of water alone, or of water and atmospheric oxygen. Mr. Brown's observations on mannitol clearly proved that the organism exercised a selective influence.

3. "*A Method of Separating and Estimating Zirconium.*" By G. H. Bailey, D.Sc., Ph.D.

When a solution of zirconia in dilute sulphuric acid is treated with excess of hydrogen peroxide, a white bulky precipitate is obtained consisting of an oxide of zirconium of the formula Zr_2O_5. This oxide seems to be possessed of very well-defined characters, and moreover the precipitation is a complete one. It is suggested that the reaction may be utilised as a means of obtaining pure compounds of zirconium, of separating zirconium—especially where it occurs in small quantities in minerals, and in quantitatively determining this element.

4. "*Notes on an Analysis of Koppite.*" By G. H. Bailey, D.Sc., Ph.D.

The following are the author's results:—

		Knop and Rammelsberg.
Nb_2O_5	61·4	62·18
TiO_2	0·72	—
ThO_2	—	3·0
ZrO_2	3·39	—
Ce, La, Di oxides ..	6·89	6·69
FeO	3·01	1·80
CaO	16·61	16·00
MgO	1·62	0·4
Na	3·58	5·58
K	0·36	4·23
F	Not estimated	6·23

Discussion.

The President enquired how the titanium had been separated from niobium; he was not aware that any method had yet been devised. The discovery of titanium in the mineral was in itself an interesting fact; had the author taken the precaution of excluding Dysanalyte?

Dr. Bailey, in reply, said that the titanium was estimated in presence of the niobium by a colorimetric method, by means of hydrogen peroxide; the crystals were very carefully selected, and only the octahedral ones were analysed.

5. "*The Monobromophthalic Acids.*" By G. Stallard.

Guareschi and Meldola have both assumed that the bromophthalic acid melting at 175° is the 1 : 2 : 4 modification, attributing the alternative formula—

COOH : COOH : Br = 1 : 2 : 3

to the acid melting at 139°. Guareschi obtained the acid of higher melting point by oxidising the bromonitronaphthalene produced on brominating nitronaphthalene. The author, however, finds that α-bromonaphthalene is produced on eliminating the NO_2 group from Guareschi's bromonitronaphthalene; and that it yields γ-dibromonaphthalene (melting at 130°) on displacing the NO_2 group by Br. Hence he infers that the bromophthalic acid melting at 175° is the 1 : 2 : 3 modification; and he points out that this view is favoured by the fact that,

according to Krüger, the melting-point of the anhydride of the 1 : 2 : 3 chlorophthalic acid is much higher than that of the 1 : 2 : 4 modification. This conclusion, however, does not harmonise with Meldola's view of the constitution of the dibromonaphthylamine which he obtained from bromo-β-naphthylamine from Liebermann's bromonitronaphthalene.

6. "*Benzoylacetic Acid and some of its Derivatives.*" Part IV. By W. H. PERKIN, Jun., Ph.D., and A. CALMAN, Ph.D.

In the hope that methylic benzoylacetate might prove to be a crystalline substance, the authors have prepared it from methylic phenylpropiolate and sulphuric acid; but they could not obtain it otherwise than as an oil, and several of its derivatives were also found to be oils.

Ethylic methylbenzoylacetate is described. PCl_5 converts it into ethylic α-methyl-β-chlorocinnamate,—

$$C_6H_5{\cdot}CCl : CMe{\cdot}COOEt.$$

By the action of sodium amalgam on its alcoholic solution, α-methyl-β-hydroxyphenylpropionic acid is produced. Ethylic propylbenzoylacetate is next considered, and its conversion into butylphenylketone by the action of dilute alcoholic potash is described; it yields ethylic α-propyl-β-chlorocinnamate on treatment with PCl_5. An account of ethylic isopropylbenzoylacetate and isobutylbenzoylacetate and of the corresponding ketones is then given.

The authors have further studied ethylic furfurandicarboxylate obtained by heating ethylic dibenzoylsuccinate with sulphuric acid.

7. "*Mercury Sulphites and the Constitution of Sulphites.*" By EDWARD DIVERS, M.D., F.R.S., and TETSUKICHI SHIMIDZU, M.E.

In formation, composition, and reactions the mercury sulphites, according to the authors, are not ordinary salts, and supply many facts serving for the determination of the constitution of non-saturated oxygenous salts. The mercuric radicle, Hg, takes up and preserves a non-oxylic relation to sulphuryl with an energy comparable to that it exerts in its cyanide and iodide; this is the central conception in the chemistry of the mercury sulphites, and they are of opinion that without it all the peculiarities of these salts stand unexplained.

The paper is of great length; the salts which are described and discussed, and the formulæ attributed to them, are as follows:—

Mercuric sodium sulphite .. $Hg\langle^{SO_2{\cdot}ONa}_{SO_2{\cdot}ONa}\rangle{\cdot}OH_2$

Mercuric hydrogen sulphite (known only in solution) $Hg\langle^{SO_2{\cdot}OH}_{SO_2{\cdot}OH}$

Mercuric oxysulphite.. .. $Hg\langle^{SO_2{\cdot}OHgO}_{SO_2{\cdot}OHgO}\rangle Hg{\cdot}OH_2$

Mercuric mercurous or mercurosic sulphite .. .. $Hg\langle^{SO_2{\cdot}O}_{SO_2{\cdot}O}\rangle Hg_2{\cdot}4OH_2$

Mercuric hypomercurous or hypomercurosic sulphite $Hg\langle^{SO_2{\cdot}O}_{SO_2{\cdot}O}\rangle Hg_3{\cdot}OH_2$

Only the first and third of these have been previously described. Normal mercuric and mercurous sulphites do not appear to be capable of existing.

Among the conclusions arrived at are the following:—In reduction by sulphurous acid, the acid is not as such or directly oxidised by the metallic salts reduced, but a sulphite is formed through changes in which reduction afterwards follows. Either, as in the case of mercurosic sulphite, a further quantity of the sulphurous acid or alkali sulphite resolves the salt into a double salt of part of the metal: the free metal, *e.g.*, mercurosic sulphite becomes mercuric hydrogen sulphite and mercury; or the sulphite suffers hydrolysis into metal and sulphuric acid.

Mercury and silver sulphites resemble organic sulphites (sulphonates) in undergoing hydrolysis into sulphuric acid and basic radicle, and in not oxidising in the air. The contrast they afford in this respect to most other metallic sulphites is good evidence of sulphites having a hemihaloid constitution. Hydrolysis may in fact serve as a test of the constitution of an oxygenous salt: if the salt suffer hydrolysis into acid and metal the salt is partly haloid; while if it yield acid and basic oxide it is wholly oxylic.

Sulphites are like haloid salts and unlike oxylic salts in the property which some of them display of parting with some of their chlorous radicle. Mercuric sulphite becomes mercurosic sulphite, much as manganic chloride becomes manganous chloride and cupric iodide or cyanide becomes cuprous; mercury and silver sulphites become metal and acid radicle, much as gold chlorides become gold and chlorine. There is a difference in the cases, but this is accounted for by the sulphites being hemi-oxylic salts,—therefore requiring water to effect their decomposition. Sulphites are also like haloid salts in the considerable insolubility of their silver and mercury compounds in nitric acid; and they resemble iodides and cyanides, inasmuch as the double mercury and silver salts are stable and not decomposed by free alkalies.

8. "*Potassium Chlorate.*" By FRANK L. TEED, D.Sc.

The author in a previous paper arrived at the conclusion that the decomposition of potassium chlorate by heat may be represented by the equation—

$$10KClO_3 = 6KClO_4 + 4KCl + 3O_2.$$

He has continued his experiments, and finds that when the salt is very gently heated the decomposition more nearly approximates to that indicated by the equation $22KClO_3 = 14KClO_4 + 8KCl + 5O_2$, the majority of his results falling within the limits calculated from these two equations.

As bearing on the subject, the decomposition of potassium perchlorate by heat was investigated; it appears that in the earlier stages potassium chlorate is formed, but this disappears again long before the complete decomposition of the perchlorate is effected.

He finds that when the perchlorate is heated with manganese binoxide, it decomposes apparently without any chlorate being formed.

Some numbers obtained by Baudrimont, which had an apparent similarity to his own, are criticised, and it is pointed out that Baudrimont's methods of analysis must have been untrustworthy.

The author intends continuing his experiments.

DISCUSSION.

Dr. PERCY FRANKLAND said that experiments made in the South Kensington Laboratory had given results in accordance with the equation—

$$8KClO_3 = 2O_2 + 5KClO_4 + 3KCl.$$

Care had been taken to prevent mechanical loss by placing a glass-wool plug above the chlorate; the decomposition had been effected at a known constant temperature; and the amount of residual chlorate had been determined.

Dr. ARMSTRONG remarked that the results now brought forward made it more than ever probable that, as he had previously suggested, the perchlorate simultaneously underwent decomposition even at a temperature below that at which it decomposes when heated alone: a considerable amount of heat is developed in the decomposition of potassium chlorate, and it was therefore to be expected that the amount of perchlorate formed would be less, and the amount decomposed greater, and hence that more oxygen would be obtained, when the decomposition was effected more rapidly, as the temperature would be locally higher.

Dr. TEED said that the results quoted by Dr. Percy Frankland confirmed his statement that the ratio of oxygen to chloride depends on the way in which the decomposition is effected; Dr. Frankland would find less oxygen produced at a lower temperature.

9. "*On the Sugars of some Cereals and of Germinate Grain.*" By C. O'SULLIVAN, F.R.S.

My attention has been called to a paper by Kjeldahl, of the Carlesberg Laboratory, Copenhagen, published in the *Transactions* of that Institution, in which this subject is treated. The methods employed are pretty much the same as those described by me, and the results obtained are practically confirmed by my work. Priority of publication of the chief points belongs, therefore, to Kjeldahl.

I regret very much that I should have missed this work of Kjeldahl, and I take the earliest opportunity of putting the matter right as far as I can. I may, however, say, in justice to myself, that there is sufficient novelty in the mode of treatment and in the details of my work to justify the publication of it even though I had seen Kjeldahl's paper.

10. "*Note on the Chemical Formula for Wool Keratine.*" By R. Lloyd Whiteley, Lecturer on Dyeing at University College, Nottingham.

Having occasion to calculate the approximate formula for the keratine found in wool fibre, according to "Bowman's Analyses" (p. 170, "Structure of the Wool Fibre," by F. H. Bowman), I was surprised to find what a different result I obtained from that given by Mills and Takamine (*Chem. Soc. Trans.*, 1883, xliii., 142), and quoted by Bowman. I therefore referred to Mills's data to ascertain wherein the difference lay, and found that in "Gmelin's Handbook," xviii., 351, from which the numbers had been obtained, there was an evident misprint, the values of the hydrogen and nitrogen in the percentage numbers being interchanged. This was confirmed on reference to two of the original papers, viz., Märcker and Schulze (*Annalen*, xl., 193—207), and Scherer (*Ann. Pharm.*, xl., 53).

Instead, therefore, of the formula $C_{42}H_{157}N_5SO_{15}$, as given by Mills (*loc. cit.*), the corrected results yield the formula $C_{41}H_{71}N_{12}SO_{14}$, obtained from the mean figures C 49·96, H 7·11, N 16·65, O 3·39, S 22·89 (by difference), in which probably the nitrogen is too low, and the oxygen correspondingly high.

Taking Dr. Bowman's later analyses we obtain the approximate formula $C_{43}H_{71}N_{13}SO_{13}$, from the mean figures C 50·27, H 7·05, N 18·37, S 2·90, O 20·40.

These figures are not quite free from objection, the carbon being probably rather h gh but considering the difficulty of completely purifiying the fibre from every trace of mechanically adhering mineral matter, it is probable that either of the two formulæ may be taken as closely resembling the true empirical one. This would apply to wool only, for though the analysis of other keratines, such as those of hair, horn, &c., closely agree in the amount of carbon and hydrogen, and fairly well in the amount of nitrogen, in the case of sulphur and oxygen they are proportionably much more divergent, so that it is impossible to represent them by any one formula.

11. "*Some Derivatives of Thiourea.*" By George McGowan, Ph.D., F.R.S.E.

In continuation of his examination of the derivatives of methylsulphonic acid (*J. Prakt. Chem.*, 1884, xxx., 280), the author has submitted thiourea to the action of trichloromethylsulphonic chloride. If the chloride,—

$$CCl_3 \cdot SO_2Cl,$$

be added to a cold aqueous solution of thiourea, no reaction takes place until after long standing, but on applying heat the chloride gradually dissolves, sulphur being deposited. On adding the chloride to a cold or nearly cold solution of thiourea in 80 or 90 per cent alcohol much heat is developed, and a mass of needle-like crystals separate out, the quantity being much increased by the subsequent addition of ether. The product is identical with the *dithiourea dichloride*, $(CSN_2H_4)_2Cl_2$, obtained by Claus by acting on thiourea with chlorine (*Annalen*, clxxix., 139). The same compound is obtained by the action of thiourea on mono- and di-chloromethylsulphonic chlorides and of phosphorus oxychloride, but the author failed to obtain it with acetyl chloride. When allowed to crystallise out from 90 per cent alcohol on a microscopic slide it forms highly characteristic, apparently monoclinic plates. It cannot be re-crystallised from water or alcohol, as the solutions invariably deposit sulphur. An aqueous solution strongly acidified with chlorhydric acid may, however, even be heated with impunity. It is perfectly stable at ordinary temperatures.

If dilute nitric acid be added to a moderately concentrated aqueous solution of the dichloride, a crystalline precipitate is produced in the form of jagged daggers or long sword-like plates, consisting of the nitrate—

$$(CSN_2H_4)_2(NO_3)_2.$$

These crystals were also observed to be formed in the mother-liquor from the preparation of thiourea nitrate, CSN_2H_4,HNO_3. The salt is almost insoluble in dilute nitric acid; more soluble, although sparingly, in water; practically insoluble in cold absolute alcohol and in ether. This is a comparatively stable compound, and in this respect differs from the thiourea nitrate described by Reynolds; but the author suggests that the instability of the latter may have been due to the presence of a small quantity of free nitric acid. A solution of potassium nitrate also produces a precipitate of the above nitrate in a cold aqueous solution of dithiourea dichloride.

If iodine chloride or trichloride be added to a cold alcolic solution of thiourea, dithiourea dichloride is formed, iodine separating. If potassium iodide and thiourea dichloride be suspended together in absolute alcohol they react to form urea, potassium chloride, and iodine. *Dithiourea diiodide*, $(CSN_2H_4)_2I_2$, can, however, be prepared by rubbing together in a mortar *pure* thiourea and iodine in the proportion of their molecular weights, sufficient alcohol being added to make a pasty mass; the reaction succeeds best when only small quantities are used. Once it is prepared the diiodide is quite stable, and can be preserved in a dry tube; it crystallises in long colourless prisms. It is at once decomposed by water, alcohol, and ether, iodine separating, but not by benzene. On heating the aqueous solution, or on addition of caustic alkali, sulphur separates, this separation of sulphur being characteristic of the dithiourea salts. Addition of dilute chlorhydric acid does not cau e the separation of iodine in the cold, but on heating the solution iodine is freely liberated, but no sulphur is precipitated: hence it is more easily decomposed under these conditions into iodine and thiourea than into sulphur, hydrogen iodide, thiourea and cyanamide (or derivatives thereof), these latter being the products which should result, according to Claus's observations on the dichloride.

The results are given of the complete analyses of the salts described in the paper.

At the meeting on February 4th, Dr. Klein, F.R.S., will deliver a lecture on "Methods of Bacteriological Research from a Biologist's point of view."

PHYSICAL SOCIETY.

January 23rd, 1886.

Prof. Guthrie, President, in the Chair.

The following communications were read:—

"*A Note on the Paper by Prof. W. Ramsay and Dr. S. Young 'On Some Thermodynamical Relations.'*" By Prof. W. E. Ayrton and Prof. John Perry.

The authors, after referring in the highest terms to the careful experimental work of Messrs. Ramsay and Young in their investigation upon "Some Thermodynamical Relations," the results of which were communicated to the Society at its last meeting, show that the four laws stated in their paper are in reality only one, since if any one of them is assumed the remaining three may be deduced from it. Hence it is sufficient to examine only one, and of the four the third is in the form that can be most

readily tested. This law, the statement of which is that for all substances at any given pressure the product $t\frac{dp}{dt}$ is constant, p being the pressure and t the absolute temperature of saturated vapour at that pressure, is represented mathematically thus:—

$$t\frac{dp}{dt}=\phi(p) \quad . \quad . \quad (1),$$

$\phi(p)$ being a function of the pressure, independent of the substance. Writing this equation—

$$\frac{dp}{\phi(p)}=\frac{dt}{t}$$

and integrating, we get—

$$t=a\psi(p) \quad . \quad . \quad (2).$$

$\psi(p)$ being also a function of the pressure only, and a a constant depending only upon the substance employed. It is in this form that the authors have examined the third law: if true, it follows at once (from 2) that the ratio of the temperatures of two saturated vapours to one another at any pressure is the same as the ratio at any other pressure. It is seen, however, either by reference to Regnault's numbers, or Rankine's formula,—

$$\log. p=\alpha-\frac{\beta}{t}-\frac{\gamma}{t^2} \quad . \quad . \quad .$$

an expression based upon his molecular theory, and which, as remarked by one of the authors at the last meeting, agrees with Regnault's results with remarkable closeness, that this ratio is far from constant. The authors are therefore compelled to conclude that the expressions given by Prof. Ramsay and Dr. Young must not be regarded as absolute laws.

"*A Note on the Paper by Prof. J. W. Clarke, 'On the Determination of the Heat-capacity of a Thermometer.'*" By A. W. Clayden.

The author has applied a correction to an expression given by the late Prof. J. W. Clarke for measuring the heat-capacity of a thermometer, in a paper communicated to the Society at a previous meeting (April 25th, 1885). Prof. Clarke's expression was affected by the mercury not entirely filling the bulb and stem of the thermometer. The corrected expression obtained by the author is—

$$V_1=\frac{V(S-S_2)}{S_1-\frac{S_2(1+\beta t)}{1+\alpha t}}$$

S, S_1, and S_2 being the mean densities of the instrument, mercury and glass respectively; β and α the coefficients of voluminal expansion of mercury and glass; V and V_1 the volumes of the instrument and of the mercury.

"*Note on some Organic Substances of High Refractive Power.*" By H. C. Madan.

In the course of some correspondence respecting M. Bertrand's polarising prisms, the author was informed that the cement used was naphthyl-phenyl-ketone dibromide. He has consequently prepared specimens of the ketone, and subjected them to optical examination. The ketone is a thick yellow oil, boiling at a temperature near the boiling-point of mercury; it appears to be a very stable, neutral, and harmless substance, like Canada balsam, but unfortunately it does not appear to be capable of hardening, and hence is not by itself adapted for a cement. Its refractive index for the D line is 1·666, higher than that of carbonic sulphide, while its dispersive power is approximately the same as that of that substance. The author has made the bromide of the ketone referred to above, but it seems liable to decompose, with formation of hydrobromic acid, which acts upon the spar. Mr. Madan also exhibited a specimen of metacinnamene, a highly refracting glass-like solid, obtained by the action of light or heat upon cinnamene. This substance possesses a refractive index of 1·593 for the D line, and would make a valuable cement if it showed a firm adhesiveness for glass.

The President exhibited and described an instrument he had made in the course of an acoustical investigation upon which he had been engaged. It is a musical instrument, similar in principle to the harmonicon. In the case of the harmonicon the rectangular plate is usually supported by strings passing through the nodes, but the author wished to make an instrument that could be "bowed." The "nodes" are not absolute positions of rest, the particles at them describing curves having cusps pointing outwards. The plan adopted was to solder two springs to the plate, which was of brass, the points of attachment being slightly outside the nodes, and the springs being such as to give the same fundamental note as the plate. The other ends of the springs were attached to the mouth of a resonator whose fundamental note was also that of the plate. The plate when struck or bowed gave a tone very like that of a tuning-fork; and in a discussion that followed Prof. S. P. Thompson suggested the possible use of these instruments as a substitute for a series of forks, the cost of a complete set of which often places them beyond the reach of the student.

Prof. M'Leod suggested that the springs should be tuned to the octave of the plate instead of to its fundamental, and that they should have a slightly different form.

NOTICES OF BOOKS.

The Retrospect of Medicine: being a Half-yearly Journal containing a Retrospective View of every Discovery and Practical Improvement in the Medical Sciences. Edited by James Braithwaite, M.D. Vol. XCII., July to December, 1885. London: Simpkin, Marshall, and Co.

Among the more noteworthy papers in this summary of medical progress is one by Prof. Kônig, of Göttingen, on the disinfection of rooms. He fumigates with corrosive sublimate, and afterwards with sulphur. The results have been found satisfactory in practice. There is the additional advantage that bugs and flies, which may now be recognised as *colporteurs* of infectious disease, are exterminated. The subsequent treatment with sulphur prevents any mischief resulting from mercurial vapours. From 50 to 60 grms. of mercuric chloride is a sufficient dose.

Surgeon-Major Pringle, M.D., of the Bengal Army, communicates an important paper on Asiatic cholera. He considers sanitary cordons, and the disinfection of travellers and their luggage, as useless in practice. He would not, however, allow passengers and luggage to land from a ship which has true cases of cholera on board. The period of incubation of the infection he estimates as, on the outside, seventy-two hours. He holds that cholera is neither contagious nor infectious in the sense in which these terms are applied to smallpox and eruptive fevers generally.

Actinomycosis is an instance, more curious than pleasant, of a disease due to a fungus. The little masses of mycelium may be recognised by the naked eye as sulphur-coloured bodies about the size of a hemp-seed.

Dr. G. Oliver, in a paper on the "Clinical study of the Liver viewed through the Urine," points out that the detection of bile acids by the direct application of Pettenkofer's test to urine is practically impossible, even when present in considerable amount. He runs albuminous urine, acidified with acetic acid, over a jaundiced urine. Along the plane of contact of the two urines a sharply-defined white band of precipitated albumen will appear.

Means of Destroying Mice.—Dr. Crampe.—Wheat poisoned with strychnine is the most efficient agent. The great objection to poisons is that if the mice die in the open field they may occasion the death of owls and other mice-destroyers.

CORRESPONDENCE.

THE INSTITUTE OF CHEMISTRY.

To the Editor of the Chemical News.

Sir,—Will you allow me to give a report of a meeting of members which took place at the rooms of the Chemical Club of Manchester, on Wednesday last, the 20th inst., with a view of further discussing the Resolutions which were adopted at the previous meeting, and of taking such steps as they might consider advisable for giving effect in the Council to the feeling of the majority of the members in these matters.

The following members were added to the Committee *pro tem.*:—

R. F. Carpenter	W. Douglas Herman
George E. Davis	Charles O'Neill.
Thomas Fairley	

The following Resolutions were carried unanimously. For the sake of reference I have numbered them consecutively with those published in the Chemical News (vol. liii., p. 34):—

6. That Resolution No. 3 of last meeting be extended to read as follows:—

   That this meeting considers it desirable that the existing regulation of the Council, to the effect that a candidate for the Associateship must have studied three years in one of a limited number of specified colleges, should be extended, so as to allow such candidate to present himself for examination provided he has studied and practised for at least three years in the laboratory of a Fellow of the Institute in actual practice. *Provided that during that term or at some time previous to his presenting himself for examination he has attended thorough courses of instruction in Theoretical Chemistry, Physics, and Mathematics, and that the examinations for the Associateship should include the subjects of Physics, Mathematics, and the general subjects of English education (as well as Practical Chemistry), unless the candidate presents certificates of having passed sufficiently advanced examinations in those subjects.*

7. That this meeting feels that there ought to be a greater number of provincial members in the Council, to represent the provincial members, than is at present the case.

8. That it is desirable that provision should be made for General Meetings of the Institute in provincial towns, and that the Annual Meetings be held alternately in London and in one of the towns in the provinces.

9. That the Resolutions passed at both the meetings of Fellows at Manchester be presented to the President and Council of the Institute.

I may say that up to the present I have received replies from sixty-four members who practically agree with the Resolutions passed at the first meeting. I have also received some letters from members, who, as far as I could judge, practically agree with the Resolutions, but who expressed dissent in such a way that I could not add their names to the above list.

Sixteen members refused to give any opinion, whilst only six members expressed decided objection to any or all of the Resolutions.

I have received replies from about 100 members out of 360 living in London or in the country, and we shall be glad if any of those members who have not yet replied will be kind enough to do so, that the Committee may have before them a still larger representation of the views of the members on the important questions mentioned in the Resolutions.

The object of the Manchester Committee is to aid the Council in making the Institute more efficient and valuable to its members, and with this end in view they ask the opinions of all the Members and Associates on the questions given in the above Resolutions or in those already published.

I understand that the Council have themselves suggested the reduction of the annual subscription. With reference to Resolution No. 1 the Manchester Committee feel that the members should try to get all chemists of standing who are not at present members to join the Institute: there are, of course, some who for various reasons will not join, and these will no doubt prove a source of weakness to the Institute; but we think if the large majority of members will do their duty to the Institute, and consequently to themselves, there will be comparatively few who will prefer to remain outside. We think, however, that those chemists of standing who refused to aid, either with moral or pecuniary support, the founders of the Institute, should only be permitted now to join by paying a considerable entrance-fee, as it cannot be considered just that they should reap the benefits which have been bought by the money subscribed by those who have gone on adding to the funds during the last 8½ years, the policy hitherto having been mainly one of waiting and collecting money for future operations.

The questions involved in Resolution 3 are those which I understand meet with the greatest opposition in the present Council. Some of those who oppose Resolution No. 3 do so on the ground that examination does not test the ability or knowledge of a candidate. To this we reply, you cannot accurately estimate the value of men by examination, but stringent examinations by different examiners would show that the candidate is up to some fixed standard so far as knowledge is concerned. The next objection is that it will foster "cramming": the objectors propose that the compulsory attendance at certain specified schools or colleges, and the passing of an examination which presumably might be passed by a moderate amount of "cramming," is the better method. There would by the latter be many candidates who would learn next to nothing at the specified schools or colleges, and would ultimately undergo the process of cramming to pass the examination. Whilst necessarily these would grow up chemists outside the Institute, who would be better men in every way than the average Fellow of it, and who would soon prove that it was no discredit to be an outsider. Again, it would prove a hardship to many men endowed with the qualities of brain which make the best chemists, who are too poor, or for other reasons cannot leave the town in which they were born, to study in one of the specified colleges, but who might make rapid progress in his studies under one of the Fellows of the Institute. We do not undervalue the great advantages of a regular collegiate training, which everyone would doubtless obtain who could, but we think the Council should arrange for the entrance of Associates on a broader basis than that which they have laid down, and that the degree of the Institute be of the same nature as those of the London University, no special questions being asked of the candidate from where he obtained his knowledge, provided he possesses it.

In conclusion I may mention, in reference to resolution 7, that there are at present about 167 London, 194 Provincial, and 30 Foreign Fellows, and 43 London, 49 Provincial, and 8 Foreign Associates in the Institute; and there are 26 London Members of Council to represent 210 London Fellows and Associates, and 10 Provincial Members of Council to represent 243 Provincial Fellows and Associates. By London Members I include those who reside at Woolwich, or within a similar distance from the centre of London; and whilst no objection could be taken to any of the eminent chemists who at present form the Council, we think a better representation of the views of the majority would be given by a more equal distribu-

tion of seats on the Council in London and in the provinces.—I am, &c,

William Thomson,
Hon Sec. pro tem.

Royal Institution Laboratory,
Manchester, January, 26, 1886.

THE INSTITUTE OF CHEMISTRY.

To the Editor of the Chemical News.

Sir,—In your last issue Prof. Ramsay considers that a reduction of life fee to Fellows of the old Institute would give original life-members a claim for repayment. At first sight his objection to the proposed rule seems tenable; but it must be remembered that old "lifers" have had no annual contribution to pay, and that many members, like myself, have since their election paid, as annual subscriptions, a sum of money equal to the amount of a life subscription, and it would be therefore no hardship to old "lifers" if those annual fees were to be taken into account.

I think myself that it would be no more than fair that Fellows of the old Institute should be allowed to become life-members of the new Institute, with a reduction of fee depending upon the amount of their annual subscriptions already paid.—I am, &c.,

P.

CHEMICAL NOTICES FROM FOREIGN SOURCES.

Note.—All degrees of temperature are Centigrade unless otherwise expressed.

Comptes Rendus Hebdomadaires des Séances, de l' Académie des Sciences. Vol. cii., No. 1, January 4, 1886.

Researches on Antimony Sulphide.—M. Berthelot.—The author investigates here the formation-heat of antimony sulphide and that of antimony chlorosulphide. He also describes sulphantimony hydrosulphate, chlorantimony hydrochlorate, and the sulphantimonites of the sulphites.

The "Emetics" of Tellurium.—Daniel Klein.—Berzelius found that no definite isolable compound is formed on dissolving tellurous hydrate in a solution of potassium bitartrate. The author has succeeded in preparing some tartro-tellurous emetics, by setting out from the tellurites of the alkaline metals and treating them with a certain proportion of tartaric acid. In an analogous manner he has formed the double citrate of potassium and tellurous acid. He has thus formed and examined the tartro-tellurites of potassium and of sodium, the tartro-tellurite of lithium, and the citro-tellurite of potassium.

Transformation of the Oil of Turpentine into Active Terpilene.—MM. Bouchardat and J. Lafont.—The oil of turpentine has been transformed into a carbide of properties closely bordering upon those of the oil of citron,—a lævo-rotatory terpilene the deflecting power of which for yellow light is close upon $-65°$. Citrene is dextro-rotatory, $=+104{\cdot}9°$. This carbide, $C_{20}H_{16}$, occupies in the series of bivalent terpilenic carbides a place parallel to that occupied by the active camphenes in the isomeric series of monovalent camphenic carbides.

Use of Metallic Oxides for detecting Coal-Tar Colours in Wines.—P. Cazeneuve.—This paper will be inserted in full.

Poisonous Action of Alkaline Salts.—Charles Richet.—The author finds that among substances chemically analogous, such as the alkaline salts, the fatal dose is approximately equal if we consider not the absolute weight but the molecular weight of the substances. In absolute weights the metals are the less poisonous as their atomic weight is higher, which is precisely the inverse of Rabuteau's law. For equal molecules the metals whose atomic weight is the highest are also rather more poisonous. The chlorides are in absolute weight more poisonous than the bromides, and the bromides more than the iodides. But for equal molecular weights the inverse order is observed, the chlorides being a little less poisonous than the bromides and the bromides less than the iodides.

No. 2, Jan. 11, 1886.

Multiple Conditions of Antimony Sulphide.—M. Berthelot.—The transformation of the black sulphide into the orange sulphide gives thermic effects which are very feeble or altogether null. Such sulphides, having a low formation-heat, retain up to a certain point the lustre and the various characters of the bodies whence they are derived. We may remark the great difference which exists between the formation-heat of antimony sulphide and those of antimony chloride and oxide.

Reciprocal Actions and the Equilibria between Hydrochloric Acid, Hydrogen Sulphide, and the Salts of Antimony.—M. Berthelot.—Inverse actions are produced in cases where the sign of the heat evolved by the reaction of two bodies, such as antimony sulphide and hydrogen chloride, is changed by the combination of one of them with a third body, such as the water which forms hydrates, or even with one of the products of the reaction. The chemical action is not reversed abruptly, but according to a gradation of intermediate compounds, such as hydrates, hydrosulphates, hydrochlorates, oxychlorides, chlorosulphides, &c., compounds whose special formation-heat intervenes in the phenomena and tends to fill up the thermic interval between the principal reactions, These secondary compounds, for the most part, exist merely in a state of partial dissociation, that is to say, of tension of their compounds. These compounds determine and regulate the chemical equilibria between the antagonistic bodies.

Variations of Absorption-Spectra and of Emission-Spectra by the Phosphorescence of one and the same Substance.—H. Becquerel.—This memoir will be inserted at some length.

Hydrates of Hypophosphoric Acid.—A. Joly.—The author describes the tetrahydrate. He considers that hypophosphoric acid is as clearly defined by its crystalline hydrates as the phosphoric and phosphorous acids, and it equals them in stability.

Solubility of Copper Sulphate in presence of Ammonium Sulphate.—R. Engel.—Increasing quantities of ammonium sulphate precipitate copper sulphate as a double salt. If we leave a double sulphate at 0° in a saturated solution of ammonium sulphate for some days the liquid remains colourless or takes a blue tint scarcely visible.

On Certain Compounds of Acetamide with Metallic Chlorides.—G. André.—An account of the combinations of acetamide with cupric chloride, cadmium chloride, mercuric chloride, and nickel and cobalt chlorides.

On Iodaldehyd.—P. Chantard.—Iodaldehyd is a limpid, oily liquid, volatile, not inflammable, colourless, but blackening rapidly in the light. It is decomposed at 80°, and cannot be distilled unchanged, even at the pressure of 0·22 metre. It does not solidify at 20°. Its vapours attack the eyes and the respiratory organs so severely that it can be manipulated only in the open air. Its density is 2·14. It dissolves in all proportions in alcohol, ether, benzol, chloroform, and carbon disulphide. With ammonia it yields, at the ordinary temperature, the different terms of the series of oxaldines, according to the proportions.

Bulletin de la Société Chimique de Paris.
Vol. xliv., No. 12, Dec. 20, 1885.

Memoir on the Alkaline Hydrates.—E. J. Maumené.—The author maintains that the potassium, sodium, barium, and strontium hydroxides have not one single formula; they have never, and cannot have, the classical formula MO.HO (old notation). All the other hydrates of oxides are in the same case; the rule applies to all hydrates without exception, those of acids, salts, and so-called organic compounds. All bodies capable of hydratation present a series of calculable hydrates. Thus we have for potassa—

$(KO)_9\ (HO)_{47}$ up to 400°.
$(KO)_9\ (HO)_{47/3}$ from 400° up to 650° or 700°.
$(KO)_9\ (HO)_{47/7}$ from 650° or 700° up to about 1000°.

Experiments on the Fatty Bodies.—C. Dubois and L. Padé.—The authors give a table of the solubility of fats in different solvents at 12°. They have then examined the solubility of mixtures of fatty acids, and find that the solubility of the fatty acids of butter is reduced by 1·24 per cent by an addition of 5 per cent of the fat of veal.

Combustion-Heat of Certain Amines.—A. Müller.—The author finds that the affinity of R for nitrogen increases with the complication of the radicle. According to J. Thomson's formula, on the contrary, the affinity of every monatomic alcohol radicle for hydrogen is represented by the constant number 14·57 cal.

On Acid Magenta in Wines.—P. Cazeneuve.—Already noticed.

On a New Method of taking the Melting-point and Solidification-point especially of Neutral Fatty Bodies and of their Acids, but applicable also for the same purpose to all Substances which behave in an Analogous Manner with Heat within certain Limits of Temperature.—M. Loriton.—The author gives a description of a special apparatus for observing the phenomena of solidification and fusion under the microscope.

A Contribution to the Study of the Alkaloids; on the Detection and Determination of the Bases of the Pyridic and the Quinoleic Series.—M. Oechsner de Coninck.—When it is required to search for and determine this series of bases, it is necessary to prepare the chloro-platinate, and endeavour to modify it with lukewarm water. The quinoleic hydrides are also powerful reducing agents.

Zeitschrift für Analytische Chemie.
Vol. xxv., Part 1, 1886.

A New Method for the Determination of the Specific Gravity of Gases, and for their Analyses.—Fried. Lux.—This paper requires the seven accompanying figures.

Determination of the Melting-points of Fats.—C. Reinhardt.—The author's procedure cannot be explained without the four accompanying illustrations. He mentions that the figures given for beef-tallow range from 37° to 52·5°, and those for mutton-tallow from 38° to 52°.

Chemical Examination of Beers in General, and a New Direct Method of determining Alcohol in Fermented Liquors.—E. Bohlig.—This paper cannot be usefully reproduced without the illustration.

Analysis of so-called Swedish Beer.—J. Groinigg This liquid contains very variable quantities of alcohol, extract, sugar, gum, with small quantities of glycerin, and in some cases traces of succinic acid.

The Gravimetric Determination of Zinc, with particular reference to so-called Zinc-Ash.—Dr. L. Marquardt.—This paper will be inserted in full.

New Coloured Reactions of Certain Alkaloids.—W. Lenz.—If a little potassium hydroxide, purified with alcohol, is fused upon the lid of a porcelain crucible with a little water, mixed with a trace of the substance to be examined (preferably dissolved in alcohol), and the whole is then very cautiously and gradually heated over a steady flame, finally to redness; the mass in most cases takes a yellow colour, passing into red or brown, and ultimately becoming carbonised. In the following bases the colours were not characteristic:—Aconitine, anemonine, aspidospermine, atropine, baptisine, bebeerine, berberine, bryonine, brucine, caffeine, cannabine, cantharidine, chelidonine, chlorogenine, codeine, colchicine, colocynthine, colocynthidine, coniine, cotoine, cryptopine, curarine, cyclamine, daturine, delphinine, digitaline, ditaine, duboisine, elaterine, emetine, erythrophlæine, gelsemine, gentisine, helleboreine, hydrocoteine, homatropine, hyoscyamine, hydrastine. hyoscine, kosine, leptandrine, lobeliine, lycoctonine, meconine, morphine, napelline, narceine, narcotine, papaverine, papazotine, pelletierine, peucedanine, physostigmine, pilocarpine, piperine, podophyllotoxine, sabbatine, scillitoxine, scoparine, solanine, sparteine, strychnine, and veratrine. On the contrary, quinine and quinidine give an intense grass-green, cinchonine and cinchonidine a bluish green, and cocaine a greenish yellow, which, on more prolonged heating, passes into a bluish colour, and then into a dirty rose. Apomorphine, sabadilline, and thebaine display at first a faint green colour, which afterwards passes into yellowish brown, and is not to be confounded with the characteristic colours of the quinine group. A sample of chinoline tartrate, bought several years ago, and a pure chinoline from the same source, gave the green colour noticed under quinine; but on testing a recent sample of "purest" chinoline this reaction could not be obtained. Ptomaines obtained from five different dead men, and from a piece of sausage which had occasioned the death of two persons, gave no coloured reaction on fusion with potassa. The author, being prevented by his present engagements from carrying out this investigation, hopes that some other chemist will ascertain the result of adding oxidising and reducing agents to the melted potassa.

A New Absorption-Apparatus for the Determination of Carbonic Acid.—F. Strohmer.—The apparatus cannot be intelligibly described without the figure.

Use of Schœne's Apparatus for Washing Clays and Soils.—Carl Holthof.—The author gets rid of the defects of the apparatus by filling the deepest, curved part so far with mercury that the water in both limbs only just communicates over the surface of the mercury.

Reflux-Condenser for Analytical Extraction-Apparatus.—F. Allihn.—This paper requires its illustration.

Preparation of a Stable Starch Potassium-Iodide Solution.—C. Reinhardt.—The determination of nitrous acid in waters has generally been effected with starch-zinc iodide in preference to the ordinary unstable starch-potassium iodide solution. Alex. Müller has indicated a process for obtaining a permanent solution of starch, treating the starch with potash lye, and thus produces a reagent which becomes clear and keeps for years. The author, taking this as a starting-point, has made some direct experiments on the subject, and finds Müller's statements confirmed. He used this alkaline solution of starch in the titration of iron with stannous chloride, and he has also attempted with success the preparation of a permanent solution of starch-potassium iodide. He puts into an Erlenmeyer flask 5 grms. of starch ground to a fine powder, adds about 50 c.c. of water, shakes well up, washes the starch which clings to the sides of the flask down by means of a washing-bottle, and adds with a pipette 25 c.c. of potash-lye (1 part potassium hydroxide purified with alcohol to 2 parts of water). He shakes well, when there is formed a uniform gelatinous mass. He adds 500 c.c. of water and 2 grms. potassium iodide, and heats flask on an asbestos plate to boiling, shaking frequently, when the solution becomes clear. He lets cool, pours the liquid into a graduated cylinder holding 1000 c.c., fills up to the mark with water, and filters.

This solution does not require to be preserved in the dark.

Simple Arrangement for Azotometers.—Alfonso Rosa.—In determining total nitrogen by the method of Dumas, nitric acid by that of Schultze-Tiemann, and in many gasometric operations, the fingers come in contact with strong alkaline solutions. To avoid this evil the author fills the eudiometer, held perpendicularly with the lye, and lays upon the meniscus of the liquid rising above the opening a paper filter of a rather larger diameter than that of the eudiometer. This filter clings firmly to the aperture and permits the eudiometer to be inverted and brought to the place of its destination without admitting air or wetting the hands with the lye.

Working up Uranium Residues.—Prof. U. Kreusler.—The author reminds us that the method of separating the phosphoric acid by means of tin, recently proposed by Savory, had been published by himself twelve years ago.

Bacteriological Examination of the chief Sources of the Wiesbaden Water-Supply, as well as of a number of Mineral Springs at Schlangenbad, Schwalbach, Soden, and Weilbach.—Robert, Baron von Malapert-Neufville.—The bulk of this very important paper will be inserted as early as possible.

"Microscopic Reactions."—K. Haushofer.—In this book the author gives instructions for the detection of various elements and compounds with the microscope.

A Method of Gas-Analysis.—J. Geppert.—The author's process has been discussed in this journal, vol. xxii., p. 405.

An Effect of Capillarity.—J. U. Lloyd.—From the Chemical News.

The Absolute Unit of Light.—J. Violle.—A notice of the author's proposal to take as standard unit the quantity of light emitted by one square centimetre of platinum at its solidification point.

Prisms for the Polarisation of Light.—K. Feussner.—This treatise is merely mentioned.

Certain Sources of Error in the Balance.—R. Hennig.—A current of air may be produced if an evaporating fluid in a beaker is placed upon one scale. The error may amonnt to 0·4 m.g. A source of error, less common, but sometimes more serious, is electric action produced by friction of the balance-case and consequent attraction of one scale-pan. T. E. Thorpe (*Journal Chem. Soc.*) calls attention to small daily fluctuations of the zero-point.

Preparation of Volumetric Solutions of Exact Strength.—E. Pflüger.—The author uses gauged flasks holding respectively 1, 2, or 4 litres with a small flask fused to the neck above the mark.

Determination of the Specific Gravity of Liquids at Elevated Temperatures.—R. Schiff.—This paper requires the accompanying diagram.

A New Form of Combustion-Tubes.—T. B. T. Bruce Warren.—From the Chemical News.

Apparatus for Determining Carbonic Acid in Absorption Gases.—D. Sidersky.—Unintelligible without the figure.

Small Gas-Furnace for the Production of High Temperatures.—H. Rössler.—(*Chemiker Zeitung.*)

VOL. LIII. No. 1367

ON AN ELECTRIC SPECTRUM PECULIAR TO THE RARE EARTHS OF THE TERBIUM GROUP.

By M. LECOQ DE BOISBAUDRAN.

Some years ago I observed and sketched a peculiar spectrum, which appeared with various terbic oxides when the induction-spark struck on the surface of their hydrochloric solutions. These oxides (complex mixtures confounded together under the name of terbia) contain very variable proportions of yttria, holmia, ytterbia, samaria, erbia, and of the yellow earth. The spectra of their hydrochloric solutions comprise at least the rays of yttria and ytterbia, this latter body being always very abundant in such mixtures. It was nevertheless possible to show that the special spectrum in question could not be ascribed to any of the known earthy metals except holmium and terbium, the latter being supposed to be characterised by the yellow colour of its oxide.

The numerous fractionations which I have carried out since that time have placed in my hands some series of products still containing several elements, though practically freed from the bodies formerly known which yield spectra with their hydrochloric solutions exposed to the ordinary induction-spark. The special spectrum is thus seen very well in the absence of the rays of Yt, La, Tu, Ya, Sc, Yb, and by means of solutions which show by absorption very little or none of Di, Sm, Er, Tu. In the conditions of the experiment cerium, thorium, and zirconium emit no rays, so that our spectrum can be attributed only to holmium, terbium, to a new body, or, lastly, to the earths which produce the fluorescences $Z\alpha$ and $Z\beta$.

The yellow tint of its oxide when calcined in the air has always been considered as peculiar to and characteristic of terbium. It seems to me, therefore, very natural to retain the name terbia for the most coloured earth of the group. If this is admitted the special spectrum cannot be attributed to terbium, since it appears slightly more brilliant with the oxides which are slightly coloured than with those, much darker, which are derived from the fractionation of one and the same yellow earth by means of potassium sulphate. The least soluble double sulphates yield the most coloured earth.

Admitting, in the absence of proof to the contrary, the non identity of $Z\alpha$ and $Z\beta$, the spectrum in question seems not belonging to $Z\beta$, the fluorescence of which is the finest with the most deeply coloured earths.

The special electric spectrum follows, in its degrees of intensity, a movement in the same direction as the absorption-spectrum of holmium, if we consider the successive stages of each of my fractionations by potassium sulphate. The variations of intensity do not, indeed, appear quite proportional; but on comparing the substances obtained by fractionation (always by means of potassium sulphate), we observe so well-marked deviations between the intensities of the absorption-spectrum of holmium and of the electric spectrum, that it seems to me difficult to attribute this latter to holmium.

The uncertainty which still prevails concerning the manner of producing the fluorescences Sm, $Z\alpha$, and $Z\beta$, —an uncertainty which may throw a doubt on the conclusions drawn from the comparison of the intensities of these fluorescences,—does not exist in the same degree in case of the electric spectrum. Therefore my impression is that holmium is not the cause of our spark spectrum.

As for the fluorescence $Z\alpha$ it is remarkable to see it follow the variations of the special electric spectrum, not merely within one and the same function, but also when we compare products of different origins. The relative intensities of the electric spectrum and of the fluorescence $Z\alpha$ seem to vary a little, but, considering our still very incomplete knowledge of the fluorescences, I do not feel warranted in concluding that these variations indicate clearly the existence of two distinct elements.

Nevertheless, to avoid future confusions of nomenclature, I designate provisionally the body producing the electric spectrum as $Z\gamma$. It is composed of several bands and rays which always preserve substantially their relative lustres, and which therefore must be considered for the present as belonging to a single element.

The following are the approximate positions of the principal rays and bands of $Z\gamma$:—

	Positions on my Micrometer.	λ	Observations.
	101⅓	583·5	Nebulous ray; fairly well marked. It stands out on a small very nebulous band, carrying other less marked maxima.
	102⅓ (about)	,,	Indistinct commencement of band.
	104⅓	575·0	Nebulous ray; broad and well marked; much stronger than 101⅓.
α	105·⅞	570·0	Very nebulous ray; moderately broad, very easily visible, but much weaker than 104⅓; terminates the band.
	106·⅛	,,	Very nebulous extremity of the band.
	121⅓ (about)	,,	Nebulous commencement of a small band, which increases in its entire from left to right, This band bears several fine, but slightly nebulous, rays (visible with a narrow slit), which increase in intensity from the left side to the ray 122·15, the most brilliant of all. From this ray to the extremity of the band the light is very faint.
	121·95 (about the half apparent)	526·9	Apparent middle of the entire band. This is the position measured with a rather broad slit.
	122·15	525·9	Strongest ray. Forms the right margin of the principal part of the band. Very well marked.
	122⅓	,,	Nebulous extremity of the band. This band is slightly fainter than α, 102⅓ to 106·⅛.

—*Comptes Rendus* (vol. cii., p. 153).

ON THE USE OF METALLIC OXIDES FOR DETECTING COAL-TAR COLOURS IN WINES.

By P. CAZENEUVE.

THE author brings before the Academy a certain and very precise general method for detecting, in wines, magenta, azo-colours, and others, so much employed at present. This method is based upon the use of metallic oxides, properly so called. He has employed in particular yellow mercury oxide, moist lead hydroxide, and gelatinous ferric hydroxide.

The colouring-matter of wine—a kind of tannin—is a feeble acid, forming insoluble lakes with a great number of metallic salts, including those of lead, mercury, and iron. An excess of these salts either re-dissolves the metallic lake or acts upon foreign artificial colouring-matters. The author thought that the direct intervention of the oxides of these metals, which are feeble and insoluble bases, would fix the normal colouring-matter of wine, without destroying most of the coal-tar colours, and without forming combinations with them. Experiment has confirmed these views.

A. *Yellow Mercury Oxide.*—This oxide, both in the cold and in heat, retains the normal colouring-matter of wine, and, in addition, cochineal and the vegetable colours used for wines, and this in a complete manner: 0·20 grm. of the oxide suffices to decolourise 10 c.c. of wine.

On the contrary, it lets pass on filtration, both in the cold and in heat, the sulpho-conjugated derivative of magenta even in traces; further, especially in heat, the following colouring-matters:—Bordeaux red B, soluble red (the sodium salt of the sulpho-conjugated derivative of roccelline), purple-red, croceine 3 B, scarlet (Biebrich red), ponceau R, ponceau B, orangé R, orangé RRR, orangé II, orangé RR, tropæoline M, tropæoline II, yellow I, fast yellow, binotro-naphthol yellow, yellow NS. These colours pass away entirely, even if present in small quantity.

The mercury oxide seems to keep back a part of the following colours: — Orangé I, safranine, chrysoidine, chrysoine, methyl-eosine, yellow II, red NN, red I, ponceau RR. It retains entirely erythrosine, eosine J, methylene blue, Coupier's blue, diphenylamine blue.

All these experiments, like the following, have been made with small proportions of the colouring-matter representing the fourth, or even less, of the total colouration of the wine. They have always been performed along with wine, as the conditions of the medium change the reaction. We cite the case of erythrosine, which passes away in an aqueous solution, but is retained in presence of wine. The heat used was carried to the boiling-point.

B. *Lead Hydroxide.*—This hydrate, containing 50 per cent of water, has been applied in the proportion of 2 grms. to 10 c.c. of wine. In the cold, after agitation for a minute or two, it retains the normal colouring-matter of wine, which is also effected by bringing the whole to a boil. All vegetable colours and cochineal are also retained.

Contrary to mercury oxide, this oxide lets the rosanilines pass very readily. (The author has not previously mentioned that they are kept back by mercury oxide.) Rosaniline hydrochlorate, sulphate, acetate, oxalate, and arseniate have been tried, the filtrate being acidulated so as completely to regenerate the salt of rosaniline. It lets pass orangé I (with a rose tint), safranine, orangé R, orangé RRR (with a rose tint), tropæoline M, tropæoline II, chrysoidine, chrysoine, orangé II, methyl-eosine, fast yellow, binitro-naphthol yellow, yellow NS, yellow I, ponceau B. It retains partially eosine J, yellow II, red I, ponceau RR.

Like mercury oxide it retains entirely methylene blue, Coupier's blue, diphenylamine blue, and erythrosine; but unlike mercury oxide—and the fact is remarkable—it retains the sulpho-conjugated derivative of magenta, Bordeaux red B, purple-red, and the soluble red of roccelline.

C. *Gelatinous Ferric Hydroxide.*—This oxide has been used containing 90 per cent of water, 10 grms. to 10 c.c. of wine. It is mixed in the cold, and the mixture heated to a boil. Pure wine is completely decolourised; cochineal and the vegetable dyes are retained. The following colours pass:—Erythrosine, which is retained by mercury and lead oxides; then the sulpho-conjugated derivative of magenta, Bordeaux red B, purple, soluble red, and fast yellow. All the rose anilines except the sulpho-conjugated compound (acid magenta or magenta S) are retained. The less important colours have not yet been examined.

Stannous hydrate and zinc hydrate give encouraging results. Some colours pass, whilst others are retained totally or partially, with the formation of lakes of different and often of characteristic colours.

Thus there is possible a general method for the distinction of these colours, or for their separation. The comparison with a standard solution, dyeing silk and wool, the reaction of strong sulphuric acid, spectral reaction (Girard and Pabst), and the solubility in amylic alcohol will permit the recognition of their nature.

The treatment of wine with magnesia and hot amylic alcohol isolates and distinguishes many of the artificial blues which are kept back by the oxides of lead, iron, and mercury.

The author hopes to extend this method so as to distinguish the natural colours. Thus stannous hydrate easily retains the normal colour of wine, but lets cochineal and orchil pass. From wine it is but a step to recognise artificial colours in syrups, liqueurs, &c. — *Comptes Rendus*, vol. cii., p. 52.

AN ELECTRICAL FURNACE FOR REDUCING REFRACTORY ORES.*

By T. STERRY HUNT.

The application of electricity in the extraction of metals has hitherto been chiefly confined to the electrolysis of dissolved or fused compounds of these by various methods. The power of electric currents to generate intense heat in their passage through a resisting medium has, however, long been known, and the late W. Siemens thereby succeeded in fusing considerable quantities of steel. But it was reserved to Messrs. Eugene H. and Alfred H. Cowles, of Cleveland, Ohio, to take a new step in the metallurgic art by making the heat thus produced a means of reducing, in the presence of carbon, the oxides not only of the alkaline metals, but of calcium, magnesium, manganese, aluminium, silicon, and boron, with an ease that permits the production of these elements and their alloys with copper and other metals on a commercial scale.

In the apparatus devised and now employed by the Messrs. Cowles, a column of fragments of well-calcined charcoal, so prepared and arranged as to present the requisite electrical resistance, is imbedded horizontally in finely pulverised charcoal, and covered by a layer of the same material coarsely broken, the whole being arranged in a box of fire-brick, covered with perforated tiles and opened at the ends to admit two carbon electrodes an inch and a half in diameter. Through these the current from a dynamo-electric machine of 30 horse-power is now made to traverse the central core of carbon fragments, whereby such a temperature is at once produced therein that platin-iridium may be instantly melted, and the most refractory oxides already named are not only fused and volatilised, but reduced to their elemental state, with formation of carbonic oxide gas.

If alumina in the form of granulated corundum is mingled with the carbon in the electric path, aluminium is rapidly liberated, being in part carried off with the escaping gas, and in part condensed in the upper layer of charcoal. In this way are obtained considerable masses of nearly pure aluminium, and others of a crystalline compound of the metal with carbon. When, however, a portion of granulated copper is placed with the corundum an alloy of the two metals is obtained, which is probably formed in the overlying stratum, but, at the close of the operation, is found in fused masses below. In this way there is got, after the current has passed for an hour and a half through the furnace, from 4 to 5 pounds of an alloy containing from 15 to 20 per cent of aluminium, and free from iron. On substituting this alloy for copper, in a second operation, a compound with over 30 per cent of

* Read Sept. 17, 1885, before the Halifax, N.S., Meeting of the American Institute of Mining Engineers.

aluminium is obtained. Already the small experimental plant, with a 30 horse-power dynamo, is producing daily over 5 pounds of aluminium in the form of a rich and brittle alloy, which, by suitable additions of copper, is converted into different grades of aluminium bronze. The valuable qualities of these are so well known that it is only their great cost hitherto that has prevented their more general use in the arts. They are now offered for sale at Cleveland on a basis of 5 dollars a pound for the contained aluminium.

The reduction of silicon is even more easy than that of aluminium. When siliceous sand, mixed with carbon, is placed in the path of the electric current, a part of it is fused into a clear glass and a part reduced, with the production of considerable masses of crystallised silicon, a portion of this being volatilised and re-converted into silica. By the addition of granulated copper there is readily formed a hard, brittle alloy, holding 6 or 8 per cent of silicon, from which silicon bronzes can be cheaply made. The direct reduction of clay gives an alloy of silicon and aluminium, and with copper a silico-aluminium bronze that appears to possess properties not less valuable than those of the compound already mentioned. Even boric oxide is rapidly reduced, with evolution of copious brown fumes, and the formation in presence of copper of a boron bronze that promises to be of value; while, under certain conditions, crystals of what appears to be the so-called adamantoid boron are formed. In some cases, also, crystalline graphite has been produced, apparently through the solvent action of aluminium upon carbon.

Remarkable results are got by alloying small quantities of aluminium with an admixture of copper and nickel. One of these compounds, designated as Hercules metal, broke with a strain of 111,000 pounds to the square inch, with an elongation of 35-100ths, while a 10 per cent aluminium bronze broke with 109,000 pounds. An addition of from 2 to 3 per cent of aluminium to brass greatly increases its tensile strength, and renders it less susceptible to oxidation. While 15 or 20 per cent of aluminium with copper yields a brittle compound, an addition of 10 per cent of copper gives to pure aluminium a great increase of hardness and tenacity, forming an alloy that may have a wide application. It may be added that the difficulties in the way of getting together the reduced aluminium without the aid of the copper promise to be overcome at an early day, so that we may expect the cheap production of such alloys and of pure aluminium.

The Messrs. Cowles, in their later work, have been aided by the chemical skill of Prof. C. F. Mabery, now of Cleveland, who is associated with them in one of their patents. These now cover not only the reduction of aluminium, silicon, and boron, as described, but the extraction of manganese, magnesium, and the alkaline metals by the electric furnace. I had the pleasure of hearing Prof. Mabery give the first scientific notice of this discovery before the American Association for the Advancement of Science, at Ann Arbor, August 28th, and then spoke of the early results of Deville and those of Debray on aluminium and its alloys, having myself witnessed many of the experiments of both of these chemists thereon. I also insisted that the importance of this new instrument that the Messrs. Cowles have placed in the hands of chemists, for producing and controlling degrees of temperature never before obtained, can scarcely yet be estimated, either in its economic or its scientific aspect. This heat of the furnace realises the dream of the alkahest, or universal solvent of the alchemists, and he who can rightly use it will be worthy of the ancient title of *Magister Magnus in igni*.

I may add that, through the courtesy of these gentlemen, I have since been enabled to spend two entire days in their experimental works at Cleveland, with the Brothers Cowles and Professor Mabery, when they explained to me several points not yet made public, and allowed me to direct experiments with one of their furnaces. The fusion of quartz and the reduction of silicon without the presence of copper was repeated; also the reduction of boron and the formation of boron bronze, with many other interesting experiments. I then suggested trials for the reduction of titanium, both from rutile and from titanic iron ore, which will probably soon be made.

The present plant at Cleveland is but a first experimental one, and has only been in operation a few months. The Cowles Electric Smelting Company has secured a large water-power at Lockport, New York, and a dynamo-electric machine of 125 horse-power is now building for them at the Brush Works in Cleveland, which will soon be in operation at Lockport, and will permit the establishment of the electric furnace on a larger scale. A series of experiments of the products got by this remarkable discovery is, by the courtesy of these gentlemen, placed before the members of the Institute.—*Canadian Record of Science* (vol. ii., No. 1.)

ANALYSES OF SOME IRON ORES.

By J. CUTHBERT WELCH.

(Continued from page 53.)

II. *Limonite.*

Formula = $2Fe_2O_3.3H_2O$.

This requires—

Fe_2O_3	85·56
H_2O	14·44
	100·00

1. From Weardale, Durham. Compact, botryoidal, and with a radiating structure. Lustre in places shining and in others dull. Brittle, with a conchoidal fracture. Colour blackish brown. Streak brownish red. Three determinations of its specific gravity gave 3·410, 3·403, and 3·422; mean = 3·412. Metallic iron = 99·753 per cent.

Data.

Iron—

0·25 grm. required 14·37 c.c. potassium bichromate.

Hygros. water—

5 grms. gave 0·1078 grm. hygroscopic water.

Combined water—

5 grms. gave 0·7256 grm. combined water.

Silica—

5 grms. gave 0·0248 grm. silica.

Sulphur—

5 grms. gave 0·0918 grm. barium sulphate.

Magnesia—

5 grms. gave 0·0109 grm. magnesium pyrophosphate.

Phosphorus—

4 grms. gave 0·0008 grm. magnesium pyrophosphate.

Arsenic—

4 grms. gave 0·0104 grm. magnesium pyroarsenate.

DETERMINATION OF WATER IN CRYSTALLINE BORIC ACID.

By H. GILBERT.

STOLBA'S process for the determination of water in boric acid is inapplicable in presence of sulphuric acid, which occurs in Tuscan and Californian samples, and of ammonia, which is met with in the former. In such cases the author introduces the boric acid into milk of lime, evaporates, and ignites. He places 1·5 grm. of commercial quicklime in a platinum capsule, ignites with the blast until the weight is constant, adds then 10 c.c. of water, stirs 2 grms. boric acid into the milk of lime, and evaporates to dryness. He heats then at first with a small, and then with a large, flame, and finally—to expel the carbonic anhydride which has been taken up—he ignites with the blast for five minutes. The loss of weight is water and ammonia, which is determined separately and deducted.—*Repertorium Anal. Chemie* (vol. v., p. 374).

TITRATION WITH LACMOID AS AN INDICATOR.

By G. BURKHARD.

THE author has carried out a series of comparative titrations to determine the applicability of lacmoid as compared with litmus. In the titration both of caustic and carbonated alkalies and earths, the results of both were alike. Lacmoid is permanent in boiling solutions, acid or alkaline. On the slightest excess of acid or alkali the change of colour ensued with great distinctness, lacmoid being apparently more sensitive than litmus. In lime solutions it indicates 0·00014 per cent by volume of lime, and in soda solutions 0·00025 of soda. It has the advantage over litmus in permanence, in the purity of the red and blue colours, and in the abruptness of the change. As compared with other sensitive indicators it has the advantage of universal applicability.—*Chemische Industrie*, from *Schädler*.

THE ANALYSIS OF COMMERCIAL SAMPLES OF IODINE.

By G. WEISS.

THE author received some samples which by appearance might contain 99 to 99·5 per cent of actual iodine, but which on titration showed more than 100 per cent. They were found to be contaminated with bromine to the extent of 3 per cent. For the separation and determination of iodine, bromine, and chlorine, Weiss heats the substance in a current of air with an excess of a moderately strong solution of ferric sulphate, receives the iodine in a strong solution of potassium iodide, and titrates it with sodium hyposulphite. The residue is cooled, mixed with potassium permanganate, heated to 50° to 60°, and treated with a current of air. The bromine evolved is received in ammonia and determined by titration, or, preferably, gravimetrically as silver bromide. The chlorine is then calculated from the difference.—*Repert. Anal. Chemie.*

A DEFECT IN THE VOLUMETRIC DETERMINATION OF CHLORINE BY MOHR'S PROCESS.

By G. BISCARO.

IF nitrates, especially those of the alkalies and earths, are simultaneously present, the precipitation of the red silver chromate often takes place too late, whether because such nitrates form double salts with silver nitrate which are not precipitated by potassium chromate, so that a decided excess of silver becomes necessary, or that the silver chromate already formed is slightly soluble in those waters. This observation is of especial importance in determinations of chlorine in organic bodies which have been ignited with lime and then dissolved in nitric acid. Besides the nitrates other salts seem to interfere in a similar manner in Mohr's process.—*Ann. de Chim. Med. Farm. und Chemische Industrie.*

CONTRIBUTIONS TO THE KNOWLEDGE OF SAMARIUM.*

By P. T. CLEVE.

(Continued from p. 47).

Bromoaurate of Samarium, $SmBr_3+AuBr_3+10H_2O$.

This compound crystallises in large, brilliant, and well formed thick rhombic tablets of a brown, almost black, colour. It is very deliquescent.

1·2964 grm. gave 0·6340 grm. Au+$Sm_2{}_3SO_4$, which left after washing with water 0 2527 grm. Au.

0·8427 grm. was treated with sulphurous acid and gave 0·1633 grm. Au and 0·9176 grm. AgBr+0·0186 grm. Ag.

Ferrocyanide of Samarium and Potassium, $SmKFe6CN+5H_2O$ (or $3H_2O$ dried at 100°).

A solution of ferrocyanide of potassium yields nitrate of samarium a light coloured, dirty yellowish, finely divided and non-crystalline precipitate, which, on washing, passes through the filter-paper. The precipitate was dried in the air and then analysed.

0·8548 grm. lost on heating to 100° 0·0460 grm. The dried substance was then carefully ignited, and the residue dissolved in HCl. The solution yielded with NH_3 0·4465 grm. $Sm_2O_3+Fe_2O_3$ and the filtrate 0·1133 KCl.

In per cent—

	Air-dried.	Dried at 100°.	Calculated. Formula with $5H_2O$.	Calculated. With $3H_2O$.

The numbers found do not agree sufficiently well with those obtained by calculation, so that there may be some doubt as to the exact amount of water.

Platinocyanate of Samarium, $2Sm(CN)_3+3Pt(CN)_2+18H_2O$.

This compound was obtained by slowly evaporating, over oil of vitriol, the solution resulting from the double decomposition of platinocyanide of barium and sulphate of samarium. The compound forms beautiful tolerably large prisms, which appear yellow by transmitted and blue by reflected light. It is stable in the air, and looses at 110° 16·33 per cent H_2O or 14 mols. (= 16·57).

The analysis, already published,* gave in per cent:—

Periodate of Samarium, $SmIO_5+4H_2O$.

A solution of periodic acid gives with a solution of the acetate or of the nitrate of samarium a voluminous amorphous precipitate, which, after a short time, changes into small colourless or light yellow prisms with wedge-shaped ends. The salt does not lose water at 100°. Heated over a gas-burner it gives off violet vapours, turns black, and finally leaves a cinnamon-coloured residue of an oxyiodide.

* *Journal of the Chemical Society*, 1883, p. 368.

I. 0·5231 grm., treated in the same manner as the iodate, gave 0·2931 grm. AgI and 0·2064 grm. Sm_2O_3.

II. 0·3812 grm. gave 0·2113 grm. AgI and 0·1484 grm. Sm_2O_3.

Hyposulphate of Samarium.

The solution obtained by double decomposition from the sulphate of samarium and the hyposulphate of barium yields on evaporation over oil of vitriol a thick liquid, which deposits the hyposulphate in long slender needles, which were not analysed, as they could not be perfectly freed from the thick mother-liquor.

(To be continued).

Micro-chemical Demonstration of Brucine and Strychnine in the Seeds of the Strychnaceæ.—O tto Lindt (*Schweiz. Wochenblatt Pharm.* and *Chem. Zeitung*).—If to a thin section of the seed, freed from fat by means of petroleum ether, there is applied selenic acid mixed with ½ to ¼ part of nitric acid (sp. gr. 1·2), if brucine is present the cell-walls containing it are quickly coloured bright red, passing into orange and yellow. For the detection of strychnine the author uses a solution of cerium sulphate and sulphuric acid. Before applying it the sections must be freed from brucine, glucose, fat, &c., by repeated treatment with petroleum ether and absolute alcohol, the latter of which dissolves brucine. The reagent colours cell-membranes a violet blue, which soon disappears.

Adulteration of Ether with Petroleum Ether.—Vitali (*Orosi*).—The author treats a moderate quantity of ether with strong sulphuric acid in a graduated cylinder. The ether is taken up by the acid, and if it is pure there remains only a homogeneous liquid. If there remains a supernatant stratum he tries whether its volume is reduced by treatment with more sulphuric acid. A portion of the supernatant liquid is then removed with a pipette and tested with a trace of iodine, which dissolves in petroleum ether with a violet colour, but with a brownish yellow in ether. B. J. Borrigter (*Archiv der Pharmacie*) mentions that ether often contains hydrogen peroxide. Such ether liberates iodine from potassium iodide and colours a portion of potassium hydroxide yellowish brown. On distilling such ether there occurs at last an explosion with the formation of a white vap ur. Aldehyd is always found in such ether along with hydrogen peroxide. Such samples, after prolonged treatment with potassa, give no colouration with a fresh portion of potassa, and cease to decompose potassium iodide. In this manner ether may be purified from hydrogen peroxide, aldehyd, and water. Borrigter finds more hydrogen peroxide in ether which has been kept in bottles with glass stoppers than in such as have been corked.

NOTICES OF BOOKS.

Outlines of Organic Chemistry. By H. FORSTER MORLEY, D.Sc. London: J. and A. Churchill.

THIS work takes a higher aim than the chemical text-books and "manualettes" which have of late years become so alarmingly numerous. We notice, in the first place, with much pleasure, that the author is not enamoured of the examinational system which at present dominates our schools and colleges. He writes in his Preface:—"The requirements of students working for examinations have, unfortunately, compelled some departure from the plan which seems to me most suitable for teaching, because it was necessary that the book should include every substance upon which a student might expect to be examined." He also expresses the opinion—a perfectly correct one unless we are much mistaken—"that it is desirable for the beginner to go through a short course of 'preparations,' although they are not encouraged by our examination system." The strings of questions and the collections of examination papers which figure so largely in many of our chemical text-books are here happily wanting.

Concerning the methods of teaching chemistry Dr. Morley lays down, in the main, very sound principles. He criticises the usual arrangement of books on Organic Chemistry. This arrangement he characterises as "didactic and deductive: a preliminary chapter on formulæ and classification, with general descriptions of the various kinds of reaction, is followed by chapters exhibiting special cases of these general laws. But it ought not to be supposed that the student is acquainted with the properties of a score or two of organic substances of which he has never heard the names." This method he further denounces as unscientific. "Chemistry is an experimental and inductive science, not to be studied like Euclid." Our national misfortune is that, until lately, the teaching not merely of chemistry, but of all the natural and experimental sciences, has been entrusted to men who have merely a book-knowledge of the subjects. Even yet we fear it would be possible to discover schools where the attempt is made to teach chemistry and physics without apparatus. Some years back we had occasion to mention the case of two students (?) who had taken honours, the one in chemistry and the other in physiology. The former had never even cleaned out a test-tube, and the latter had never looked through a microscope.

A second method, which the author pronounces scientific and excellent, is to begin with the description of things well known, such as sugar, starch, vinegar, &c., and after the study of these proceed to examine the various products which can be derived from them. This method we should like to see fully developed.

He adopts, however, a third method. He undertakes "to describe compounds in the order in which they may be synthetically produced, so that each compound should be a product of the one before and a producer of the one after." His reason for adopting this order is his belief that "a correct appreciation of structural formulæ, and the power to judge whether a given formula be correct or incorrect, is essential if chemical industry is to make any headway in England. The dogmatic teaching of structural formulæ has turned the hearts of many chemists altogether; the result has been that original research has ceased for want of original ideas, and the decline of chemical industry is the result."

This is certainly a novel way of accounting for the relative paucity of chemical investigations in England, and for the decay of our chemical manufactures, and one to which we are by no means prepared to give an unqualified assent. In our opinion the mischief has several sources. Perhaps the main one is that original ideas and original research count for nothing at the repeated examinations for which the English student has to be ever and anon preparing, and are therefore neglected in favour of something which will "tell." We have always been of opinion that in a multitude of English chemical text-books, and in the teachings of certain colleges, structural formulæ have played a very prominent part, but the harvest of research has been by no means proportionate.

Dr. Morley insists upon a truth much overlooked. He remarks that chemical substances do not form a chain, but a tree, and that it is hence impossible to arrange them in a linear series.

Our general impression of this work is decidedly favourable, and we believe that it will be found very useful to students; but, until we dethrone the tyrant Examinationism, the ablest professors, the best manuals, and the most ample appliances will not suffice to place us in the van of scientific progress.

CORRESPONDENCE.

MILK-ANALYSIS.

To the Editor of the Chemical News.

SIR,—In issuing a second edition of my "Treatise on Milk-Analysis," I feel called upon to make known my views on the present condition of milk-analysis in this country, and as one of my earliest papers on the subject was published in the CHEMICAL NEWS about fourteen years ago, I send you my present contribution.

In constructing a system of milk-analysis, I was mindful that milk is a complex organic fluid, and that its constituents must be fragile, and that in submitting it to analytical processes there was the danger of setting up decomposition.

When I sought to obtain the total milk-solids by the process of evaporating off the water and drying the residue, it was necessary to guard against mistaking the actual water existing in the milk for water which might arise as a decomposition product. Under the influence of this idea I was led to seek the quickest way of obtaining the total solids, and found that a three hours' exposure to a temperature of 100° C. in a suitable platinum vessel, will deprive 5 grms. of milk of all its water, and reduce it to the condition of dry milk-solids. Very numerous experiments warrant me in asserting that the total milk-solids obtained in that manner are a constant quantity, which, in point of constancy, will challenge comparison with the best constants in analytical chemistry. My system of milk-analysis is based upon this constant, and rests on it as on a rock.

For some years milk-analysis, very much in the form in which I had cast it, was much practised in this country, and has been resorted to in the proceedings under the Acts for the suppression of the adulteration of food.

Many attempts have been made to discredit it, especially within the last four years; and its author, as is notorious, has, for the most part, abstained from taking any part in the discussions which have arisen.

There are two chief causes why, just at the present time, milk-analysis has declined in public estimation. One of these causes is that those analysts who practise it have not adhered with sufficient closeness to the details of the method as laid down by its author. The other cause is the appointment of the authorities of Somerset House as a sort of court of reference in cases arising under the Sale of Food and Drugs Act.

According to the directions given in the "Treatise," a milk-residue is to be obtained by drying up 5 grms., or 5 c.c. of milk, for three hours; and I lay particular stress on the full time being allowed. In the pages of *The Analyst* for the year 1882, Mr. Hehner describes the method to consist in drying 5 grms. of the milk for two and a half to three hours. Sometimes analysts alter the

scale, taking 10 grms. instead of 5 grms. for the solid residue; and even the temperature of drying has been altered—instead of 100° C., I have known 110° C. to be employed. The substitution of the water-oven for the water-bath is sometimes made.

I disapprove of all these alterations, and have to remark that, under such treatment, discrepancies are inevitable.

In my treatise "the solids not fat" are arrived at by the arithmetical operation of subtracting the quantity of fat from the quantity of total solids. It may seem a small point—to insist upon that manner of arriving at the "solids not fat" in preference to the direct operation of weighing the "solids not fat;" but I believe that much uncertainty has arisen from the substitution of the direct for the indirect measurement of "solids not fat."

With regard to the determination of the fat, I do not see any reason to alter the method laid down in my book; and I would make the remark, that the extra 0·2 per cent of fat with which the employment of the Soxhlet apparatus is credited, may possibly be a product arising from the metamorphosis of the caseine.

In constructing the system of milk-analysis, I had before my eyes the necessity that the system should be practicable as well as logically consistent. I felt, too, that simplicity and rapidity of execution would commend it. That it is simple beyond compare and that it is quick is a matter of common knowledge.

In three and a half hours a good operator is able to make the whole analysis, and fill up the following form:—

In 100 c.c. of milk—

	Grammes.
Total solids	$= x$
„ fat	$= y$
Solids not fat (calculated)	$= x - y$
Ash	$= z$

In reading the criticisms of the milk-analysis—I hope I may be pardoned for saying so—I have been amused. My critics appear to imagine that milk is a fluid of simple composition, and that in point of simplicity it resembles an aqueous solution of two or three simple mineral salts; and appear to regard paying attention to the complexity of milk as an unscientific procedure. My critics, who look upon milk as a comparatively simple fluid, recommend complicated and tedious analytical processes which they say are scientific. I, who hold that the composition of milk is pre-emiently complex, resort to the simplest of analytical methods.

The various suggestions which have been made for the modification of milk-analysis—the suggestion to dry for six hours instead of for three or three and a half hours; the suggestion to mix the milk with sand, or to spread it out on blotting-paper; the suggestion to submit the "solids not fat" to two dryings instead of one; the suggestion to resort to the Soxhlet digestion with ether, instead of the simpler treatment; all these suggestions tend in one direction, viz., towards the destruction of the "solids not fat," which when milk analysis left my hands fourteen years ago, were shielded from all harm with most zealous care. The adoption of these suggestions at once lowers the milk standard from 9·3 to 8·5; and the principles which dictate the adoption of these suggestions degraded milk-analysis to the condition in which I found it before the year 1871.—I am, &c.,

J. Alfred Wanklyn.

London, January 25, 1886.

THE INSTITUTE OF CHEMISTRY.

To the Editor of the Chemical News.

Sir,—Being one of those who have passed the examination for the A.I.C., I should like to say something about it from our point of view. As probably will be expected, I am entirely opposed to persons being admitted simply on evidence of fitness. I fail entirely to see then what difference there would be between the Institute and the Chemical Society. It is well known that in the latter there are a fair number who, from the amount of their knowledge of chemistry, ought never to be there. Moreover, if the Institute intend to apply for powers to make the Associateship a necessary qualification for practising as an analytical chemist, I think they will find that the authorities will scarcely like the idea of "evidence of fitness."

But, whilst completely opposed to this, I think that the condition of having had a three years' college course, and having passed examinations in that college, might with great advantage be abolished. It might perhaps be replaced by requiring three years at a college, or with an analytical chemist of known standing, as suggested at the meeting in Manchester. But if this was done it seems to me that there must be added some kind of theoretical examination. Probably the best way would be to make it a condition that the candidate for the practical examination should present certificates of having passed in certain subjects of the Science and Art Examinations, and having attained a certain standard in them, the subjects and standard being of course fixed by the Council. These examinations are held in so many places all over the country, and the fees are so small, that it would not be difficult for anybody to take them.

Besides this, however, the practical examination needs a thorough reform in its system. The present method is that each of the local examiners sets what he pleases, and himself examines the papers. Now under these circumstances it is impossible that the candidates at the different places should be treated alike, for examiners, like other people, are human, and differ very much in the standard they expect, and what some reckon trifling errors others reckon great blunders. Moreover, some set a much more difficult examination than others, which of course tells greatly. The analyses, &c., to be made ought to be decided by the whole of the examiners together, the same things given all over, and when finished the papers should be examined by two or three of these examiners, and a list published of the successful candidates. If this were done there would, I expect, be less complaining about the practical examination.

At the same time it is to be hoped that, if anything of this kind be adopted, the examiners will not fall into the error so frequent among examiners, now-a-days, of giving a stiff catch examination. The reason a great many people are getting disgusted with the examination system is because so many of the papers, at the present time, are set to find out, not what the candidates know, but what they *do not* know. I am quite sure that it is a far fairer test of knowledge to give a comparatively easy paper, and then, of course, expect a somewhat higher standard.—I am, &c.,

Cyclops.

THE INSTITUTE OF CHEMISTRY.

To the Editor of the Chemical News.

Sir,—I sincerely trust that the Council of the Institute of Chemistry will not decide upon the retrograde, and probably suicidal, step of abolishing the entrance examination;—a step which would be extremely unfair to those Fellows of the Institute who waited until the present examination became a *sine qud non* for admission, in the belief that the value of a qualification obtained by examination is far higher than that of a title procured without any real test of ability whatever, and that, in future, the qualification of F.I.C. would only be obtainable by examination. Abolition of the examination would roughly undeceive these Fellows, who in such a case would, I think, do well to agitate for the return of their entrance-fees and subscriptions.

Such a step would at one blow destroy the *raison d'être* of the only Association which has done anything in the

direction of giving professional chemists a more definite position than they have hitherto occupied. In writing thus I have not forgotten the existence of the Society of Public Analysts, which, excellent in its way, does *not* supply what is wanted.

An officially recognised Examining Body, whose diploma shall be required by Law to have been obtained by every man desirous of practising as a consulting and analytical chemist. This is our urgent requirement. Lawyers, physicians, surgeons, and even drug-sellers, have to undergo examinations: why should professional chemists be, in this respect, upon a lower level? As things are at present there is nothing whatever to prevent any linen-draper's assistant, merchant's clerk, or grocer's shop-boy from setting up in practice as an analytical chemist.

By making an examination an indispensable condition of admission to Fellowship after the first 36 months, the Institute of Chemistry took a step in the right direction, though much yet remains to be done. Surely it would be madness for the Council to undo the work performed. Let them rather strain every nerve to procure an Act of Parliament. This, however, would certainly not be facilitated by doing away with the crucial test to which candidates for admission to Fellowship now have to submit themselves.

The feebleness of the arguments brought forward in favour of the abolition of this test of ability is really amazing. Does it not appear as if those who don't belong to the Institute, and wish to, desire to shirk the examination? Perhaps this is a feeling common to all who have an ordeal of this kind looming in the future.

It is somewhat curious that so much has been said about the time occupied in preparing for and submitting to the examination. *Of course* an examination takes up a few days, and the loss of nearly a week may be no small matter to a young practitioner. Still what one can do, another should be able to manage; and the qualification, *so long as it is procurable only by the severe test of a stiff examination*, is decidedly worth a little trouble and expenditure of time.

One of your correspondents referred to the Institute of Civil Engineers. That is undeniably a fine institution, but its existence does prevent the possibility of a man who has not had a day's training in his life sticking "C.E." after his name, and setting up in practice as a civil engineer. This kind of thing, whether among engineers or among chemists, should not be possible; and the much maligned and scoffed at Institute of Chemistry has, so far, worked in the direction of putting an end to such a condition of affairs among chemists. Let us hope that its Council, in place of making the great mistake of annulling all its past work, will strive to reach the goal which is so desirable and necessary, for the sake of all practising professional chemists.—I am, &c.,

E. F. M.

MICROSCOPIC WRITING.

To the Editor of the Chemical News.

Sir,—Our attention has been called to a statement made in your paper, when reporting a meeting of the Manchester Literary and Philosophical Society (Chemical News, vol. liii., p. 33), that Mr. Webb, who exhibited the microscopical writing-machine at the Exhibition of 1862, died some ten or fifteen years since. We should be very much obliged, therefore, if in your next issue you would contradict this statement, as Mr. Webb is still alive, and continues to do for us these remarkable microscopic writings, which we are continually selling; and if any of your readers wish to have any further information about them we shall be pleased to supply it on their communicating with us. The announcement of Mr. Webb's death is calculated to injure both him and ourselves if left to stand uncorrected.—We are, &c.,

W. Watson & Sons.

313, High Holborn, London, W.C.

CHEMICAL NOTICES FROM FOREIGN SOURCES.

Note.—All degrees of temperature are Centigrade unless otherwise expressed.

Comptes Rendus Hebdomadaires des Séances, de l' Académie des Sciences. Vol. cii., No. 3, January 18, 1886.

Electric Spectrum peculiar to the Rare Earths of the Terbium Group.—Lecoq de Boisbaudran.—See p. 63.

Considerations relating to the Electric Illumination of Lighthouses.—F. Lucas.—The author points out the defects of the arc-light and recommends an incandescence lamp with a special modification for the absorption of traces of oxygen remaining in the glass globe.

The Active Principle of the Comma Bacillus, regarded as the Cause of Death and of Immunity.—J. Ferran and I. Pauli.—The authors infer from four series of experiments on guinea-pigs that the comma bacillus when dead confers an immunity which enables animals to resist the effects of the living bacillus. The active principle of the bacillus, insolated by known methods, confers an immunity which enables the animal to resist the effects of the living microbion, and *vice versa*. According to these authors the cause which determines immunity and the cause which induces death are one and the same, essentially chemical in their nature. Hence immunity is merely a case of habituation which may be obtained by purely chemical agents.

Lengths of Undulations hitherto not recognised.—M. Langley.—Until a very recent date the limits of the known spectra from all sources, celestial or terrestrial, were from 2000 to about 10,000 of Angström's scale, that is from 0·0002 to 0·0010 m.m., and even last year an authority no less competent than M. Becquerel maintained that the most extreme radiations whose existence had been experimentally demonstrated did not reach a wave-length of more than 0·0015 m.m. The author's researches have extended to the sources of heat comprised between 100° and −2°, the latter radiating upon bodies still colder. The smallest value corresponding to the maximum heat in the spectrum of melting ice is in all cases greater than 50,000 of Angström's scale. The radiations whose lower limit Newton found at 0·0007 m.m. have been extended to 0·0150 m.m., that is to more than twenty times Newton's limit, so that the great gap which existed between the lowest known vibration of light and the highest known vibration of sound has been in part filled up.

Action of Antimony Sulphide upon Potassium Sulphide.—A. Ditte.—If hydrated antimony sulphide is treated with a strong solution of potassium monosulphide much of the former is dissolved, and the liquid, if evaporated in the presence of an excess of alkaline sulphide, deposits large octahedral transparent crystals of a pale yellow—$2KS,SbS_3$. Cold water splits them up, giving an orange deposit and dissolving potassium sulphide. If a weaker solution of potassium sulphide is saturated with antimony sulphide the above crystals no longer appear, but in their stead a compound less rich in alkaline sulphide and sparingly soluble in water. This solution on evaporation *in vacuo* forms light red prismatic crystals easily affected by light.

A New Synthesis of an Inactive Borneol.—G. Bouchardat and J. Lafont.—The authors have effected this synthesis by setting out from terebene or inactive camphene, which they have transformed by the direct fixation of an organic acid into a borneol ether. The latter on saponification yields the inactive borneol in question.

January 25, 1886.

Observations relating to M. Langley's Paper on Wave-lengths hitherto not recognised.—H. Becquerel.—In the *Comptes Rendus* of January 18th occurs a

paper by M. Langley, who ascribes to the author a statement that "the most extreme radiations whose existence has been experimentally demonstrated do not reach a wave-length exceeding 0·0015 m.m." M. Becquerel has never put forward such an opinion, for the limit at which observations come to a stop depends essentially on the nature and the sensitiveness of the methods employed to show the presence of the invisible ultra-red radiations. In the *Comptes Rendus* for September 1st, 1884, he gave lengths of the principal rays and bands of the ultra-red solar spectrum, determined by means of a grating, as far as 0·001880 m.m., numbers which agree with those given by M. Langley for the same regions. The method of observation founded on the phenomena of phosphorescence does not yet enable us to reach as far as does M. Langley's bolometer, but within the limit indicated above it gives a much greater delicacy of details.

Transfer of Copper through a Gaseous Stratum, and the Direct Combination of Copper and Nitrogen.—R. Blondlot.—This paper will be inserted at some length.

On Certain Properties of Antimony Sulphide.—A. Ditte.—The double potassium and antimony sulphides described in the author's recent paper may also be obtained with anhydrous antimony sulphide. Between antimony chloride and hydrogen sulphide on one side, and antimony sulphide and hydrochloric acid on the other, there are produced inverse and reciprocal actions giving rise to chloro-sulphides, hydrochlorates, &c.

Reagent for Detecting the Acid Function of Feeble Acids.—R. Engel.—This paper will be inserted in full.

Composition of Wine-Brandies.—Ch. Ordonneau. In true brandies distilled from grape-juice the author finds normal butylic acid present. In the alcohols of grain, beet-root, and potatoes, instead of butylic acid there is found the isobutylic, without a trace of normal butylic acid. This isobutylic acid, the cause of the disagreeable odour and taste of these alcohols, is not formed if fermentation is affected by the elliptical ferment of wine, whilst it is always present if beer-yeast is employed.

Journal für Praktische Chemie.
New Series, Vol. xxxii., Part 11.

Researches from the Chemical Laboratory of the University of Kasan.—This consists of the conclusion of a paper by J. Kanonnikoff, on the refractive power of chemical compounds.

Magnetic Circular Polarisation of Compounds in Relation to their Chemical Constitution, with Remarks on the Preparation and Specific Gravity of the Bodies examined (conclusion).—W. H. Perkin.—This extensive memoir, which is illustrated with a number of diagrams, does not admit of useful abstraction.

On Triphenyl-acetic Acid.—K. Elbs and E. Tölle.—The authors describe the salts of this acid, its sulphonation, its oxidation, and the by-products of the action of trichloracetic acid upon benzol in the presence of aluminium chloride.

On a Dimethyl-naphtho-chinoline.—J. Hastings Reed.—The compound in question, $C_{15}H_{13}N$, is a white, crystalline body, readily soluble in alcohol and ether, fusible at 126° to 127°, and volatile at above 360°.

Zeitschrift für Analytische Chemie.
Vol. xxv., Part 1, 1886.

A Bead Tube for the Absorption of Gases.—A. Emmerling.—(*Chemiker Zeitung.*)

Sulphuric Acid Bath.—A. Kalesinsky.—All these three papers require the accompanying figures.

Cutting Thick Glass Tubes.—An anonymous writer in *La Nature* wraps round the tube an iron wire of 0·5 m.m. in thickness, introduces it into an electric current of sufficient strength to ignite the wire, and drops a little water uhon the glass by the wire.

Air-tight Corks.—An anonymous writer in the *Chemiker Zeitung* proposes to soak them for some hours in a solution of 15 grms. gelatin and 24 grms. glycerin in ½ litre of water at 44° to 48° and then to dry them. If they are to resist acids they are introduced into a mixture of 2 parts vaseline and 7 parts paraffin at 40°.

Reagent for Alkaline Substances.—Otto Schweissinger (*Chem. Central-Blatt.*)—Two drops of "iodised tincture of galls" (the preparation of which is not given) give a transitory rose colour with all alkalies and alkaline earths, their carbonates, bicarbonates, borates, and phosphates, if soluble in water. In this manner 1 part potassium carbonate can be recognised in 100,000 parts of water.

Development of Hydrogen Sulphide.—Kübel (*Archiv der Pharmacie*)—When hydrogen sulphide is only required at intervals the author washes the iron sulphide, after use, with water, and preserves it under a stratum of glycerin.

Production of Hydrobromic Acid.—Ad. Sommer.—From the *Journal of Society of Chem. Industry.*

Quantitative Analysis by Electrolysis.—Alex. Classen and others.—The notes will be reproduced at some length.

The Gravimetric Determination of Manganese.—C. Holthoff and C. Reinhardt.—A discussion on Wolff's method of separating manganese from lime and magnesia.

Determination of Sulphurous Acid in its Combinations.—W. B. Giles and A. Shearer.—From the *Journal Soc. Chem. Industry.*

Determination of Bromine in presence of Excess of Chlorine.—A. Cavazzi (*Gazetta Chimica* and *Chemiker Zeitung.*—Already noticed.

Formation of Chloroform Hydrate.—G. Chancel and F. Parmentier.—From the *Comptes Rendus.*

Distinction between Ortho-, Para-, and Meta-diamines.—E. Lellmann.—From *Liebig's Annalen.*

Determination of Halogens in Organic Substances.—C. Zulkowski and C. Lepèz (*Monaths' Hefte f. Chemie*).—An improvement upon the author's method (vol. xxiv., p. 605) of effecting combustion with oxygen in presence of platinised quartz.

Determination of Tannin.—C. Councler and J. von Schrœder.—The report of a commission for revising Löwenthal's process. The principal results will appear at the earliest opportunity.

Proportion of Alcohol to Glycerin in Beer.—E. Egger.—The author finds that Borgmann's method devised for sweet wines is also available for the analysis of beers.

Examination of Sugar.—A. Vogel (*Bayr. Industrie u. Gewerb-Blatt*).—According to the author beet-sugar (betose) can be distinguished from cane-sugar (true saccharose) by a trace of nitric acid, demonstrable by means of indigo or diphenylamine, as well as by a quantity of ammonia, determinable by the Nessler test. Practical men have observed that a solution of beet-sugar coloured with extract of indigo is decolourised on evaporation, which is not the case with cane-sugar.

Detection of an Admixture of Anhydrous Glucose in Cane-Sugar.—P. Casamajor.—From the CHEMICAL NEWS.

Adulteration of Pepper.—C. Neuss (*Pharm. Zeitung*).—If ground pepper is covered with strong hydrochloric acid all the particles, save the small blackish fragments of the shell, take an intense yellow colour. The editor remarks that certain other liquefied vegetable tissues take a yellow colour with hydrochloric acid.

Determination of the Value of Zinc Powder by the Hydrogen evolved with Acids.—H. N. Morse.—This illustrated paper is taken from the *American Chemical Journal* (vii., 1).

Flux for opening up Basic Silver Ores.—Stone.—The author uses a mixture of 9 parts soda, 3 parts borax, 1 part tartar, and uses two parts of this mixture to one part of ore. If sulphur is present a few iron nails are added.

Testing Papers.—W. Herzberg.—The author determines the resisting power of the paper with Hartig-Reusch's apparatus. Afterwards a portion of the paper, well-boiled in a flask, is submitted to a microscopical and chemical examination.

Determination of Nitrates in Human Urine.—Th. Weyl and Citron.—The authors use Schulze's method.

Apparatus for determining Urea with Sodium Hypobromite.—Ch. Doremus (*Journ. Amer. Chem. Soc.*) and G. Lunge (*Archiv f. Physiologie Pfluger*).—This paper requires the accompanying illustrations.

Detection of Blood.—Bufalini (*Ann. di Chim. Med. Pharm.*).—The blood or the watery extract of the spot is treated with a drop of tincture of iodine and a very little acetic acid. A drop of this mixture is placed upon a port-object and is repeatedly passed through a flame, whilst 8 to 10 drops of acetic acid are gradually added with a fine pipette. In this manner crystals of iodhæmine are obtained with absolute certainty in one to two minutes.

The Variation of Atomic Weights.—E. Vogel (*La Nature*).—From the circumstance that the atomic weights deduced from certain combinations regularly vary a little from those obtained from other compounds of the same element the author infers that the value of the atomic weights is variable according to certain laws. Dr. W. Fresenius suggests that such variations may be due to a constant analytical error which does not occur in case of other compounds.

Atomic Weight of Cerium.—H. Robinson.—From the CHEMICAL NEWS.

Determination of Manganese in Iron and Iron Ores.—W. Mathesius (*Chemiker Zeitung*).—The author dissolves in hydrochloric acid, oxidises the solution with bromine, and, if necessary, evaporates to dryness on the water-bath in order to eliminate silica. After re-dissolving in hydrochloric acid the whole without filtration is rinsed into a litre flask, almost neutralised with ammonia, and then mixed with an excess of zinc oxide suspended in water. The flask is then filled up to the mark with water, the contents are mixed, and half a litre is filtered through a folded filter. This portion is then mixed with a rather large quantity of quite pure ammonium chloride, then with a large excess of ammonia, and the manganese is thrown down by Wolff's method. The manganese is deposited completely and free from zinc. The precipitate of hydrated manganese peroxide is very carefully washed with ammoniacal ammonium chloride. The filter is primed with the same liquid to prevent zinc from being deposited on the fibres of the paper, which is not readily re-dissolved. Finally, to remove ammonium chloride, the filter is repeatedly washed with hot water, as otherwise a considerable loss of manganese takes place on ignition.

Detection of Morphine in Urine.—Notta and Lugan (*Journal de Pharmacie d'Anvers*).—The authors precipitate 1 litre of the sample with 100 c.c. basic lead acetate, filter, and remove excess of lead with sulphuric acid (1 : 10). The filtrate is supersaturated with ammonia and shaken up for a few minutes with 100 c.c. of hot amylic alcohol. The latter is then drawn off by means of a pipette and the morphine is transferred first to water acidulated with sulphuric acid, and from this again, after supersaturation with ammonia, to a fresh portion of amylic alcohol. The residue on evaporation is pure morphine, as may be found by the characteristic reactions.

NOTES AND QUERIES.

**** Our Notes and Queries column was opened for the purpose of giving and obtaining information likely to be of use to our readers generally. We cannot undertake to let this column be the means of transmitting merely private information, or such trade notices as should legitimately come in the advertising columns.

Utilisation of an Iron Ore.—Can any of your readers inform me if an ore containing 55 per cent iron, 17 per cent silica, and 3½ per cent alumina can be utilised?—G.

MEETINGS FOR THE WEEK.

MONDAY, 8th.—London Institution, 5.
—— Medical, 8.30.
—— Society of Arts, 8. (Cantor Lectures). "Friction," by Prof. H. S. Hele Shaw.
TUESDAY, 9th.—Institution of Civil Engineers, 8.
—— Royal Medical and Chirurgical, 8.30.
—— Photographic, 8. (Anniversary).

SELECT METHODS IN CHEMICAL ANALYSIS (CHIEFLY INORGANIC).

BY

WILLIAM CROOKES, F.R.S., V.P.C.S.,

EDITOR OF "THE CHEMICAL NEWS."

LONDON: LONGMANS, GREEN, & CO.

SCIENCE AND ART DEPARTMENT OF THE COMMITTEE OF COUNCIL ON EDUCATION.

NORMAL SCHOOL OF SCIENCE AND ROYAL SCHOOL OF MINES, SOUTH KENSINGTON.

A Course of Fifty Lectures on ORGANIC CHEMISTRY will be delivered on Mondays, Wednesdays, and Fridays, at 10 a.m., by Dr. F. R. JAPP, F.R.S., commencing on February 15th.

The Course will treat of the various Vegetable Principles (Dyestuffs, Alkaloids, &c.), with the Mode of their Extraction; the Synthesis of some of these Principles; Compounds occurring in the Animal Organism; and the Artificial Organic Compounds of Scientific or Industrial Interest.

Stress will be laid on the theoretical bearings of the various compounds, and the methods employed in determining their constitution will be described

A detailed Syllabus of the Course may be obtained on application to the Registrar.

TO CHEMICAL MANUFACTURERS.

TO BE LET OR SOLD, a Modern Works, eligibly situated near Manchester, with or without a large Plot of Land, Freehold, on a small chief rent.—Apply, A. B., CHEMICAL NEWS Office, Boy Court, Ludgate Hill, London, E.C.

THE CHEMICAL NEWS.

VOL. LIII. No. 1368.

ON RADIANT MATTER SPECTROSCOPY: NOTE ON THE SPECTRA OF ERBIA.*

By WILLIAM CROOKES, F.R.S.

I HAVE recently succeeded in getting the earth erbia in a sufficiently pure state to allow me to examine its phosphorescent spectrum without the interference which might be produced by the presence of yttria, samaria, bolmia, thulia, Yα, or ytterbia. As in the case of yttria† the spectrum is best seen when erbic sulphate is heated to redness and submitted to the electric discharge in a high vacuum. The addition of calcic sulphate interferes with the purity of the spectrum. In this respect erbia differs from samaria, as the latter earth seems to require the presence of some other metal to develope its phosphorescent properties.

The phosphorescent spectrum of erbia consists of four green bands, of which the following measurements have been taken:—

Scale of spectroscope.	λ.	$\frac{1}{\lambda^2}$.	Remarks.
9°·750	5564	3230	Approximate centre of a wide band, shading off at each side.
9°·650	5450	3367	Approximate centre of a band, narrower and somewhat fainter than the first band.
9°·525	5318	3536	Approximate centre of a narrow band, bright and moderately sharp on each side.
9°·400	5197	3702	Approximate centre of a band, similar in appearance to the first band, but brighter.

Fig. 1 shows the erbia phosphorescent spectrum drawn to the $\frac{1}{\lambda^2}$ scale.

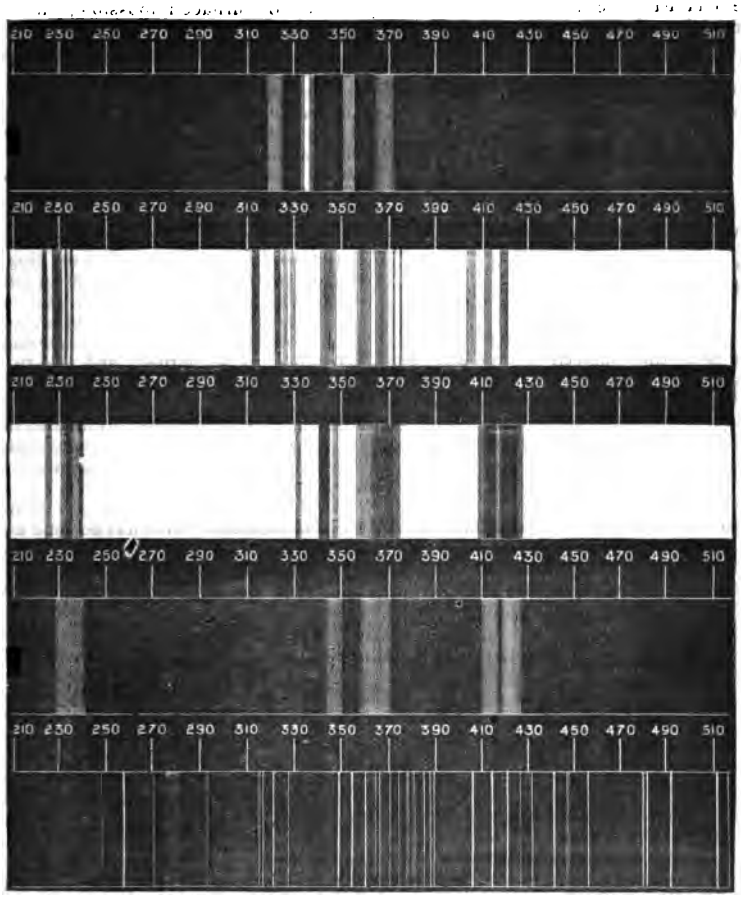

FIG. 1.

FIG. 2.

FIG. 3.

FIG. 4.

FIG. 5.

These bands do not correspond in position to any in either the yttrium or samarium spectrum. The nearest approach to a coincidence is between the first erbia green and the samarium green, but when the two spectra are examined one over the other it is seen that the samarium band is less refrangible than the erbium band.

The first green of Yα occurs midway between the first and second greens of erbia, and the second Yα green comes between the second and third erbia greens.

Pure erbia is of a beautiful rose-pink colour. When illuminated by sun or electric light and examined in the spectroscope it gives a spectrum of black lines and bands as sharp and distinct as the Frauenhofer lines. Fig. 2 shows the erbia spectrum by reflection. It is strange that

* A Paper read before the Royal Society, January 21, 1886.
† *Phil. Trans.*, Part III., 1883, p. 913 (par. 71).

this most characteristic property has been recorded by so few observers. Indeed, the only notice of it I have come across is a passing remark of Professor Clève's that "the light reflected by dry erbia shows absorption-bands."

Fig. 3 shows the absorption spectrum given by a solution of pure erbic chloride. It differs in some respects from the drawings mapped from older observations, as the absorption lines of holmia and thulia are absent. The fine group of lines in the green of the reflection spectrum is also absent in the absorption spectrum.

The spectrum of bright lines emitted when erbia is rendered incandescent in the blowpipe flame has been often observed, but the lines in this case are luminous on a fainter continuous background and are not particularly sharp, whilst the reflection spectrum consists of black lines sharply defined on a continuous spectrum.

The spectrum emitted by incandescent erbia is shown in Fig. 4.

Fig. 5 shows the characteristic lines in the spark spectrum of erbium, taken from a concentrated acid solution of erbic chloride, with a Leyden jar in a shunt circuit.

I have thought it advisable to give these five spectra of erbium, as they show how entirely different the phosphorescent spectrum is to any other spectrum given by this element.

ON THE ESTIMATION OF NITROGEN BY COMBUSTION.

By GEORGE STILLINGFLEET JOHNSON and ARNOLD EILOART, B.Sc.

MUCH has been recently written, and some work has been done, in connection with this subject, mainly with the object of suggesting improvements in the methods hitherto employed for the quantitative determination of nitrogen; partly, also, for the purpose of comparing results obtained by the two important processes introduced by Will and Varrentrapp, and by Dumas respectively.

In spite of certain statements which have been recently made to the contrary, few chemists who have worked both methods will deny that the process of Dumas is far more generally applicable than the soda-lime method. One of the outcomes of recent work with the latter process has been the addition to the soda-lime, hitherto exclusively used for estimating nitrogen as ammonia, of sodium thiosulphate, sodium acetate, or both, with the expressed object of supplying more hydrogen to the nitrogen, and thus facilitating its conversion into ammonia. This important modification of the process of Will and Varrentrapp reveals misgivings in the minds of its introducers as to the universal efficacy of the unmodified soda-lime method. It remains to be seen whether the improvements proposed will eventually extend the limits of applicability of the ammonia process to all substances.

At present, however, there are certain cases in which the soda-lime method is not available, or in which at least it can be employed only with unusual precautions; such a case is the estimation of nitrogen in coal, or the analysis of any nitrogenous compound which yields much tarry matter when submitted to destructive distillation. For the analysis of such substances the process of Dumas is certainly to be preferred.

The introduction of the Boat-method of combustion in Dumas's process has been a great improvement. Not only does this modification of the method enable us to heat the copper oxide and metallic copper in front of the tube to redness in a current of pure CO_2 before commencing the combustion, thereby vastly shortening the time required to completely expel atmospheric nitrogen from the tube and its contents, but it also renders practicable an examination of the *ash* of the substance, which is often of great importance.

One of us (CHEMICAL NEWS, vol. l., p. 191) has described such a modification of the method of Dumas, whereby also some insight may be gained as to the condition of the nitrogen in the compound under analysis, the gas evolved being collected in two portions, viz.—1st, that which escapes during the destructive distillation of the substance in CO_2; and 2nd, that which is collected whilst nitrogenous carbon, left in the boat at the close of the first stage, is undergoing combustion in oxygen, the source of this oxygen being potassium chlorate, placed in a fused condition at the back of the combustion-tube.

This process has been much used in the chemical laboratory of King's College, London, during the past year, and one object of the present communication is to describe certain improvements which have suggested themselves as results of practical experience with it.

We still employ a combustion-tube drawn out in front so as to form a delivery-tube, as at first suggested by one of us. This renders loss of gas in front of the combustion-furnace impossible, and has been found most convenient.

The metallic copper and granulated copper oxide are also retained as usual.

Instead, however, of introducing the substance under analysis into the same boat with the potassium chlorate, it was soon found more convenient to use two boats,—one for the nitrogenous substance, with a clear space of about 1 inch between it and the copper oxide; and a second for the potassium chlorate, 2 inches behind the first boat. Ignited asbestos is placed between the boats, to prevent contamination of the ash of the substance with fused KCl. The asbestos plug must not be too tightly packed, or it may create an obstruction when saturated with potassium chloride. These intervals between the boats and copper oxide enable the analyst to heat the whole of the oxide in pure CO_2 without endangering the substance to be burned, and also to expel the whole of the first portion of nitrogen from the substance without any risk of evolution of oxygen from the potassium chlorate. It has also been found advisable to collect the two portions of nitrogen in two separate measuring-tubes, in case it be desired to estimate their relative proportions accurately.

As soon as the volume of gas above the potash-ley in the first measuring tube has become constant,—no oxygen having been as yet evolved from the chlorate,—the tube containing the gas is removed, and a similar one placed over the end of the delivering combustion-tube in the mercury-trough. The potassium chlorate is then heated until sufficient oxygen has escaped to burn away the carbon in the boat and to re-oxidise the reduced copper adjacent to the boat,—a process which is easily traced by watching the glowing metal, whose temperature is raised considerably above that of the neighbouring copper oxide during its oxidation. As soon as the glow ceases, or if at any time the metallic copper in front of the combustion-tube shows signs of oxidation, the evolution of oxygen is at once arrested by removing the heat from the potassium chlorate. The behaviour of the chlorate at this stage of the process is all that could be desired. The evolution of gas is steady and easily controlled, and explosions never occur, since all combustible gases have been expelled from the tube during the first stage of the process—that, namely, of destructive distillation. After the chlorate has ceased to evolve gas, the passage of the CO_2, which passes from a Kipp's constant-generating apparatus throughout the process, is continued until the volume of the gas above the potash-ley in the second measuring-tube remains unchanged.

If the gas is measured over water it is necessary to employ boiled water for the purpose, since the potash-ley is heated by the furnace and by the absorption of CO_2, and therefore rapidly liberates any gas which may be in solution in the water.

As regards the *quantity* of potassium chlorate necessary for a combustion it has been found that, in the case of coal, ten times the weight of coal taken is sufficient,

whilst with most substances three times their weight of chlorate is ample.

Further observations have confirmed the statements made by one of us a year ago, that different nitrogenous compounds vary greatly as to the proportion of their nitrogen which escapes during destructive distillation, and also that the ratio between the two portions of nitrogen is simple and constant in each compound.

The next development was the performance of more than one determination in the same operation. Two boats, both as short as possible, and each containing a weighed portion of the substance or substances to be analysed, are placed between the copper oxide and the potassium chlorate. The front boat is of platinum, in order that its contents may readily become heated. The second boat is of porcelain, in order that its contents may not become heated too rapidly. Its distance from the first will depend on the temperature its contents will bear without decomposition; but if the interval be 3 inches it may be kept below 80° C., when the tube around the first boat is at a full red-heat. The boat for the chlorate is also preferably of platinum. Four inches of tube, partly filled with ignited asbestos, should intervene between the chlorate and the cork. When the tube cools, the asbestos plugs and the chlorate boat, now held to the tube by fused potassium chloride, must be loosened by soaking in water into which the end of the tube is dipped at a slight incline. The ash may then be weighed and examined.

As this process of cooling and extracting the chlorate-boat must be performed after each combustion, before a fresh supply of substance can be introduced between the chlorate and the copper oxide, the gain of time in performing as many determinations as possible at each operation is great, and the risk of cracking the combustion-tube by cooling and re-heating is proportionally diminished. Moreover, the air in the combustion-tube has to be expelled once only for each operation, independently of the number of determinations effected thereby. This number is of course limited by the length of the furnace, but two boats containing such a refractory substance as K_4FeCy_6 may be treated at one operation upon a 30-inch furnace.

We hope to throw some light upon the constitution of various nitrogenous compounds by a series of analyses conducted according to the process of Dumas, modified as above.

King's College, London,
February 1, 1886.

ON THE

VARIATIONS OF THE ABSORPTION-SPECTRA AND THE EMISSIVE PHOSPHORESCENCE-SPECTRA OF ONE AND THE SAME BODY.

By M. HENRI BECQUERREL.

RESEARCHES now in progress have led the author to suppose that the absorption of radiations by different substances is due to the existence of synchronous vibratory movements of the absorbed radiations,—movements which may take rise under the influence of these radiations, and which may have their seat either in the molecules of the bodies or in the intermolecular ether. In certain substances these movements give rise to phosphorescence.

This hypothesis leads to the consequence that in one and the same absorptive substance, placed in different media, the internal vibratory movements will no longer have the same rapidity, and that consequently both the absorption-spectra and the emission-epectra will be different. We may even foresee that the cause which retards the propagation of light in the interior of various media may have an influence of the same kind upon the time of the periods of the intermolecular movements, and that if we dissolve in various liquids one and the same substance presenting absorption- or phosphorescence-bands, the latter will correspond to movements so much the slower, and so much the more displaced towards the red as the indices of refraction of the solution are greater. We find thus, *à priori*, a general conclusion which has been deduced experimentally from numerous observations made by different physicists. The author has verified the generality of the fact with different substances in different solvents. Every chemical modification of the substances gives rise in the spectra to modifications which will not be examined in this paper.

The influence of the variation of the indices of refraction upon absorption is distinctly shown in solutions of one and the same body of different degrees of concentration, and observed in layers of different thickness, so that the absorption-bands always retain the same aspect. Thus for a strong solution of didymium nitrate in water, the refraction index of which corresponding to the middle of the strongest absorption-band is $n = 1{\cdot}4388$, the mean wave-length of this band is $\lambda = 579$. In the same solution diluted with water we have, for the same band, $n = 1{\cdot}3454$ and $\lambda = 574{\cdot}5$. We thus see that for solutions of different strength of one and the same body, in one and the same solvent, the absorption-bands do not occupy the same place in the spectrum, since the index of refraction varies with the concentration.

These considerations apply to crystalline media. In a double refractive crystal, giving an absorption-spectrum, the two rays have not the same indices of refraction; the absorption-spectrum corresponding to them should therefore be different, and, in this point of view, all the double refractive crystals are polychroitic. In 1866 Prof. Bunsen observed that the absorption-spectrum obtained through a crystal of didymium sulphate varies slightly if studied in polarised light according to the different directions. Mr. Sorby has since observed an analogous fact in the uraniferous zircons. At the conclusion of an investigation on the relations between absorption and dispersion, Dr. Kundt advanced the idea that in bi-refractive dichroic substances the absorption-bands of that of the two rays which has the greatest dispersion ought to be in the spectrum, nearer the red than for the other ray. Observation does not entirely agree with these views, which, as far as crystals are concerned, are not based upon direct experiment. The natural crystals in which absorption-bands have been recognised are parisite, monazite, various apatites, scheelite, and various uraniferous zircons. To this list may be added leucophane, melinophane, and the bacillary strontianite from Scotland in which the author has detected didymium. The absorption-spectra of these latter substances in natural light are composed of very fine bands, variously grouped, corresponding to the following wave-lengths:—

Scotch strontianite — 588, 584·5, 580·7, 577·5, 573·5, 570·3, 567.

Leucophane — 599, 593, 589·2, 585·5, 582, 578·2, 573·5, 528.

If we fuse leucophane the group of fine bands is replaced by diffused bands.

If we study the various crystals above-mentioned in polarised light we see the absorption-spectra change with the direction of the crystal.

Let us examine at first the phenomena presented by uniaxial birefringent crystals. We may mention as type the spectra of scheelite in which M. Cossa had detected didymium. The mean wave-lengths of the bands of the absorption-spectra are the following:—

Ordinary ray — 593 (trace), 588·5 (trace), 585 (strong trace), 579 (trace), 573·5 (strong trace).

Extraordinary ray—596, 593, 588·5, 586, 585, 579, 578, 573·5.

The other crystals give results of the same order.

We deduce from observations made in different directions that in uniaxial crystals the absorption-spectrum observed in any direction whatever is formed by the

superposition of two series of bands corresponding each to each of the principal directions of elasticity of the crystal.

The spectrum of the ordinary ray gives one of these series of bands which constitute the ordinary spectrum. For the extraordinary ray the bands displace each other only when the index varies with the direction of the ray, but the spectrum is formed by the superposition, in varying intensity, of the two series of bands just mentioned. In order to isolate completely the extraordinary spectrum the author is having crystals cut in suitable directions. In the direction of the axis the two spectra appear superposed, and only vary in intensity when the azimuth of the plane of polarisation of the light is varied.

In biaxial crystals the phenomena appear more complicated, and we may foresee the existence of three absorption spectra corresponding to the three axes of elasticity.

We may expect to find analogous variations in the phenomena of phosphorescence presented by crystals. Among phosphorescent crystals, where the author has recognised changes in the absorption-spectra, may be mentioned the salts of uranyle and in particular the double potassium-uranyle chloride, the very remarkable variations of which will be shown in a future memoir. Experiment has shown that in polarised light the phosphorescence-spectra of crystals do not appear to present any appreciable change and seem the same as in natural light. If there are several phosphorescence-spectra corresponding to the principal directions of the elasticity of crystals, as it is probable, it has not been possible to separate them, because the vibrations emitted by phosphorescence are not capable of polarisation.

The facts expounded in this note give the explanation of the following phenomenon:—

When a body absorbs or emits vibrations which seem as if they ought to be harmonic, these are affected by a perturbation which tends to approximate the absorption or emission bands in proportion as they are more refrangible. In fact for the same body, the index of refraction varying regularly by the fact of dispersion, each band must be displaced from the theoretical position which it should occupy and be removed so much the more towards the red as the index of refraction is greater. The successive bands must then tend to draw more closely together from the most refrangible side as observation shows. It is possible that a cause of the same order intervenes to determine the successive positions of the emission-rays of incandescent vapours.—*Comptes Rendus* (vol. cii., p. 106.)

CONTROL ANALYSES AND LIMITS OF RECOVERY IN CHEMICAL SEPARATIONS.*

By ALBERT B. PRESCOTT.

EVERY day chemical determinations are made by methods the shortages of which are unknown. Results are checked against other results in parallel operations; processes are compared with other processes as to highest obtainable results; the operator does the best he can, but has no factor of correction for inevitable deficiency. Certain operations in constant demand, in the service of industry and in pure science, such as the estimation of phosphorus in irons and the estimation of morphine in opiums, are rated by comparing results with each other, rather than measured by any standard of real truth. In many of these operations full control analyses are difficult to devise. In general, it may be said, trustworthy control operations are possible just to the extent that the material under analysis is capable of synthesis by the chemist. It must be his aim to make the artificial material identical with the original material in the following particulars:—

(1.) All the chemical constituents of the one should be present in the other in like proportion. (2.) The constituent to be estimated, as added in known quantity in the artificial material, should have the same physical condition as well as "chemical purity" that it bears in its quantity obtained from the original material. (3.) The constituents to be separated should in each case hold the same relations of adhesion. Adhesion is in general resistance to separations, holding back the "traces" that lie between our results and complete work.

The control analyses reported in this paper are such as have been resorted to at different times to test methods wanted for investigations immediately in hand, and therefore they have not the unity of design that might characterise a series of trials wholly devoted to the measurement of methods.

I. *Recovery of Strychnine from Bread and from Meat.**

Qualitative Limits:—

Limit of strychnine (sulphate) for "good" colour test, from a series of seven graded trials ..	0·0000025 gramme.
1. Recovering from 5 grms. bread, same limit, from a series of six graded trials	0·0001 ,,
Strychnine not recovered from 5 grms. of bread	0·0000975 ,,
Limit of recovery for 1 part of bread	0·0000195 strychnine.
Limit of recovery for 1 part of strychnine..	51282 bread.
2. Recovering from 5 grms. meat, same limit, from a series of seven graded trials	0·00016 gramme.
Strychnine not recovered from 5 grms. of meat	0·0001575 ,,
Limit of recovery for 1 part of meat	0·0000325 strychnine.
Limit of recovery for 1 part of strychnine..	30769 meat.
3. Recovering from 50 grms. meat, same limit, from a series of three graded trials	0·0004 gramme.
Strychnine not recovered from 50 grms. of meat	0·0003975 ,,
Limit of recovery for 1 part of meat	0·00000795 strychnine.
Limit of recovery for 1 part of strychnine..	125786 meat.

The strychnine was taken in solutions of known strength of the sulphate; the mixture with bread and meat was made by twenty-four hours' maceration; the separation was accomplished by a uniform method including treatment with alcohol, repeated on the residue, followed by repeated washing of the acidulated water solution with chloroform, and thorough washing of the same solution, after making it alkaline, with portions of the chloroform. The qualitative test was applied to the dry residue by a drop of sulphuric acid and a just visible fragment of dichromate.

The twenty-four hours' maceration is designed to effect a degree of adhesion, only approaching that usual in the material under analysis for poison. In comparing the results of group 2 with those of group 3 of tests, it is remarkable that by working with quantities ten times larger the ratio of recovery is made four times better. This indicates too great a degree of waste resulting from the manipulation, and implies that, especially in small operations, greater care should be taken in execution of every detail.

* Read at the Ann Arbor meeting of the American Association for the Advancement of Science, August 27th, 1885.

* These experiments make a part of an investigation, including trials of recovery from portions of the body after administration to animals, made by G. A. Kirchmaier, under the advice of the writer, and communicated in *Contributions from the Chemical Laboratory of the Univ. of Mich.*, ii., Ann Arbor, 1885.

II. *Recovery of Morphine from Bread and from Animal Tissues.*

Qualitative Limits* :—

Limit of morphine (sulphate) for good colour test	0·00005 gramme.
1. Recovery from 64 grms. bread, same limit, from a series of four graded trials	0·0004 ,,
Morphine not recovered from 64 grms. of bread	0·00035 ,,
Limit of recovery for 1 part of bread	0·0000054 morphine.
Limit of recovery for 1 part of morphine	185185 bread.
2. Recovery from 64 grms. membranous tissue, same limit, series of four trials..	0·0005 gramme.
Morphine not recovered from 64 grms. of tissues	0·00045 ,,
Limit of recovery for 1 part of tissues	0·000007 morphine.
Limit of recovery for 1 part of morphine	142857 tissues.
3. Recovery from 64 grms. liver same limit, from a series of four trials	0·0005 gramme.
Limits as in 2.	

Quantitative Limits :—

4. Recovery from 128 grms. tissue (membranous) by Meyer's solution, (1), 0·1 grm.	loses 0·01
(2), 0·05 grm.	,, 0·003
With 128 grms. of tissue, average loss of morphine	0·0065
Average loss of morphine for 1 part of tissue	0·000051
Average quantity of tissue for loss of 1 of morphine	19608
5. Recovery from 128 grms. liver, by Meyer's solution,—	
(1), 0·1 grm. ..	loses 0·0036
(2), 0·05 grm...	,, 0·02
With 128 grms. of liver, average loss of morphine	0·0118
Average loss of morphine for 1 part liver	0·000092
Average quantity liver for loss of 1 of morphine	10870

The morphine was taken in solution of the sulphate, o known strength; the mixture of morphine with bread, and with tissues, was made in the finely divided material, without digesting any time; and the separation was done by a constant method, as follows:—The material was extracted with alcohol acidulated with sulphuric acid; the filtrate was neutralised and evaporated to a syrup, then diluted with acidulated water and filtered and washed; the filtrate was concentrated and then washed with amyl alcohol. The remaining washed (aqueous) solution was made slightly alkaline by adding ammonia, and extracted with amyl alcohol, by shaking out with repeated portions. The amyl alcohol solution was washed with a little water and evaporated to dryness. For qualitative test the residue was moistened with sulphuric acid, and then drawn across with a sharp glass rod wet with nitric acid of sp. gr. 1·42. In the quantitative work the residue was taken up in water acidulated with sulphuric acid, and the solution titrated with Meyer's solution of potassium mercuric iodide.

The large waste of morphine in recovery shown by quantitative estimation accords with frequent experience of the instability of the alkaloid, and with the unsatisfactory results of estimations by Meyer's volumetric solution. On the other hand, the very small waste in the recovery shown by the qualitative results is at first surprising. Though the qualitative test itself was found to require twenty times as much alkaloid as sufficed for identification of strychnine, still it appeared that, in an operation only one-third larger, the recovery of morphine was made even more (one-seventh more) nearly complete than the recovery of strychnine. Had the morphine solution been macerated with the tissues twenty-four hours, as was done with the strychnine, the results might have compared very differently. But it is quite in accord with the results here quoted that morphine, though elusive from its instability, may interpose to separations less resistance of adhesion than does the more stable alkaloid strychnine.

III. *Recovery of Arsenic from Liver.**

Quantitative Limits. In comparison of three modes of separation :—

1. By corrosion with chlorate and hydrochloric acid, then precipitating as a sulphide.

	Per cent of liver.
(1.) In 62 gm. liver, 0·00127 As_2O_3 loses	0·00054—0·00087
(2.) ,, 0·00127 ,,	0·00059—0·00095
(3.) ,, 0·00127 ,,	0·00054—0·00085

For 1 part liver, average loss of As_2O_3—0·0000089.
Parts of liver, average for loss of 1 part As_2O_3—112360.

2. By distillation as arsenious chloride.

	Per cent of liver.
(1.) In 62 gm. liver, 0·00127 As_2O_3 loses	0·00056—0·00090
(2.) ,, 0·00127 ,,	0·00057—0·00092
(3.) ,, 0·00127 ,,	0·00059—0·00095

For 1 part liver, average loss of As_2O_3—0·0000092.
Parts of liver, average for loss of 1 part As_2O_3—108695.

3. By corrosion with sulphuric and nitric acids, not precipitating as sulphide.

	Per cent of liver.
(1.) In 62 gm. liver, 0·00127 As_2O_3 loses	0·00032—0·00052
(2.) ,, 0·00127 ,,	0·00034—0·00055
(3.) ,, 0·00127 ,,	0·00033—0·00053

For 1 part liver, average loss of As_2O_3—0·0000053.
Parts of liver, average for loss of 1 part As_2O_3—188698.

The arsenic was taken in a hydrochloric acid solution of arsenious acid, of known strength. After separation the arsenic was in each case estimated by weight of the "mirror" of elemental arsenic, reduced from arsine.

The separation of arsenic is, by either of these methods, entirely satisfactory. It appears that the precipitation as sulphide involves a loss, though very slight, that reduces the efficiency of the older method wherein this precipitation is employed. The qualitative limit of identification is nearly the same for arsenic that it is for strychnine, but the quantitative determination is very close for arsenic and not at all close for strychnine.

(To be continued).

* These experiments were made under the author's direction, by S. G. Steiner, and were in preparation for experiments made in recovering morphine administered to animals.

* These experiments were made, under the author's observation, by Mr. H. J. Holthoefer, in 1883, with the purpose of comparing the efficiency of three rival methods of separation, and the results were published in *Contributions from the Chemical Laboratory of the Univ of Mich.*, ii., p. 87.

ANALYSES OF SOME IRON ORES.

By J. CUTHBERT WELCH.

(Concluded from page 67).

III. *Göthite.*

Formula = $Fe_2O_3.H_2O$.

This requires—

Fe_2O_3	89·89
H_2O	10·11
	100·00

1. From St. Gotthard, Switzerland. Colour blackish brown. Streak dark brownish yellow. Adamantine lustre. Very brittle, but hard. Its specific gravity = 4·223. Metallic iron = 60·299 per cent.

Data.

Iron—
0·5 grm. required 30·15 c.c. potassium bichromate.
Combined water—
5 grms. gave 0·5923 grm. combined water.
Alumina—
5 grms. gave 0·0163 grm. alumina.
Silica—
5 grms. gave 0·0260 grm. silica.
Copper—
1·372 grms. gave 0·0098 grm. copper subsulphide.
Lime—
5 grms. gave 0·0255 grm. calcium sulphate.
Phosphorus—
4 grms. gave 0·0020 grm. magnesium pyrophosphate.

Percentage.

Fe_2O_3	86·142
H_2O (combined) ..	11·846
Al_2O_3..	0·326
SiO_2	0·520
CuO	0·714
CaO	0·210
P_2O_5	0·032
	99·790

This gives—

Fe_2O_3	87·911
H_2O	12·089
	100·000

2. A reddish brown specimen from Tincroft, Cornwall. It was partially encrusted by small tourmaline crystals, of a fine black colour, the largest being ¼ inch in length. Reniform. Streak yellowish brown. Not very hard, although fairly compact. Two determinations of its specific gravity gave 4·302 and 4·365; mean = 4·324. Metallic iron = 60·320 per cent.

Data.

Iron—
0·25 grm. required 15·08 c.c. potassium bichromate.
Combined water—
5 grms. gave 0·5707 grm. combined water.
Alumina—
5 grms. gave 0·0380 grm. alumina.
Silica—
5 grms. gave 0·0408 grm. silica.
Lime—
5 grms. gave 0·0087 grm. calcium sulphate.
Magnesia—
5 grms. gave 0·0022 grm. magnesium pyrophosphate.
Manganese—
2 grms. gave 0·0073 grm. trimanganic tetroxide.
Arsenic—
4 grms. gave 0·0172 grm. magnesium pyroarsenate.

Percentage.

Fe_2O_3	86·172
H_2O (combined) ..	11·414
Al_2O_3..	0·760
SiO_2	0·816
MgO	0·016
CaO	0·072
MnO	0·339
As	0·208
	99·865

This gives—

Fe_2O_3	88·304
H_2O	11·696
	100·000

The preceding analyses were all made upon a sample as free from gangue as possible, in order to obtain a good notion of the composition of the ores themselves. The results obtained prove, in my opinion, that those substances present foreign to the chemically pure ore are actually in combination in the ore itself, and that their presence is not due to admixed portions of the gangue.

The potassium bichromate solution used was such that 1 c.c. = 0·01 Fe.

The analyses of all the specimens were made upon the original hygroscopic ore, and the results given under the column headed "Dried at 100° C." are calculated from these percentages previously obtained, the hygroscopic water having been determined at this temperature.

CONTRIBUTIONS TO THE KNOWLEDGE OF SAMARIUM.*

By P. T. CLEVE.

(Continued from p. 69).

Selenates of Samarium.

I. $Sm_2(SeO_4)_3 + 8H_2O$. This salt crystallises from a very concentrated solution on evaporating over oil of vitriol at 18°, in small sulphur-yellow crystals. The selenate is very soluble; it loses scarcely any water at 100°, but it becomes anhydrous at 280°.

1. 0·9881 grm. lost on careful heating over open fire 0·1642 grm., and left on heating to a white heat 0·3951 grm. Sm_2O_3.

2. *a.* 0·6223 grm. decomposed with boiling hydrochloric acid and treated with sulphurous acid gave 0·1679 grm. Se. From the filtrate 0·2457 grm. Sm_2O_3 was thrown down with oxalic acid.

b. 0·8165 grm. lost by 280° 0·1330 grm. H_2O.

In per cent—

	I.	II.	Calculated.	
Sm_2O_3	39·99	39·48	348	39·86
SeO_3	—	43·37	381	43·64
H_2O	16·62	16·29	144	16·50
			873	100·00

The selenate of samarium does not give any compound with selenate of sodium. On spontaneous evaporation of the mixed solutions one gets crystals of selenate of samarium.

Sp. gr. of the crystallised salt—
1·3973 grm. crushed crystals, t° 13°, sp. gr. 3·326
1·2697 „ „ „ „ 3·329
Mean of both determinations, 3·327.
Molecular volume, 262·4.

II. $Sm_2(SeO_4)_3 + 12H_2O$. It crystallises at about 10° in yellow brilliant beautiful prisms which alter rapidly in the air.

0·4915 grm. lost by 100° 0·1204 grm. H_2O and by 230° 0·0850 grm. By ignition 0·3549 grm. Sm_2O_3 was obtained.

1·5643 grm. lost by 230° 0·3425 grm. H_2O.

In per cent—

Sm_2O_3	37·70	348	36·83

Molecular volume, 119·3.

Sulphite of Samarium, $Sm_2(SO_3)_3 + 3H_2O$.

The oxide of samarium dissolves easily in a saturated aqueous solution of sulphurous acid. If the clear solution be heated on a water-bath a white amorphous powder is thrown down. For analysis the salt was pressed between filter-paper.

0·4105 grm. lost by 100 to 110° 0·0159 grm. H_2O and gave 0·4024 grm. $Sm_2(SO_4)_3$.

0·4110 grm. lost 0·0142 grm. and gave 0·4047 grm. $Sm_2(SO_4)_3$.

In per cent—

			Calculated.	
Sm_2O_3	58·02	58·28	348	58·59
SO_2	—	—	192	—
H_2O	3·87	3·46	54	9·03
			594	

The salt loses at 100° $1H_2O$.

Selenites of Samarium.

1. *Basic Salt.*—On adding an excess of neutral selenite of sodium to the sulphate of samarium a voluminous and gelatinous precipitate is thrown down. This precipitate was dried at 100° and analysed.

0·9005 grm. dissolved in HCl and precipitated with SO_2 gave 0·2735 grm. Se. The Sm_2O_3 obtained from the filtrate by precipitation as oxalate amounted to 0·462 grm.

In per cent—

Sm_2O_3	51·30
SeO_2	42·67
H_2O	(6·03)
	100·00

The ratio between Sm_2O_3, SeO_2, and H_2O is 1 : 2·6 : 2·3 or 3 : 8 : 7.

The precipitate consisted of a basic salt the composition of which, if it be regarded as a chemical compound, may be expressed by the formula—

$3Sm_2O_3,8SeO_2 + 7H_2O$.

Sm_2O_3	1044	50·73
SeO_2	888	43·15
H_2O	126	6·12
	2058	100·00

It seems most probable that it is only a mixture o basic salts with the neutral selenite. According to M Nilson the selenite of didymium, prepared in the same way as this salt, has the composition—

$3Di_2O_3,8SeO+28H_2O$.

2. *Acid Selenite*, $Sm_2O_3,4SeO_2 + 5H_2O$.— This compound was thrown down by addition of selenious acid to the solution of the acetate, as a bulky precipitate, which was very soon transformed into microscopic needles.

0·8312 grm. lost at 110° 0·0523 grm. H_2O, and gave, treated in the same manner as the salt last described, 0·2935 grm. Se and 0·3233 grm. Sm_2O_3.

0·8910 grm. gave 0·0560 grm. H_2O, 0·3175 grm. Se and 0·3465 grm. Sm_2O_3.

In per cent—

			Calculated.	
Sm_2O_3	38·90	38·89	348	39·46
SeO_2	49·61	50·07	444	50·34
H_2O..	6·29	6·28	$3H_2O$ 54	6·12
			$2H_2O$ 36	—

Carbonate of Samarium,

$Sm_2(CO_3)_3 + 3H_2O$ (or $2H_2O$ dried at 100°).

The gelatinous precipitate which the nitrate of samarium gives with ammonia liquor was, after washing with cold water, suspended in water and treated with carbonic acid gas. After some time a whitish powder consisting of aggregates of microscopic needles insoluble in water was obtained. The salt pressed between filter-paper lost at 100° 4·70 per cent (1 mol. H_2O = 3·37 per cent).

0·401 grm. dried at 100° gave by ignition 0·2673 grm. Sm_2O_3.

0·2852 grm. was mixed with bichromate of potash and heated in a combustion-tube. The water was accidentally lost, but the carbonic acid, absorbed by potash ley, weighed 0·0738 grm.

0·3269 grm. gave 0·2186 grm. Sm_2O_3.

In per cent—

			Calculated.	
Sm_2O_3	66·66	—	66·87	348	67·44
CO_2	—	25·88	—	132	25·58
H_2O	—	—	—	36	—
				516	

Carbonate of Samarium and Potassium,
$SmK2CO_2 + 6H_2O$.

A solution of the nitrate of samarium gives, on adding bicarbonate of potassium, a voluminous gelatinous precipitate, which, in presence of an excess of the bicarbonate, is after a time changed into thin glittering crystals. The salt, after pressing between filter-paper, was analysed :—

I. 0·7635 grm. lost by 100° 0·1742 grm. H_2O. The residue was dissolved in hydrochloric acid and precipitated with ammonia. The solution of the hydrate, thus thrown down, was precipitated with oxalic acid and the oxalate ignited. The filtrate from the hydrate was evaporated, the residue carefully ignited and weighed as KCl. 0·3204 grm. Sm_2O_3 and 0·132 grm. KCl were thus obtained.

II. 0·4701 grm. lost at 125° 0·1146 grm. H_2O and gave 0·1964 grm. Sm_2O_3 and 0·0844 grm. KCl.

In per cent—

PROCEEDINGS OF SOCIETIES.

CHEMICAL SOCIETY.

Thursday, February 4th, 1886.

Dr. Hugo Müller, F.R.S., President, in the Chair.

Messrs. Robert G. Cristopher, George E. R. Ellis, and E. E. H. Thorne were formally admitted Fellows of the Society.

Certificates were read for the first time in favour of Messrs. James Henry Allan, 6, St. Chrysostom Street, Liverpool ; Leopold Mandeville Deane, 52, Elswick Road, Newcastle-on-Tyne ; Preo Loll Day, 4, Bradon Street, Calcutta ; James Arthur Formoy, 12, Railway Approach, London Bridge ; Edward Willmore, 69, Lichfield Road, Bow, London, E.

The following note was read :—

12. "*The Chemical Formula for Wool Keratine.*" By Edmund J. Mills, D.Sc., F.R.S.

In the last number of the *Proceedings* Mr. Whitely points out, in Abstract No. 10, that Mills and Takamine gave (*Chem. Soc. Trans.*, 1883, 142) a necessarily wrong formula for wool, their calculation having been based on data in Gmelin's *Handbook*, xviii., 351, where H is misprinted for N. Mr. Whitely then deduces from the corrected results the formula $C_{41}H_{71}N_{12}SO_{14}$.

I wish to point out in the first place that, in the paper by myself and Takamine, the formula of wool was merely an incident, the main object being to give an account of the absorption of weak reagents, by cotton, silk, and wool. In the second place, I myself noticed the misprint in Gmelin's *Handbook* as long ago as last May (*Journ. Soc. Chem. Ind.*, 1885, 328), and calculated out for wool the corrected formula $C_{39}H_{65}N_{11}SO_{13}$, which agrees well with the results of its destructive distillation.

A Lecture was delivered on—

13. "*Methods of Bacteriological Research from a Biologist's Point of View.*" By Dr. Klein, F.R.S.

The object of the Lecture was to bring before the Chemical Society the methods used at present by pathologists in the investigations of micro-organisms associated with disease. These methods, thanks to the investigations of Koch, are greatly in advance of those hitherto employed by chemists in the investigation of the activity of bacteria. The enormous amount of work that has been done by chemists since the memorable investigations of Pasteur on fermentation and putrefaction, if viewed in the light of the modern bacteriological methods) is in a great measure unsatisfactory and imperfect, more so than will be conceded by chemists. This unsatisfactory state is chiefly due to the imperfect methods employed. Specific chemical action is ascribed to certain organisms, because these were found present in the substances examined, no regard being paid as to whether these organisms were alone active or whether they were only concomitant and dependent on the activity of others.

Numbers of instances can be adduced to prove this : amongst them may be mentioned the assertions that alcoholic fermentation is produced by *Mucor racemosus*, and also by a bacillus besides saccharomyces ; that the ammoniacal fermentation of urine is due to a bacillus ; that the lactic acid fermentation is due to a micrococcus and also to a bacillus.

To determine whether a definite chemical process is produced by a definite organism, and which, it is necessary to prove—(1) that the substances to be acted upon are at the outset free of any accidental organisms ; (2) that the particular organism to which the definite chemical activity is ascribed is the only one concerned in this process.

The methods used must fulfil these elementary conditions, that is to say :—(1) the materials used must be sterile at the outset, and protected from accidental contamination ; (2) the specific organism must be obtained in pure cultivations, and this purified organism must be capable of producing the specific chemical change.

Viewed in this light few of the assertions hitherto made bear criticism. As one of the most striking instances it may be mentioned that, notwithstanding the enormous amount of knowledge gained by chemical research into the changes of proteid bodies during putrefaction, there is no reliable answer yet given to the questions—Which organism or organisms are concerned in this complex process ? Which part of the process is due to which organism ? Is the analytical process by which proteids are carried down to relatively simple nitrogenous principles done by one or more organisms and by which ? Is the production of the alkaloids known as ptomaines due to the same organism or organisms which started the process of putrefaction ?

Another equally important series of investigations refers to the process of nitrification ; here also no definite answer can be given. So also the chemical changes due to the growth of moulds are waiting for investigation.

When chemical research begins to adopt such methods as are employed by pathologists, but not till then, its results will be unequivocal.

The methods used for sterilising materials, for studying and recognising the morphological characters of organisms, for obtaining pure cultivations, and for inoculating nutritive materials with them were then minutely described.

Discussion.

Prof. Frankland, after dwelling on the importance of intercourse between biologists and chemists, said that he

must plead guilty to the charge of having neglected precautions now known to be necessary when making his experiments on the fermentation of urine; he could, however, urge that there were extenuating circumstances, as the experiments were carried out ten years ago when the necessity of such precautions being taken was not yet realised. He did not contend that the vibrios observed by him were the sole agents, but they were for days apparently almost exclusively present. It appeared to him that a point of primary importance brought forward by Dr. Klein was the fact that certain pathogenic organisms only develop at a relatively high temperature. It was probable that in the future the study of the chemical effects of organisms would be of greater service even than that of morphological characters as a means of differentiating various organisms. As regards *Mucor racemosus*, the statements in his paper were derived from the published researches of Dr. James Bell.

Mr. Warington described the conditions under which his experiments on nitrification were made. The solutions contained a very small proportion of nutritive matter, and the action was extremely slow: after three or four days a slight turbidity was observed, but nitrification did not set in until after about one month. He had made four or five successive cultivations, more being impossible by reason of the slowness of the action.

Dr. Percy Frankland said that, as Dr. Klein had properly stated, he had not asserted that the number of organisms found present on his plates was the number of organisms present in the water examined. His experiments were made not so much with the object of discovering pathogenic organisms, but in order to study what took place in the ordinary processes of water purification. Of all known media he thought that none was so universally applicable to the cultivation of micro-organisms as gelatin peptone. The danger from air contamination was perhaps overrated. To illustrate how very slight is the contamination, he had recently exhibited a series of 12 plates put up with sterilised water, and of these only one had a growth upon it. He had recently made experiments with air confirming Hesse's observations, having found only 10 organisms in 20 litres—this, however, being in snowy weather. He had also made experiments on the number of organisms which fell upon a plate of gelatin such as was employed when working according to Koch's directions, and had found about two per minute. He thought that the experiments on fermentative action hitherto made were worthless from neglect of the precaution to employ pure cultivations.

Dr. Armstrong said that it undoubtedly was most important that the necessity of using pure cultivations should be impressed upon the chemist, but the work hitherto done in this field, far from being worthless as Dr. Percy Frankland had stated, was absolutely of almost as great value as if pure organisms had been dealt with. In most cases of putrefactive change the products were very numerous, their separation and identification was excessively difficult, and in not a few instances they were new to the chemist. Until the chemical methods of examining such products had been perfected, it was useless to incur the great labour involved in obtaining pure cultivations on a sufficient scale. This had been clearly recognised by most of the recent workers on the subject.

Mr. Ekin inquired if the organisms present in water might not play the part of useful scavengers? Evidence of this would, he believed, ere long be forthcoming.

Dr. Thudichum observed that the biologist working with impure ferments could be compared to the chemist employing impure reagents. The results of the life of microzymes were to a large extent chemical, as was known from ordinary fermentation; this was equally true of ferments which caused diseases. Thus in splenic fever, which he had investigated on a farm in Leicestershire, where it was endemic, he had found all hæmochrom transformed into methæmoglobin, and the spleen filled with crystals of albuminous decomposition products. In cholera a poison was formed by the bacilli which affected the muscles, and by fluidifying the colloids caused sinking of temperature, or the algid stage. In all diseases, however, the presence of bacilli, as in all fermentations, led to the evolution of heat, which with its attendant symptoms was termed fever. Fever heat had two sources; one was increased combustion, another the liberation of latent or atomic heat which was peculiar to the bioplasm. Now this liberation of atomic heat under the influence of the bacilli or their products led to a remarkable consequence, namely, a contraction of the atomic volume of the bioplasm; and when the tissues had attained the smallest atomic volume compatible with their function, bacilli could no longer live or thrive in them; the contracted bioplasm had attained to the state of immunity from the bacilli and their products. This state of immunity was attained not only through the action of specific bacilli, but also of their modification called vaccines. He agreed with Dr. Armstrong in two particulars concerning the chemical treatment of questions connected with bacilli. The fermentations might be studied with impure ferments, provided the processes were on a large scale, and a recognisable particular ferment prevailed. All possible decomposition products might be investigated first, and then the results of fermentations with pure ferments, or pure cultivations of bacilli, would be much easier of discovery. In particular, as a pathologist, he was quite certain that investigations of a chemical kind on the changes effected by microzymes in the composition of animal tissues and fluids would not be adequately successful before the entire chemistry of these substances and all their decomposition products was completely known.

The President asked Dr. Klein whether the statement had been confirmed that *B. amylobacter* loses its specific character by cultivation in oxygenated media and when its spores are heated.

Dr. Klein, in reply, said that he agreed with Prof. Frankland that the chemical aspect of the problem was the important one to study in the future: at present it was entirely unknown how the diseases associated with the presence of anthrax or the tubical bacillus, for example, were produced. Light had in most cases a deleterious influence on the growth of bacteria; but some live only in light, and it had been stated that the so-called *Bacterium photometricum* lived only when exposed to a definite part of the spectrum. Dr. Percy Frankland had somewhat misunderstood him: he certainly thought that the gelatin method was the most useful one to employ in determining the number of bacteria in two given specimens of water, but he did not agree that gelatin-peptone was the most universally applicable medium; several organisms would grow in agar-agar, but not in gelatin, and blood serum was certainly better—indeed he did not know any organism which would not grow in it. As regards the struggle between organisms, there were cases known of non-pathogenic causing the destruction of pathogenic organisms present along with them. With reference to the employment of pure cultivations, what he had desired to point out was that the statments that certain chemical changes were brought about by certain organisms were based upon insufficient evidence—he wanted to have them placed beyond question by the use of pure cultivations. Changes such as were referred to by the President certainly took place; thus Pasteur had found it possible to alter the functions of the *Anthrax bacillus*.

At the next meeting on February 18, there will be a Ballot for the Election of Fellows, and the following papers will be read:—

"On the Constitution of Undecylenic Acid as indicated by its Magnetic Rotation; and on the Magnetic Rotation, &c., of Allylacetic Acids and Ethylic Diallylmalon." By W. H. Perkin, F.R.S.

"On Reactions supposed to yield Nitrosyl Chloride." By W. Collingwood Williams, B.Sc.

"On the Condition in which Silicon exists in Cast Iron." By A. E. Jordan and T. Turner.

ROYAL INSTITUTION OF GREAT BRITAIN.

General Monthly Meeting, Monday, February 1, 1886.

WARREN DE LA RUE, M.A., D.C.L., F.R.S., Manager and Vice-President, in the Chair.

THE following were elected Members:—William Anderson, M. Inst. C.E., Henry Arthur Blyth, James Blyth, James Crowdy, Brownlow D. Knox, Mrs. Shepherd, W. F. R. Weldon, M.A.

Sixteen Candidates for Membership were proposed for election.

The Presents received since the last Meeting were laid on the table, and the thanks of the Members returned for the same.

NOTICES OF BOOKS.

A Practical Introduction to Chemistry: intended to give a Practical Acquaintance with the Elementary Facts and Principles of Chemistry. By W. A. SHENSTONE, Lecturer on Chemistry in Clifton College. London: Rivingtons.

WE have from time to time had occasion to express our regret at the multiplication of chemical annuals not evincing any special *raison d'être*. The little work before us has, however, a very definite aim, and a method which appears to us thoroughly scientific. The very first sentence in the author's Introduction is so significant that, were we a Sultan of the "Arabian Nights," we would have it written up in letters of gold over the door of every college and school in our realm:—"There can be no doubt," he writes, "that Science is of special educational value chiefly in proportion as it leads the students to observe accurately, to record their observations correctly, and to think for themselves." That a teacher who carries out this view will train up his pupils to *know* cannot be questioned. Whether they will *pass* better than, or as well as, others taught in a less rational manner is another affair. The arts of accurate observation and of drawing correct conclusions from observations made and recorded do not seem capable of being estimated by examiners.

Mr. Shenstone does not begin operations with giving a brief account of the elements *seriatim*, to be received as a creed and committed to memory. His first chapter deals with "Burning." But he writes—"In this book you will not be told straight off what is known on this and other subjects. Instead of that you will be instructed to make certain experiments, and you must try and find out for yourself what the experiments teach you about the subjects. If you do this earnestly you will gradually gain the power of making discoveries for yourself, which is much better than being told things." Most true: this is the only way in which chemistry, or indeed any science, can be rationally taught,—the only method by which discoverers and inventors can be trained up. Why do we, as a nation, so obstinately reject it?

We feel convinced that the Clifton College will give practical proof of the soundness of the author's views if the "tyrant Examinationalism" do not interfere.

Chemical Student's Manual for the Lecture-Room and Laboratory: embracing Non-metals, the Analysis of Simple Salts, Historical and much other Useful Memoranda. By H. L. BUCKERIDGE, F.C.S., A.A. (Oxon), &c. London: Murby.

THE author tells us that his aim—modest, though not the less difficult—is to present the student with a book of notes, comprehensive, systematic, of easy reference, and therefore "of the utmost possible service in the laboratory, the lecture-room, or in the seclusion of private study." The Preface ends with the *banal* announcement that the course laid down is such as to prepare the student for—&c., &c.

The "Chemical Notabilia" consist of elementary definitions, statements of certain laws, remarks on notation, instances of different kinds of formulæ, tables of weights and measures, the determination of vapour-densities, dates of discoveries, typical problems, a glossary, and a string of questions. The glossary gives the explanation of only some twenty terms, some of them, such as "inflammable" and "malleable," of such common use as to be universally understood.

It might be difficult to find in this volume anything to which we might fairly object; but it would be also difficult to find any marked advantage which it possesses as compared with other elementary chemical treatises.

Chemiker-Kalendar, 1886. *Ein Hülfsbuch fur Chemiker, Physiker, Mineralogen, Industrielle, Pharmaceuten, Hüttenmänner, u.s.w.* (Chemist's Amanac, 1886. An Aid-Book for Chemists, Physicists, Mineralogists, Manufacturers, Pharmacists, Metallurgists, &c.) By Dr. RUDOLF BIEDERMANN. Seventh Year, 1886. Berlin: J. Springer.

THIS calender continues its career of usefulness. In the preliminary almanac department we find given the meetings of the principal scientific and technological societies of Berlin, followed by a brief table of frequently required atomic weights and their multiples. Amongst the principal additions in the issue for the current year particular attention must be called to the chapter on thermochemistry, with the tables on formation-heats. In the chapter on light new tables of wave-lengths and on the exponents of refraction have been added. The section on electricity has been enlarged in view of the increasing development of electrolytic analysis and of metallurgy. There are also tables of elasticity and hardness, which of course concern the chemist much less than the engineer. Most of this additional matter is contained in an appendix printed as a small separate volume. An interesting feature is a list of dates of remarkable discoveries and inventions, not confined exclusively to chemistry, and of other important events in the history of science. Here we must point out an error. We read "Foundation of the Royal Academy in London, 1662." It should be "Royal Society," the Royal Academy being a totally different body of much later origin, and not being concerned with scientific research, but with the fine arts. It may call up a smile or a sigh, according to the reader's point of view, to find the first establishment of the betose manufacture placed among the world's memorable events! In the diary department we find the anniversaries of the birth- and death-days of the eminent scientific men of all nations. By a clerical or typographic error we find the birth-place of Isaac Newton given as "Whoolstorpe." In spite of the great condensation necessary in compressing such a wonderful amount of useful matter into a strictly pocket-size there is no fear of injury to the eyes. The paper is of excellent quality, and the type, though necessarily small, is beautifully clear. The arrangement of the subject matter is also such that no space is wasted. The "Chemiker-Kalendar" may indeed be pronounced a model in its kind.

Chlorination of Carbides.—A. Colson and H. Gautier.—Phosphorus perchloride is a reagent which renders it possible to introduce a given quantity of chlorine into the hydrocarbon molecule. The chlorine liberated by the decomposition of the perchloride reacts at first upon the lateral chains before attacking the benzol nucleus.—*Bull. de la Soc. Chim. de Paris*, No. 1, 1886.

CORRESPONDENCE.

OXIDE OF IRON AND ALUMINA IN PHOSPHATES.

To the Editor of the Chemical News.

SIR,—By the publication of the method used by himself, (CHEM. NEWS, vol. liii., p. 51) Mr. Bernard Dyer has done much to secure the adoption of a uniform method for the estimation of iron and alumina in commercial phosphates.

If he and his brother analysts could be induced to publish their methods of estimating phosphoric acid in phosphates and manures, they would confer a boon upon manufacturers, works' chemists, and every one concerned.

There can be no doubt that the discrepancies complained of in oxide of iron and alumina determinations are in part caused by the use of different solvents. Hydrochloric acid, nitric acid, and *aqua regia* are indiscriminately used to effect solution of the phosphates, the iron and alumina found in solution being returned as "oxide of iron and alumina."

Such results are clearly misleading, and are of no practical value to the manufacturer, as the amount of iron and alumina present in a phosphate over and above that which is soluble in sulphuric acid is a matter of indifference to him.

Instead of seeking to show the amount of iron existing as oxide, phosphate, pyrites, ferrous silicate, &c., it would be much simpler to estimate the amount of iron and alumina which is soluble in the solvent actually employed in the manufacturing process, the result being stated as oxide of iron and alumina soluble in sulphuric acid. The results obtained in this way would have at least a practical value, which many of the present determinations do not possess.

The following table shows the results which I have obtained by dissolving the phosphates in sulphuric acid as suggested above, and also, for comparison, those obtained by dissolving in hydrochloric acid to which a little nitric acid has been added, the iron and alumina being precipitated and weighed as phosphates.

Name of phosphate.	Phosphates of iron and alumina in $HCl+HNO_3$ solution.	Phosphates of iron and alumina in H_2SO_4 solution.
1. Bull River	7·30	3·00
2. „	6·05	2·45
3. „	5·10	3·40
4. Port Royal	8·38	2·31
5. „	6·66	2·50
6. „	5·77	1·52
7. Oak Point	7·13	3·53
8. Bolton River ..	7·38	2·82
9. Sand, Carolina ..	10·68	7·15
10. Chisolm Rock ..	7·32	5·50
11. Spanish..	3·75	2·35
12. „	2·66	1·75
13. Canadian	6·75	2·85
14. „	5·75	3·15
15. „	4·47	1·95
16. Belgian..	26·00	20·60
17. „	17·85	14·00
18. „	3·05	1·52
19. „	1·95	1·20
20. Aruba	9·12	5·37

It will be seen from this table that some of the phosphates (Nos. 4 and 8, for instance) which show a comparatively large amount soluble in the *aqua regia* solution contain only a small amount soluble in sulphuric acid.

With regard to the method of estimating the iron and alumina, the following process, which contains nothing original, gives good results:—10 grms. of the sample are boiled with hydrochloric acid and evaporated to dryness with a little nitric acid. The residue is taken up with hydrochloric acid, filtered, and the filtrate made up to 500 c.c.

Three portions of 100 c.c. each are taken for analysis.

In the first the ferric oxide is estimated volumetrically.

The second and third are precipitated with ammonic acetate. The precipitates, after being washed on filters, are dissolved in hydrochloric acid, some sodic phosphate added to the solution, and the ferric and aluminic phosphates again precipitated with ammonic acetate. One of the precipitates is dissolved in nitric acid and the phosphoric acid estimated by means of molybdic acid. The other precipitate is ignited and weighed as total phosphoric acid, ferric oxide, and alumina.

The phosphoric acid and ferric oxide found being deducted from the total, the difference gives the alumina.

When it is desired to estimate the iron and alumina soluble in sulphuric acid it is advisable to dilute the solution largely before boiling to ensure complete decomposition of the phosphate.—I am, &c.,

WILLIAM W. MELLON.

Ouse Chemical Works, Howden, Yorks.
February 3, 1886.

CHEMICAL NOTICES FROM FOREIGN SOURCES.

NOTE.—All degrees of temperature are Centigrade unless otherwise expressed.

Biedermann's Central Blatt fur Agrikultur Chemie.
Vol. xiv., Part 10.

The Proportion of Oxygen in Atmospheric Air.—Prof. U. Kreusler.—The author, in view of the recent doubts as to the constant composition of the atmosphere, raised by Von Jolly and others, maintains—as the result of a series of 106 analyses—the correctness of the ordinary assumption of constancy within very narrow limits, so that the conflicting observations are not sufficiently guaranteed.

Magnetic Particles of the Atmosphere.—P. Bonizzi.—The author has examined very closely the magnetic particles of atmospheric dust, collected in the most different localities of Italy. He finds that in all kinds of dust, whether collected in the open air or in closed spaces, there are always present magnetic particles, differing in number and in size. These particles are not homogeneous, but differ in their mineralogical composition. In form they vary greatly, though the globular shape predominates. The dusts collected in exposed localities almost invariably contain spherical magnetic bodies, which are rarer or altogether wanting in the dust of closed localities.

The Pollution of the Emscher at Dortmund.—A. Müller.—The impurities of the Emscher, a small tributary of the Rhine, are traced to the influx of foul waters above Dortmund, the sewage of the town, the waste waters of breweries, and the drainage of the mines. The last-mentioned waters are poor in organic matter, but their high percentage of sulphates in contact with putrescent organic matter gives rise to a plentiful liberation of hydrogen sulphide, and renders them unfit for irrigation. Analyses made at different points of the stream prove that a process of self-purification takes place.

Purification of Impure and Foul Industrial Waste Waters of Irrigation.—J. König and C. Böhmer.—The authors find that treatment with lime still leaves much impurity in the water. Irrigation requires the largest possible surfaces and very permeable soil. They consider also that the mere removal of the suspended impurities is insufficient.

Joint Manurial Experiments in the Province of Hanover.—Prof. Drechsler.—The results of these experiments are given in the form of tables.

Changes in and Preservation of Farmyard Manure.—Dr. E. Heiden.—Superphosphate-gypsum (the composition of which is not stated, but which may be the "phosphatic gypsum" of the English trade) is found to retain ammonia rather better than kainite.

The Gastric Juice and the Histology of the Mucous Membrane of the Stomach of Swine.—Ellenberger and Hofmeister.—The gastric juice of swine contains the same ferments as that of other domestic animals. It dissolves albumenoids, converting them into peptone, propeptone, and syntonine; coagulates milk and splits up the fats, though only to a slight extent.

The Digestibility of Cotton-Seed Cake and Meal.—H. Weiske, B. Schulze, and E. Flechsig.—The nutritive value of cotton-seed cake is given as slightly higher than that of rape cake, with the additional advantage that cattle eat it with more relish.

Experiments on the Influence of the Ingestion of Free Acids upon the Digestive Process in the Herbivora, as well as upon the Metabolism of Nitrogen and Mineral Matters in their Bodies.—H. Weiske and others.—The authors consider that the digestive coefficients of acidified and of normal hay differ little. In animals fed with sulphuric hay, all the bones except the skull and those containing marrow were found about 2 per cent poorer in mineral matter than those of animals fed on normal hay.

The Growth and Increase of Crystals.—O. Kœppert.—The author has made a comparative examination of the size and number of crystals of calcium oxalate in the corresponding parts of young and old plants.

The Influence of "Topping" upon the Development and Productiveness of Plants.—E. Wollny.—Upon sunflowers the influence of topping varies according to the time when it is performed. All topped plants bloomed later than those not topped, and produced imperfect seeds. In the case of tobacco topping promotes the growth of leaves. In peas and beans the quantity both of straw and fruit is diminished. Maize is improved both in quantity and quality. In potatoes both the number and the weight of the tubers were reduced.

A Ferment in Plants which transforms Cellulose into Gum and Mucus.—Julius Wiesner.—The author has observed that gum-arabic contains a ferment which in the plant effects the conversion of cellulose into gum. This gum-ferment is of a diastatic character, but it is distinguished from other diastases by converting starch merely into gum, and not into reductive sugar. It even seems capable of annulling the action of ordinary diastase.

The Blackening of the Roots of Young Beet-Plants.—Prof. Kühn.—Injury is occasioned by the larvæ of *Atomaria linearis* and by certain species of *Julus*.

The Use of Copper Sulphate for Destroying Peronospora viticola.—A. Perrey.—From the *Comptes Rendus*.

On House Fungus.—Poleck.—This fungus, *Merulius lacrimans*, attacks chiefly timber felled in spring and summer. Its ash contains 75 per cent of potassium phosphate.

NOTES AND QUERIES.

*** Our Notes and Queries column was opened for the purpose of giving and obtaining information likely to be of use to our readers generally. We cannot undertake to let this column be the means of transmitting merely private information, or such trade notices as should legitimately come in the advertising columns.

Tartaric Acid.—As we deal in tartaric "matters" we should be very glad to know the statistics for England, import and export, of tartaric acid, cream of tartar, raw products (wine lees, tartar, &c.), and also, if possible, the consumption in England.—P. and E. Gasquy de B. E & Co., Marseilles.

MEETINGS FOR THE WEEK.

Monday, 15th.—London Institution, 5.
— Medical, 8.30.
— Society of Arts, 8. (Cantor Lectures). "Science Teaching," by Prof. F. Guthrie, F.R.S.
Tuesday, 16th.—Institution of Civil Engineers, 8.
— Pathological, 8.30.
— Royal Institution, 3. "The Unexhibited Portion of the Greek and Roman Sculptures in the British Museum," by C. T. Newton, C.B.
— Society of Arts, 8. "The Present State of the Colonial Possessions of Great Britain," by Dr. Robert J. Mann.
Wednesday, 17th.—Society of Arts, 8. "Some Points in Electrical Distribution," by Prof. George Forbes.
— Meteorological, 7.
Thursday, 18th.—Royal, 4.30.
— London Institution 7.
— Royal Institution, 3. "Metals as affected by Small Quantities of Impurity," by Prof. W. Chandler Roberts-Austen, F.R.S.
— Royal Society Club, 6.30.
— Chemical, 8. "Constitution of Crude Oleic Acid as indicated by its Magnetic Rotation; and on the Magnetic Rotation of Allylacetic Acid and Diallylmalonic Ether," by Dr. W. H. Perkin, F.R.S. "On Reactions supposed to Yield Nitryl Chloride," by W. Collingwood Williams, B.Sc. "On the Conditions in which Silicon Exists in Cast-iron," by A. E. Jordan and Thomas Turner.
Friday, 19th.—Royal Institution, 9. "The Wings of Birds," by Prof. W. H. Flower, F.R.S.
— Geological, 1. (Anniversary).
— Society of Arts, 8. "Historical and Recent Famines in India," by F. C. Danvers.
Saturday, 20th.—Royal Institution, 3. "The History of Volcanic Action in the British Isles," by Archibald Geikie LL.D., F.R.S.

SCIENCE AND ART DEPARTMENT OF THE COMMITTEE OF COUNCIL ON EDUCATION.

NORMAL SCHOOL OF SCIENCE AND ROYAL SCHOOL OF MINES, SOUTH KENSINGTON.

A Course of Fifty Lectures on ORGANIC CHEMISTRY will be delivered on Mondays, Wednesdays, and Fridays, at 10 a.m., by Dr. F. R. JAPP, F.R.S., commencing on February 15th.

The Course will treat of the various Vegetable Principles (Dyestuffs, Alkaloids, &c.), with the Mode of their Extraction; the Synthesis of some of these Principles; Compounds occurring in the Animal Organism; and the Artificial Organic Compounds of Scientific or Industrial Interest.

Stress will be laid on the theoretical bearings of the various compounds, and the methods employed in determining their constitution will be described

A detailed Syllabus of the Course may be obtained on application to the Registrar.

TO CHEMICAL MANUFACTURERS.

TO BE LET OR SOLD, a Modern Works, eligibly situated near Manchester, with or without a large Plot of Land, Freehold, on a small chief rent.—Apply, A. B., Chemical News Office, Boy Court, Ludgate Hill, London, E.C.

THE CHEMICAL NEWS.

NOTE ON THE

SOLUBILITY OF BARIUM SULPHATE IN HYDROBROMIC AND HYDRIODIC ACIDS.

By ARTHUR R. HASLAM.

While recently engaged in the preparation of hydrobromic acid by the process now given in the British Pharmacopœia, an attempt was made to precipitate the sulphuric acid contained in the crude liquor with barium carbonate previous to distilling off the acid: on filtering the mixture it was afterwards found that the filtrate still contained traces of barium sulphate in solution. I have not been able to find any reference to, or note of, this fact, and therefore I venture to record here the following experiments, with their results:—

Pure barium sulphate was obtained by precipitating pure barium chloride with a slight excess of sulphuric acid. The precipitate was washed four or five times by decantation, and then thrown on a filter, and further washed with distilled water until all trace of acid had disappeared; it was then dried in a hot-water oven. In these experiments water distilled three times was used, 500 c.c. of which, when evaporated to dryness, gave no residue.

The hydrobromic acid used contained 40 per cent of real acid, and was prepared by immersing ordinary white phosphorus in soft paraffin, and adding bromine, which, if this method be employed, combines with the phosphorus without any fear of explosion: water was then added drop by drop, when hydrobromic acid was liberated, and may be distilled in a perfectly pure state. The well-known reaction is explained by the following equation:—

$$P+5Br+4H_2O=5HBr+H_3PO_4.$$

The same method was employed for the preparation of pure hydriodic acid, the equation in this case being—

$$P+3I+3H_2O=3HI+H_3PO_3.$$

Having thus obtained reliable acid and sulphate of barium, the solubility of the latter was found by taking 100 c.c. of hydrobromic acid in a flask, and adding 1 grm. of sulphate of barium. This was then boiled for a quarter of an hour on a sand-bath, and then filtered, receiving the clear filtrate in the 100 c.c. flask, which was then filled to the graduated mark with distilled water; this was then divided into two equal portions of 50 c.c. each, and evaporated to dryness. The residue was found to weigh in each case 0·02 grm., which represents a solubility of $\frac{1}{50}$. A similar experiment was made with hydriodic acid, which showed the sulphate of barium to be much less soluble in it than in the hydrobromic acid: the residue weighed in this case only 0·008 grm., which shows a solubility of $\frac{1}{125}$.

Dublin, February 11, 1886.

DETERMINATION OF IRON AND ALUMINA IN PHOSPHATES.

By E. W. T. JONES, F.I.C.

The following method for the above-named object has been practised by me, when needed, for the last twenty years. In my opinion it is better than the procedure described by Mr. Dyer (Chemical News, vol. liii., p. 51), because it yields a direct determination in each case with very little trouble.

Dissolve from 1 to 2 grms. of the phosphate in hydrochloric acid, evaporate to dryness, take up again with hydrochloric acid and water, filter, oxidise with nitric acid if necessary, nearly neutralise with ammonia, dilute if necessary to about 200 c.c., warm the solution, and pour into 100 c.c. of hot solution of ammonic acetate acidified with 10 c.c. of ordinary strong acetic acid; allow to stand a time for the precipitate to subside, then filter, wash with hot water, dropping on to the filter from time to time some solution of ammonic acetate; filtration and washing then proceed satisfactorily. The requisite amount of washing having been accomplished, pierce the filter and wash the precipitate into a beaker, finally clearing the filter by dropping some hydrochloric acid round it, and further rinsing; make the solution hot, nearly neutralise with some solution of pure caustic potash, and pour *into* about 50 c.c. of solution containing 4 to 5 grms. of pure KHO *boiling* in a silver dish. *Boil* a few minutes and filter, wash the oxide of iron, dissolve in HCl, reduce with stannous chloride, and titrate with standard dichromate solution. Warm the filtrate from the oxide of iron and add acetic acid till a precipitate just begins to form, and then add it to 50 c.c. of heated solution of acetate of ammonia acidified with 5 c.c. of acetic acid; allow to stand a short time, then filter and wash thoroughly with hot water, using from time to time some drops of ammonic acetate, or filtering and washing become tedious; the precipitate, being dried and ignited, is weighed as $Al'''PO_4$: in this way the orthophosphate is always precipitated, and the composition may be relied on.

To illustrate the practical applicability of the method I weighed out 2 grms. of bone-ash, dissolved in HCl and filtered, added 0·5 grm. alum and 0·5 grm. ferrous ammonic sulphate, oxidised with HNO_3 diluted to about 200 c.c., nearly neutralised with AmHO, warmed and poured into 100 c.c. of hot ammonic acetate acidified with 10 c.c. of acetic acid, and proceeded as described above. I obtained 0·0702 grm. iron against 0·0692 grm. added (the amount by careful experiment 0·5 grm. of the double salt was found to contain). Of phosphate of alumina I got 0·1270 grm.: this equals 0·0534 Al_2O_3 against 0·0580, the amount half a gramme of the alum gave by careful direct precipitation.

Two grms. of the bone-ash by itself, treated the same way, gave only 0·0050 grm. of precipitate after standing all night: this proved to be iron, and was allowed for in the above estimation.

I may mention that I weigh the alumina from iron ores as phosphate, and find the proceeding very satisfactory.

N.B. I make the ammonic acetate solution by neutralising ordinary strong acetic acid with 0·960 ammonia.

ON A

REAGENT PERMITTING THE DETECTION OF THE ACID FUNCTION OF WEAK ACIDS.

By M. R. ENGEL.

It has long been known that the neutralisation of the different acids is not manifested in the same manner by the different colouring-matters (litmus, cochineal, hæmatoxyline). The theoretical reasons in virtue of which the strong acids are recognised by their reaction upon the tincture of litmus have been developed by M. Berthelot (*Mecanique Chimique*, ii., p. 204). Subsequently M. Miller (*Berichte*, 1878, p. 460) has shown that certain salts which turn litmus blue are without action upon tropæoline. Mr. R. T. Thomson (Chemical News, vol. xlix., p. 123) has shown that orange 3 defines phosphoric acid as monobasic, whilst phenacetoline and especially phenolphthaleine define it as bibasic. M. Joly (*Comptes Rendus*, 1885, c., p. 55) has called attention to the same facts.

Lastly, M. Berthelot, by recent calorimetric experiments, has fully explained the question, showing that helianthine A characterises the neutralisation of every acid the formation-heat of whose solid potassium-salt exceeds 10·2 cals., whilst helianthine B and phenol-phthaleine enable us to titrate every acid the formation of whose solid potassium-salt exceeds 6 to 7 cals.

The soluble blue (Poirrier's CLB), a colouring-matter to which M. Ville and the author have called attention, permits the direct titration in the cold of alkaline bases in presence of their carbonates, and indicates the neutralisation of acids which evolve still less heat with potassa, though it has not been possible to fix the lower limit of this source of this quantity of heat, the potassium-salts of most of the bodies in question not being known in the solid state.

This reagent serves not merely for certain determinations, but also as a means of demonstration in lectures. It shows distinctly the acid function of certain organic compounds of mixed functions which are neutral, or even alkaline, with litmus, and with the aid of orangé 3 and of phenol-phthaleine it shows the relative thermic energy of various acids, and the several distinct energies of most polybasic acids.

Experiments have been made as follows:—Take a quantity of the substance equal to its molecular weight, to the half or to the tenth of such weight; the solution is diluted to 1 litre, so as to have normal, seminormal, or decinormal solutions, according to the solubility of the substance. These liquids are titrated with normal potassa, having added a few drops of the solution of soluble blue at $\frac{1}{100}$. To distinguish the end of the reaction it is well to operate in a beaker of Bohemian glass set on a white ground, the depth of the liquid to be titrated not exceeding a few m.m. When the last three- or four-tenths of a c.c. of the solution of potassa to be added are reached, the blue colour begins to change alike with strong and with weak acids; but on operating as just described each drop of potassa falling in the centre of the vessel gives a violet-red tint, which stands out distinctly against the general tint of the liquid. The addition of potassa is continued until a drop no longer occasions any change of colour, but merely a difference in intensity of the same colour, scarcely visible and due to the dilution of the liquid at the place where the drop falls.

1. *Phenol.*—Phenol, in presence of which litmus and orangé 3 turn at once under the influence of a single drop of potassa, and helianthine B turns progressively, behaves with the blue like a monobasic acid. Just as certain strong acids do not redden litmus in presence of alcohol, phenol in an alcoholic solution does not act upon the soluble blue if previously reddened by a drop of potassa.

2. *Resorcin* is distinctly characterised as a bibasic acid. This result is conformable to the recent experiments of MM. Berthelot and Werner on the neutralisation heat of resorcine by soda.

3. *Morphine.*—It was particularly interestin to ascertain if morphine which possesses the double phenol function manifests these functions in presence of "soluble blue." The results were most decisive. Morphine behaves like an acid; but on account of the sparing solubility of the free base the author was obliged to prepare a standard solution with its hydrochlorate: 100 degrees of a decinormal solution of morphine hydrochlorate required 24 degrees of potassa (theoretically 20 degrees for the double phenol function). Thus, for neutralisation it requires a quantity of potassa slightly greater than that indicated by theory. The author ascribes this result to a division of the hydrochloric acid between the potassa and the morphine which as a base no longer acts upon the colouring-matter. The author and M. Ville have pointed out that ammonia does not turn the soluble blue to a red. It is the same with ethylamine and the other amines, and doubtless also with morphine naturalised in its functions as phenol. However this may be, it is easy to show in a striking manner the acid function of phenol, either with the free alkaloid or its hydrochlorate.

4. *Monovalent Alcohols.*—Soluble blue is turned by a single drop of potassa in presence of monovalent alcohols, even if tertiary alcohols (trimethyl-carbinol and pinacone) are simultaneously present, which in many respects approach the phenols, but which are clearly distinguished by this character. There is room to examine the non-saturated fatty acids of the fatty series from this point of view.

5. *Polyvalent Alcohols.*—In strong solutions glycerin, erythrite, mannite, &c., show an acid tendency. Several drops of potassa are needed to reach the red tint, which may be brought back to a blue by an excess of the polyvalent alcohol, but their titration is not possible.

6. *Ordinary Aldehyd* is turned by a single drop of potassa.

7. *Chloral* is perfectly capable of titration. It behaves like a monobasic acid. As chloral when decomposing under the influence of potassa yields chloroform and a mol. of monobasic formic acid, there is no reason to inquire in this determination whether decomposition takes place or not. This method is quite practical, and may serve to show the value of a commercial chloral.

8. *Hydrocyanic Acid* may also be determined acidimetrically, using soluble blue as an indicator. The results are excellent. Glycocoll, alanine, and taurine behave as acids. The determination of these substances, which is of no interest, does not seem practicable, because towards the limit the change is effected gradually, and the colouration of the liquid tends to disappear; but the acid function of these bodies, which are at once acids and bases, is shown very distinctly.—*Comptes Rendus*, cii., p. 214.

CONTROL ANALYSES AND LIMITS OF RECOVERY IN CHEMICAL SEPARATIONS.*

By ALBERT B. PRESCOTT.

(Concluded from page 79).

FINALLY, the summary next given may be further defined, in comparison of limits of separation with limits of identification, as follows, namely: The loss in separating from an avoirdupois pound of tissues is, for arsenic, in round terms, about a thousand times the quantity needed for certain identification; and for strychnine, from one thousand to two thousand times such least quantity. For morphine, both limits are less definite, and decomposition losses interpose, and the data obtained do not warrant an assured statement. But in the results here given the loss of alkaloid, per pound of tissues, was about 100 times the quantity needed for identification.

Summary of Limits of Recovery.

Limits of Recognisable Precipitation.

The first production of a precipitate, in a mixture made by adding one solution to another, is a constant not agreeing very closely with that of the so-called solubility of the substance precipitated. The proportion of solvent needed to dissolve a solid may differ a good deal from the proportion of the same solvent present at the incipient precipitation of the solid. In other words, the equilibrium between precipitation and solution may offer a good deal of resistance—just as the melting point may be removed some degrees from the congealing point. It is true that the factor of solubility is usually—perhaps incorrectly—defined as the ratio obtained when a supersaturated solution, left at a certain temperature for a certain time, has deposited its excess of dissolved substance. Moreoiver, the causes of variable solubility of solids are very illusive.

Results in illustration of such variability were given to this Association by the writer in 1875. Indeed our ideas of solubilities are in a suggestive stage, l ading us toward the unknown border between adhesion and chemism.

It appears to the writer that the fact of the initial appearance of a precipitate when one given solution is added to another, in stated conditions, may be taken as a constant by itself—not to be calculated from other constants but to be determined by experiment. Initial precipitation is governed by the concentration of the substance precipitated, by the presence of and concentration of other dissolved substances, and by temperature and time. That is, with temperature and time we have relations of mass too complex for calculation now, but easily made constant in experiment. Now if we fix the temperature and time, the quantity of the one solution with its components and their concentration, and fix the quantity of the other solution and know its components, then the concentration of these components becomes constant in parallel operations. In short, by controlling the given factors, a simple qualitative test may be made to show whether a required percentage is at, or above, or below a required limit. This way of using qualitative tests, with measured quantities, temperatures, and times, to reach quantitative indications, is a resource becoming more and more common in analytical work. It is made available in the later revisions of the pharmacopœias. For instance, in the U. S. Ph. "If one grm. of bitartrate of potassium be digested with 5 c.c. of diluted acetic acid for half an hour, then diluted with distilled water to 500 c.c., the solution agitated and filtered, and 25 c.c. of the filtrate treated with 5 c.c. of test-solution of oxalate of ammonium, the liquid should not become cloudy in less than one minute, nor distinctly turbid in less than one minute and

a half (absence of more than 6 per cent of tartrate of calcium)." Likewise we have the test (Kerner's) of sulphate of quinine for other cinchona alkaloids, of iodide of potassium for chloride and bromide, and of bicarbonate of sodium for monocarbonate.

Two years ago, in an inaugural thesis for the master's degree in the University of Michigan, Delos Fall reported determinations of the limits of precipitation. His work embraced 241 satisfactory experiments, defining 48 limits in formation of 24 precipitates. The limits were chiefly determined for the time of five minutes. There is a wide field for work of this character. It gives support to studies in molecular science: it fixes data of service in daily operations; and it defines factors by which a ready trial reveals required limits of strength and purity of materials. In the tests by Mr. Fall, 25 c.c. of the solution of known strength of a single salt were taken; 5 c.c. of a reagent of given strength added, in a test-tube 2 c.m. wide, and the depth of the liquid was made to be 9 c.m. The temperature was noted, and observations for incipient precipitation were taken at stated times. The beginning of precipitation was recognised, in most cases, by observing a figure of thirty-five dotted parallel lines to the inch, looking through the same depth of water to which same quantity of reagent had been added for comparison. I quote selections of Mr. Fall's tabulated reports, to present the method of investigation, and the character of the results reached. I hope he and others may continue the work, and that the whole may have publication at a future time.

ON THE TRANSFER OF COPPER THROUGH A GASEOUS STRATUM AND ON A DIRECT COMBINATION OF COPPER AND NITROGEN.

By R. BLONDLOT.

In the course of experiments undertaken with the object of studying the passage of electricity through incandescent gases the author has had the opportunity of making the following observations.

A platinum disc and a disc of copper of 0·03 metre in diameter were fixed perpendicularly opposite to each other by means of supports consisting of two platinum columns. The mutual distance of the discs was 3 or 4 m.m. The whole was placed in the interior of a glazed porcelain bell, the mouth of which, turned downwards, remained free.

The apparatus having been raised to a bright red heat for about three hours by heating the bell from above by means of a gas-furnace, it was perceived, in the absence of any electric current, that the surface of the platinum disc turned towards the copper had totally changed its aspect—there was formed on it a coating of about $\frac{1}{15}$ m.m. in thickness having the colour of graphite. Having scraped off a portion of this layer by means of a fragment of glass the author found that it was insoluble in cold nitric acid but soluble in this acid if heated, leaving, however, a residue of a black powder. The dissolved portion contained considerable quantities of copper, though the platinum of the disc contained mere traces. The black powder was very active platinum black.

Thus there had taken place the formation, at a distance, of a chemical compound containing copper and platinum. That is to say the copper had traversed the interval which separated the two discs. As often as the experiment was repeated it yielded the same result.

In this experiment the copper was strongly oxidised. To decide whether or not this oxidation played a part in the phenomenon the experiment was repeated in pure nitrogen. A porcelain tube, glazed within and without, had cemented to its two extremities metallic fittings, kept constantly cooled by the circulation of water. To each of them was fixed a platinum column, directed towards the interior of the tube along its axis. These two columns were terminated respectively by discs of platinum and copper, which were thus placed opposite to each other in the middle of the tube. A slow current of pure nitrogen prepared by Schlœsing's method was passed slowly into the tube for twelve hours and the tube was then heated to bright redness for four or five hours. The transference of copper was invariably observed and at the same time the copper disc was evidently corroded. Its surface remained perfectly brilliant, but it showed the uncovered facets of an internal crystallisation. It was inferred from this experiment that oxygen played no part in the phenomenon.

To ascertain if it was the same with nitrogen the experiment was repeated in pure hydrogen. The result was always negative. The experiment, repeated several times, under the most favourable conditions never gave rise to the slightest transfer. It is therefore nitrogen which plays the principal part in the transfer of the copper. In all probability there is formed a direct compound of nitrogen and copper, which is either directly incorporated in its totality with the platinum or is decomposed on contact with the latter, yielding to it its copper.

The author has found that the copper-compound deposited upon the platinum can be dissociated under the influence of a very elevated temperature. Having had occasion to heat in nitrogen a column of platinum covered with the copper compound, he found that this latter was transferred from the hottest up to the coldest parts of the column. The existence of the dissociation is further confirmed by the following fact. On operating in an open bell, according to the first process indicated, whilst the surface of the platinum turned towards the copper was covered with a thick layer of the copper compound, the posterior surface was bare. The platinum columns which serve as supports are likewise deprived of it at their upper part, whilst they are abundantly coated below. This distribution is thus explained: In the interior of the bell, the temperature being very high, the tension of dissociation is very great, and the compound cannot be formed save in the immediate neighbourhood of the source of the copper. On the contrary, towards the bottom the temperature is lower, and the compound may be formed on the lower part of the columns.—*Comptes Rendus*, vol. cii., p. 210.

LONDON WATER SUPPLY.

REPORT ON THE COMPOSITION AND QUALITY OF DAILY SAMPLES OF THE WATER SUPPLIED TO LONDON FOR THE MONTH ENDING JANUARY 31ST, 1886.

By WILLIAM CROOKES, F.R.S.,

WILLIAM ODLING, M.B., F.R.S., F.R.C.P.,
Professor of Chemistry at the University of Oxford.

and C. MEYMOTT TIDY, M.B., F.C.S.,
Professor of Chemistry and of Forensic Medicine at the London Hospital; Medical Officer of Health for Islington.

To COLONEL SIR FRANCIS BOLTON, *Water Examiner, Metropolis Water Act*, 1871.

London, February 7th, 1886.

SIR,—We submit herewith the results of our analyses of the 177 samples of water collected by us during the past month, at the several places and on the several days indicated, from the mains of the seven London Water Companies taking their supply from the Thames and Lea.

In Table I. we have recorded the analyses in detail of samples, one taken daily, from January 1st to January 31st inclusive. The purity of the water, in respect to organic matter, has been determined by the Oxygen and Combustion processes; and the results of our analyses by these methods are stated in Columns XIV. to XVIII.

We have recorded in Table II. the tint of the several samples of water, as determined by the colour-meter described in a previous report.

In Table III. we have recorded the oxygen required to oxidise the organic matter in all the samples submitted to analysis.

Of the 177 samples examined, the whole were found to be perfectly clear, bright, and well filtered.

Despite the flooded state of the rivers, consequent on the thawing of the late heavy fall of snow, there was not any appreciable increase in the proportion of organic matter present in the water-supply of the month; the mean amount of organic carbon found in the Thames-derived supply being 0·183 part in 100,000 parts of the water as against a mean amount of 0·170 part in the preceding month. The increased storage capabilities and improved filtering arrangements now available to the Companies, seem to have rendered the effects of the varying state of the river itself, for the most part, far less marked than was commonly noticeable even but a few years ago.

The general result of our daily examinations of the water-supply of the Metropolis, carried on now for a period of five years, has been to establish its uniformly excellent state of aëration, and its habitual and increasing degree of freedom from turbidity, colour, and excess of organic matter. As regards the uniformly complete state of aëration of the water, considering its high character in this respect to be now established beyond question, we have deemed it unnecessary to continue any longer our determinations and records of the quantities of free or dissolved oxygen present per gallon.

For some time past we have been directing our attention to the examination of the water of the Metropolis by so-called biological methods, from the application of some of which, at any rate, results of importance may doubtless be ultimately arrived at; but several months at least may be expected to elapse before we shall be in a position to include any results furnished by this manner of examination in our ordinary reports. In justification of our caution in the matter, we think it only right to observe that the chief authorities in bacteriology in this country are not satisfied as to the trustworthiness even of the methods of biological examination, as yet practised by chemists; while having regard to the fact that every breath of air we draw is laden with so-called germs, they look upon the estimation of the number of germs in a given volume of water, irrespective of any determination of the beneficent or pathogenetic nature of these germs, as a result from which no hygienic inference of any kind can be drawn.

We are, Sir,
Your obedient Servants,

WILLIAM CROOKES.
WILLIAM ODLING.
C. MEYMOTT TIDY.

CONTRIBUTIONS TO THE KNOWLEDGE OF SAMARIUM.*

By P. T. CLEVE.

(Continued from p. 82).

Carbonate of Samarium and Ammonium, $Sm,NH_4,2CO_3 + 2H_2O$.

The voluminous and amorphous precipitate which carbonate of ammonium gives with the nitrate of samarium changes after some time into a heavy powder consisting of small rounded granules, provided it be left at the ordinary temperature in presence of an excess of carbonate of ammonium. Only a trace of samarium remains in the solution. Heated to 100° the salt loses water and ammonia. The compound was pressed between filter-paper and analysed.

0·8269 grm. was dissolved in hydrochloric acid and precipitated with tetrachloride of platinum, when 0·6224 grm. $(NH)_2PtCl_6$ was obtained. From the filtrate the platinum was precipitated with H_2S and 0·4368 grm. Sm_2O_3 obtained as oxalate.

In per cent—

		Calculated.	
Sm_2O_3	52·82	348	53·70
$(NH_4)_2O$	8·81	52	8·02
CO_2	—	176	—
H_2O	—	72	—
		648	

Carbonate of Samarium and Sodium, $Sm,Na,2CO_3 + 8H_2O$.

The nitrate of samarium gives with an excess of carbonate of sodium a voluminous and amorphous precipitate which soon changes into a yellowish white powder consisting of microscopic crystalline aggregates. Only small traces of samarium remain in the solution. The salt was pressed between filter-paper and analysed. Heated in air-bath to 100° the compound loses 6 mols. H_2O (found 24·54 and 24·69; calculated 24·71 per cent).

0·4360 grm. gave 0·1751 grm. Sm_2O_3 and 0·0651 grm. NaCl.

In per cent—

		Calculated.	
Sm_2O_3	40·16	348	39·82
Na_2O	7·91	62	7·09
CO_3	—	176	—
H_2O	—	288	—
		874	

Borate of Samarium, $SmBO_3$.

Borax at a white heat easily dissolves the oxide of samarium and gives a topaz-coloured glass, from which, when completely saturated with the oxide, and after heating to a red heat, very thin micaceous brilliant microscopic scales separate. After cooling the glass was reduced to a coarse powder and treated with dilute hydrochloric acid, which left the borate as a chalk-like powder. The borate is readily soluble in hydrochloric acid, especially on heating, so that the isolation of the borate from the excess of borax-glass requires very careful treatment.

0·9137 grm. was dissolved in hydrochloric acid, the solution repeatedly evaporated and finally mixed with oxalic acid. After igniting the oxalate 0·7602 grm. Sm_2O_3 was obtained.

1·8695 grm. gave 1·5557 grm. Sm_2O_3.

In per cent—

			Calculated.	
Sm_2O_3	83·20	83·21	174	83·25
B_2O_3	(16·80)	(16·79)	35	16·75
	100·00	100·00	209	100·00

1·4490 grm., t° 16·4°, sp. gr. 6·045
1·4226 „ „ „ 6·052

Mean of both determinations, 6·048.
Molecular volume, 34·6.

Sum of the molecular volume of Sm_2O_3 and B_2O_3, divided with 2 = 40·0.

Orthophosphate of Samarium, $SmPO_4$.

This phosphate was obtained by dissolving the oxide of samarium in melting metaphosphate of sodium. A topaz-

* Presented to the Royal Society of Sciences of Upsala, Feb. 13, 1885.

coloured glass was thus produced which on cooling became enamel-like, owing to the formation of small, but well formed, short prismatic crystals. The mass was treated with water, the crystals being thus obtained as a heavy crystalline whitish yellow powder. The salt is scarcely attacked by boiling nitric acid. In order to analyse it the salt was decomposed by fusion with soda. Some phosphoric acid always remains with the oxide of samarium, so it is quite indispensable to dissolve the oxide in nitric acid and to precipitate with oxalic acid.

0·7840 grm. gave 0·5591 grm. Sm_2O_3 and 0·3311 grm. $Mg_2P_2O_7$.

0·6114 grm. gave 0·4354 grm. Sm_2O_3.

0·3400 grm. gave 2·5365 grm. phospho-molybdate of ammonia.

In per cent—

				Calculated.	
Sm_2O_3	71·31	71·21	—	174	71·02
P_2O_5..	27·01	—	27·83	71	28·98
				245	100·00

Specific gravity—

1·3611 grm., t° 17·5°, sp. gr. 5·830
1·1194 „ „ „ 5·826
Mean of both determinations, 5·828.
Molecular volume, 42.

Disodium orthophosphate gives with nitrate of samarium a bulky, white, and amorphous precipitate which can only be washed with difficulty and easily passes through the filter. When dried it forms white hard pieces. The precipitate, dried in the air at ordinary temperature, gave on analysis :—

0·4203 grm. lost at 100° 0·0290 grm. and in red hot 0·0317 grm. It gave, melted with carbonate of sodium, 0·2494 grm. Sm_2O_3 and 0·1760 grm. $Mg_2P_2O_7$.

In per cent—

	Dried in the air.	Dried at 100°.
Sm_2O_3	59·34	63·74
P_2O_5	26·78	28·77
H_2O	14·44	8·10
	100·56	100·61

The simplest formulæ which correspond to this composition are :—

		$SmPO_4 + 2H_2O$.		$SmPO_4 + H_2O$.	
Sm_2O_3	174	61·92	174	66·16
P_2O_5..	71	25·27	71	27·00
H_2O..	36	12·81	18	6·84
	281	100·00	263	100·00

The differences between the numbers found by analysis and those calculated from the formulæ are considerable, but one could not expect better from a substance such as the amorphous phosphate, the composition of which may vary. In any case the composition indicates that the precipitate which disodium orthophosphate gives with salts of samarium is principally composed of trimetallic phosphate.

Pyrophosphate of Samarium,

$$\left.\begin{matrix}Sm\\H\end{matrix}\right\}O_4,P_2O_3+3\tfrac{1}{2}H_2O.$$

Pyrophosphoric acid easily dissolves the hydrate of samarium, and the solution deposits after some time, on spontaneous evaporation, small compact granules of densely crowded crystals. The salt loses at 100° 10·79 per cent H_2O, corresponding to 2 mols. H_2O (calc. 9·28 per cent).

0·4456 grm. salt, pressed between filter-paper, lost on ignition 0·0800 grm. H_2O.

0·4118 grm. was dissolved in nitric acid and the solution boiled. On adding oxalic acid 0·1852 grm. Sm_2O_3 was thrown down as oxalate. From the filtrate 0·2348 grm. $Mg_2P_2O_7$ was obtained.

In per cent—

		Calculated.

	99·39	776	100·00

Anhydro-metaphosphate of Samarium, $Sm_2O_3 5P_2O_5$.

If the anhydrous and finely-powdered sulphate of samarium be added to fused metaphosphoric acid it dissolves easily, fumes of sulphuric acid being given off. The residue soon becomes white owing to the formation of small crystals. After cooling the mass was treated with water, which dissolved the phosphoric acid and left a heavy yellowish white powder of small glittering crystals insoluble in water and in boiling nitric acid. The crystals were very well developed. They represent a new series of phosphates. Didymium gives an exactly analogous phosphate.

0·6425 grm. was fused with soda and the fused mass treated with water. The solution was precipitated with magnesia-mixture and the residue dissolved in nitric acid and precipitated with oxalic acid. By igniting the oxalate 0·2150 grm. Sm_2O_3 was obtained. The filtrate from the oxalate contained phosphoric acid, which was precipitated as ammonium-magnesium phosphate. Altogether 0·6678 grm. $Mg_2P_2O_7$ was obtained.

0·9672 grm. gave 0·3195 grm. Sm_2O_3 and 1·0138 grm. $Mg_2P_2O_7$.

Vanadates of Samarium.

The neutral solutions of the salts of samarium and alkaline metavanadates give a light yellow perfectly amorphous precipitate consisting for the greater part of hydrated orthovanadate of samarium. The numbers found on analysis did not agree sufficiently well with those calculated to make me think it worth publishing them. If a solution of bivanadate of sodium be mixed with a solution of the nitrate of samarium, a yellowish amorphous precipitate is thrown down, probably the orthovanadate of samarium, and from the filtered solution on spontaneous evaporation at the ordinary temperature two different sets of crystals are obtained. The one set has the colour of bichromate of potash, and the other a more yellow colour. Both form large, extremely beautiful crystals.

A. *The Red Salt*, $Sm_2O_3,5V_2O_5+28H_2O$.

0·3760 grm. lost, on heating to 100°, 0·0864 grm. H_2O, and at incipient redness 0·0196 grm. more. The anhydrous salt was dissolved in HCl and reduced with SO_2. On adding oxalic acid and igniting the oxalate 0·0726 grm. Sm_2O_3 was obtained. The filtrate from the oxalate of samarium was evaporated to dryness, and the residue carefully heated so as to volatilise the excess of oxalic acid. It was then oxidised with very dilute nitric acid, evaporated to dryness, and heated so as to melt the vanadic acid, the weight of which was found to be 0·1953 grm., but which, however, contained 0·0027 grm.

Sm_2O_3. The analysis had thus given 0·1926 grm. V_2O_5 and 0·0753 grm. Sm_2O_3.

Molybdate of Samarium, Sm_23MoO_4.

A neutral solution of the nitrate of samarium gives with an excess of molybdate of ammonia ($6NH_4,Mo_7O_{24}$) a voluminous white precipitate which, if warmed, is changed into a heavy granular non-crystalline powder. Much samarium remains in solution. As the salt was amorphous it was not subjected to analysis. In order to obtain crystalline molybdate calculated quantities of molybdic acid and oxide of samarium ($Sm_2O_3 : 3MoO_3$) were mixed with pure chloride of sodium and heated in a large platinum crucible for some hours to bright red heat. After cooling the mass was treated with water, which left 1:0 heavy violet-coloured very brilliant crystals, 2:0 fine microscopic needles, and 3:0 brilliant scales, resembling boracic acid, insoluble in ammonia and slowly soluble in hydrochloric acid; of 3 only a small quantity insufficient for analysis was obtained. The two other sets of molybdates could be pretty completely separated by elutriation. The heavy crystals were neutral molybdate of samarium and the light needles (2) a molybdate of samarium and sodium.

The molybdate of samarium, Sm_23MoO_4, formed small rhombic octahedrons and combinations of the horizontal and vertical prisms. Some crystals attained a length of ¼ to $\frac{1}{10}$ of a millimetre. They had a diamond lustre and a dark violet colour, occasioned by a trace of molybdic oxide. Heated in the air they became white. They were very slowly decomposed by hydrochloric acid. The sp. gr. was 5·95, but this number is only approximate as the salt was not pure. The analysis gave 47·4 per cent Sm_2O_3 instead of 44·62 per cent.

Molybdate of Samarium and Sodium, $SmNa2MoO_4$.

As described above, thin microscopic needles of this salt were obtained along with the neutral molybdate of samarium by fusing molybdic acid and oxide of samarium with chloride of sodium. Separated from the neutral salt by elutriation it formed a voluminous woolly mass of a dirty violet colour, which colour disappeared on gently heating in the air. Warm dilute hydrochloric acid dissolves this salt easily.

0·4402 grm. gave 0·1518 Sm_2O_3 and 0·0597 grm. NaCl.

In per cent—

		Calculated.	
Sm_2O_3	34·48	174	35·29
Na_2O	7·19	31	6·29
MoO_3	(58·33)	288	58·42
	100·00	493	100·00

Sp. gr. = 5·265 at 18° as mean of two determinations. As the salt was not perfectly pure this number may be regarded as only an approximation.

Tungstate of Samarium and Sodium, $Sm_4Na_69WO_4$.

Was obtained by Mr. Högbom,* who heated tungstic acid with a corresponding quantity of the oxide of samarium in an excess of chloride of sodium. The salt forms brown microscopical crystals. The analysis gave:

		Calculated.
Sm_2O_3	25·62	23·43
Na_2O	6·10	6·26
WO_3	68·16	70·31

The salt contained as impurity a little of oxide of samarium.

Metatungstate of Samarium.
$Sm_2O_3,12WO_3 + 35H_2O$.

Metatungstate of barium was decomposed with a calculated quantity of sulphate of samarium and the solution evaporated over oil of vitriol. From the very concentrated solution large topaz-yellow and well-formed crystals were obtained. The salt is easily soluble, but not deliquescent. It becomes opaque when exposed to light. It loses at 100° 12·21 per cent H_2O, or 25 mols. H_2O (calc. 11·96).

I. 1·4985 grm. salt, pressed between filter-paper, lost, on heating nearly to redness, 0·2510 grm. H_2O, and gave on decomposition with concentrated sulphuric acid 1·0995 grm. WO_3. From the filtrate from the tungstic acid 0·1394 grm. Sm_2O_3 was precipitated as oxalate.

II. 1·1556 grm. lost on heating 0·1951grm. H_2O, and gave, when decomposed with hydrochloric acid, 0·8504 grm. WO_3 and 0·1088 grm. Sm_2O_3 precipitated as oxalate.

In per cent—

	I.	II.	Calculated.

PROCEEDINGS OF SOCIETIES.

PHYSICAL SOCIETY.

Annual General Meeting, February 13th, 1886.

Prof. F. GUTHRIE, President, in the Chair.

PROF. T. H. Huxley and Mr. A. E. Mills were elected Members of the Society.

The PRESIDENT read the Report of the Council.

The Treasurer, Dr. E. ATKINSON, presented his Report, which was adopted.

The Meeting resolved that votes of thanks be accorded to—

The Committee of the Council of Education;
The President and Officers of the Society;
The Auditors of the Society's accounts.

The Meeting then proceeded to elect Officers for the forthcoming year, and a ballot having been taken the following were declared elected:—

President—Dr. Balfour Stewart, LL.D., F.R.S.

Vice-Presidents—Dr. J. H. Gladstone, F.R.S.; Prof. G. C. Foster, F.R.S.; Prof. W. G. Adams, F.R.S.; Sir W. Thomson, D.C.L., F.R.S.; Prof. R. B. Clifton, M.A., F.R.S.; Prof. F. Guthrie, Ph.D., F.R.S. (the above have filled the office of President); Prof. W. E. Ayrton, F.R.S.; Shelford Bidwell, M.A., LL.B.; Prof. H. McLeod, F.R.S.; Prof. W. Chandler Roberts-Austen, F.R.S.

Secretaries—Prof. A. W. Reinold, M.A., F.R.S.; and Walter Baily, M.A.

Treasurer—Dr. E. Atkinson.

Demonstrator—C. Vernon Boys.

Other Members of Council—Conrad W. Cooke; Prof. G. Forbes, F.R.S.E.; Prof. F. Fuller, M.A.; R. T. Glazebrook, M.A., F.R.S.; J. Hopkinson, D.Sc., F.R.S.; Prof. J. Perry, F.R.S.; Prof. J. H. Poynting, M.A.; Prof. A. W. Rücker, M.A., F.R.S.; Prof. S. P. Thompson, D.Sc.; C. R. Alder Wright, D.Sc., F.R.S.

Professor GUTHRIE, in resigning the position of President, thanked his colleagues for the help they had afforded him since he became President of the Society in 1884. He also congratulated the Society upon the highly satisfactory state to which it had attained.

The Meeting then resolved itself into an Ordinary Meeting.

In the absence of the President, Prof. Balfour Stewart, the chair was occupied by Prof. G. C. FOSTER.

The following communications were read:—

"*On Experimental Error in Calorimetrical Work*," and "*On Delicate Calorimetrical Thermometers.*" By Prof. S. U. PICKERING.

In conducting a great number of determinations of the heat of dissolution of a solid body in water, the author has had an opportunity of detecting the sources of error incident on such work, and by an examination of the results has not only obtained the mean error of a series of observations, but has been able to apportionate this error to its various causes. In the experimental work it was found that the presence of anything but air between the calorimeter and jacket was most injurious; the space should be entirely open, and no cover of any sort should be used. Before reading the thermometers, as pointed out by Berthelot, the top of the stem should be tapped for some time, otherwise the mercury lags behind the true temperature; but besides this thermometric error, which the author calls the "temporary error," is another effect which may be termed the permanent error, of a similar kind, which no amount of tapping will remove. He has found and verified by special experiments that a thermometer when rising is invariably too low, while when falling it is invariably too high. The error due to this, which varies in amount with different instruments, is avoided by conducting the whole experiment with a rising or with a falling thermometer. The thermometers employed in these experiments had a range of 15° C. and a total length of 600 m.m. The experiments were performed at temperatures varying from −1° to 26° C., and, as it was important that the same thermometer should be used in different experiments, and even advisable to use the same part of the scale of the thermometer, the following expedient was devised:—The thermometer was first heated to the highest temperature required in the experiment, and by the application of a flame to the mercurial column, just below the enlarged space at the end of the tube, that part of the mercury above the flame was broken off and driven into the space where it remained when the thermometer was cooled. By this means the relative value of a scale division was only inappreciably affected, while the absolute value could be obtained from a single comparison with a standard. From an examination of the results obtained, the author concludes that for further accuracy in this kind of work we must look for improvements in the methods employed, the instruments having, he believes, attained to a state as near perfection as possible.

"*On some New Forms of Calorimeters.*" By Prof. W. F. BARRETT.

These instruments were constructed for accurate and ready determinations of specific heats, notably those of liquids. In the first form the bulb of a thermometer is blown into the form of a cup, of about 4 c.c. capacity, which thus acts as a calorimeter. Into this cup the liquid is dropped directly from a burette, its temperature being observed by a thermometer in the burette, the mouth of which is closed by the end of the bulb of the thermometer, which is ground, and thus acts the part of a stopper, so that on raising the thermometer the liquid flows from the burette into the cup. The thermometer itself forms a balance; the horizontal stem acting as the beam is supported by a knife edge, and a pan is attached to the further end by the addition of weights to which the weight of liquid added can be ascertained. In the second form a simple thermometer with a large bulb is used, the latter dipping into a silver vessel into which the liquid is introduced as before.

Prof. S. P. THOMPSON exhibited a glass calorimeter, similar in construction to that of Favre and Silbermann; water is used instead of mercury, the great density of which renders it unsuitable for use in so large a glass vessel.

NOTICES OF BOOKS.

Chemical Equilibrium, the Result of the Dissipation of Energy. By G. D. LIVEING, M.A., F.R.S., Professor of Chemistry in the University of Cambridge. Cambridge: Deighton, Bell, and Co. London: G. Bell and Sons.

THE theory of matter here put forward is avowedly an outcome of the vortex theory, with which it must stand or fall. Prof. Liveing has found in his practical experience that the notion of impenetrable atoms adhering together is "a great hindrance to the acceptance of any views of chemical action founded on sound mechanical principles," and he accordingly makes the present attempt. He seeks to show that it is a consequence of the law of dissipation of energy that given elements, if brought together, should arrange themselves in certain groups of combination. To the pure chemist—as distinguished from the physicist and from what we may call the physico-chemist—the author's views will be made most clearly apparent on examining the last chapter. Here we find it argued that chemical combination is due not to "bonds which have to be untied from one union before they can be tied together again in a new one, nor yet to any special force of chemical affinity peculiar to each element, and satisfied,

whatever that may mean, or disappearing in its combinations." To Prof. Liveing, on the contrary, combination consists "in a harmony of the motions of the combined atoms in virtue of which they move and vibrate together, and that such harmony is brought about by the general force in Nature which compels to an equal distribution of energy throughout the universe. For the notion that the variety of parts which one element can play in combination depends on the variety of modes of vibration which it is capable of taking up, a certain amount of confirmation seems to accrue from spectral observations. Thus elements simple in their chemical relations, such as hydrogen and sodium, give the least complex spectra. Those, on the contrary, which show the greatest changes of valency and play the most varied parts in combination, display the most complicated spectra."

The author asks—"If we attribute combination to an attractive force, how is it possible to explain the fact that it appears to attract one atom of hydrogen to one atom of chlorine, but not two atoms of hydrogen to two of chlorine? How is it that chlorine shows no attraction either for chlorine or hydrogen when it is already combined with hydrogen? Again, why does one atom of oxygen attract two atoms of hydrogen, but show little attraction for one atom?" Such questions, which a little reflection will allow the reader to multiply, are certainly far more easily asked than answered.

Chemical elements, it is here suggested, need not differ in substance one from another, but only in the magnitude and form of structure of their atoms. The author compares hydrogen and oxygen to two bells, made indeed of the same metal, but giving out different notes. Thus the possibility of the chemical combination of two atoms will depend on the possibility of a complete harmony in their movements.

As regards equivalence it is pointed out that this term is used in senses not precisely identical. Thus the equivalence of 1 part hydrogen to 23 parts sodium, 12 magnesium, or 28 ferrosum, is not the same thing as the equivalence of any one of these for 35·5 parts chlorine. If it is said that these same quantities are equivalent to 8 parts of oxygen we have equivalence of a third order, and when we pronounce these several quantities equivalent to 4⅔ parts of nitrogen, or to 3 of carbon, we have a fourth.

The author's object in his present work, which is evidently of a preliminary nature, is not so much to prove his theory as to show that it is, at least, not incompatible with the general principles of chemistry, and, it may be added, to point out that the accepted theory, upon close scrutiny, is by no means free from difficulties. All who are not content to accept the reputed "elements" as ultimate facts will find this book worthy of careful study.

CORRESPONDENCE.

A BENEVOLENT FUND.

To the Editor of the Chemical News.

Sir,—The lamented death recently of two chemists both unhappily leaving widows and children unprovided for suggests strongly the advisability of raising among chemists a permanent fund for the purpose of meeting the needs of such distressing cases. This might well be done under the auspices of the newly chartered Institute of Chemistry. The existing very influential committee of gentlemen belonging to that Institute now called together to further the appeals on behalf of one of the cases affords an unusual opportunity for carrying the project to a successful issue. The existence of such a fund would not stop the flow of benevolence towards cases of special necessity, but would ensure valuable help being rapidly afforded, not only to the families of younger men to whom Providence had denied a life long enough for them to "make a name" or to provide for the wants of those they left behind, but to assist individually those chemists who from various circumstances might find themselves destitute towards Life's evening, after a laborious struggle with the world. I should be happy to subscribe £10 towards such a fund and to add a small annual donation. —I am, &c.,

CHARLES H. PIESSE, F.I.C., &c.,

115, Strand, W.C., Feb. 13, 1886.

CHEMICAL NOTICES FROM FOREIGN SOURCES.

NOTE.—All degrees of temperature are Centigrade unless otherwise expressed.

Comptes Rendus Hebdomadaires des Séances, de l' Académie des Sciences. Vol. cii., No. 5, February 1, 1886.

Thermic Researches on Hypophosphoric Acid.—A. Joly.—The author compares the thermic properties of the two hydrates of hypophosphoric acid with those of the several hydrates of phosphoric and arsenic acids.

Indicators of the various Energies of the Polybasic Acids.—R. Engel.—The author makes a further investigation on the use of Poirrier's blue CLB as an indicator. All the known indicators in presence of boric acid turn under the influence of potassa before the complete neutralisation of the acid. Borax behaves like an alkali with litmus, orangé 3, phenacetolin, and phenolphthaleine (CHEMICAL NEWS, xlvii, p. 135). Soluble blue, on the contrary, only begins to change colour after the complete neutralisation of boric acid. It even indicates the tendency of this acid to combine with a second mol. of potassa. Borax, though alkaline with all other coloured reagents, is acid to soluble blue. Phosphoric acid, monobasic in presence of orangé 3, and bibasic with phenolphthaleine, appears tribasic with soluble blue. As the alkaline tribasic phosphates are readily decomposed by water the change takes place gradually towards the end. Disodic phosphate is alkaline to litmus and orangé 3, neutral to phenol-phthaleine and acid to soluble blue. Arsenic acid behaves like phosphoric acid. Phosphorous acid is monobasic with orangé 3 but bibasic with soluble blue and phenol-phthaleine. Hypophosphorous acid manifests only a bibasic biacid tendency. Carbonic acid is bibasic with soluble blue, so that, *e.g.*, potassium bicarbonate, which is alkaline to litmus and orangé 3, may be titrated in presence of soluble blue with a solution of potassa, like an acid. Salicylic acid is monobasic with all reagents, like lactic acid. With its isomers, the meta- and para-oxybenzoic acid, the case is different. Whilst salicylic acid does not show its phenol function with any reagent its isomer, para-oxybenzoic acid, is monobasic with litmus and bibasic with soluble blue.

Studies on Chlorophyll.—Victor Jodin.—The author finds experimentally that when the physiological integrity of a leaf is sacrificed the action of light upon it is merely destructive of chloryphyll and provocative of oxidation.

Justus Liebig's Annalen der Chemie, Vol. ccxxxi, Part 3.

Communications from the Chemical Laboratory of the University of Tübingen.—These include memoirs by H. Spindler on the exchange of chlorine, bromine, and iodine between organic and inorganic haloid compounds, by C. Kerez on the action of the haloid compounds of aluminium upon haloid-substituted hydrocarbons, and by E. Lellmann and C. Klotz upon dichlortoluoles and dichlorbenzoic acids.

The Action of Hydrogen Phosphide upon Solutions of Metallic Salts.—Paul Kulisch.—This action takes two directions. Either the metallic salts are reduced (cupric chloride to cuprous chloride, thallous oxide to metallic thallium, gold chloride to metallic gold, ferric chloride to ferrous chloride) or the hpdrogen phosphide is transformed with the metallic salts to metallic phosphides, as in the case of cuprous chloride and bismuth salts. In most cases both reactions take place simultaneously, so that we obtain mixtures of metals and metallic phosphides. This result is demonstrated in case of the solutions of copper sulphate, the ammoniacal copper solutions, and the salts of silver, cobalt, and nickel. In other cases (lead and cadmium) the composition of the precipitate indicates mixtures of free metal and of a phosphide, but these constituents have not been separated, nor, indeed, demonstrated with certainty. The phosphides obtained by passing hydrogen phosphide into metallic solutions are very readily oxidised, especially in a moist state. Their other properties fluctuate greatly. They are all decomposed by strong acids with the liberation of hydrogen phosphide of the kind not spontaneously inflammable. Cadmium phosphide, however, forms an exception. The action of hydrogen phosphide upon metallic salts is in general very slow, owing to its sparing solubility in water. In certain cases, *e.g.* thallium, the action becomes perceptible only in the course of some hours. The salts of silver form an exception.

On Terephthal-aldehyd.—W. Löw.—Terephthal-aldehyd behaves in general like a double benzaldehyd, but in certain cases, when in the substitution of one aldehyd group the new molecular structure acquires an especial firmness, the properties of the second aldehyd group do not come into play in their full extent. Instances are terephthal-aldehydic acid, aldehyd-cinnamic acid, and aldehyd-malachite green.

Bulletin de la Société Chimique de Paris.
Vol. xlv., No. 1, January, 5, 1886.

Action of Copper upon Aqueous Solutions of Sulphurous Acid.—M. Cause.—Copper belongs to the class of metals reputed as not decomposing water at the ordinary temperature in presence of acids. This decomposition, however, can be effected and copper found to behave like iron and zinc if nascent hydrogen can effect a secondary reaction such as a reduction. To prove this fact the author adds copper to an aqueous solution of sulphurous acid. After some time hydrogen sulphide is found to be present.

No. 2, January 20, 1886.

On Sodium and Potasssium Racemates, and on the Causes which determine the Splitting-up of certain Racemates.—G. Wyrouboff.—The author calls in question the hypothesis of M. Pasteur, that the racemates are split-up only under the influence of organic germs diffused in the atmosphere, and that such splitting-up ceases to take place if we operate in an atmosphere freed from organised beings. This hypothesis, the author holds, explains nothing. Why do these germs attack only a very limited number of the racemates? What is their mode of action? Why does their action cease at certain temperatures different for each salt? All the racemates except those of sodium and ammonium, of sodium and thallium, and of sodium and potassium, are less soluble at mean temperatures than the corresponding tartrates, and cannot therefore split-up. But it does not follow that their splitting-up is impossible at all temperatures. A racemate is not a simple mixture of the two tartrates: it has a distinct individuality, and it has always a different hydratation from that of the tartrates into which it splits up.

The Neutralisation of the Aromatic Acids.—M. Berthelot.—The author's thermic determinations relate to the mellic, meconic, and acrylolactic acids. The neutralisation-heat of true acidity oscillates about +13 cals. for the most varied organic acids.

Researches on Isomerism in the Aromatic Series. Neutralisation-Heat of the Oxybenzoic Acids.—MM. Berthelot and Werner.—Already mentioned.

On Isomerism in the Aromatic Series. On the Oxybenzoic Acids, and on their Formation- and Transformation-Heats.—MM. Berthelot and Werner.—The reciprocal transformation of isomers of the same chemical function gives rise only to feeble thermic effects, and consequently to a work relatively very small compared with that which corresponds to combinations, properly so called, to polymerisations, and to changes of real function.

Researches on Isomerism in the Aromatic Series. Action of Alkalies upon Phenols of a Mixed Function.—M. Berthelot.—The author's results show a perfect harmony between thermic indications and chemical theories relating to complex phenolic functions.

On Various Phenols.—M. Berthelot.—Alizarin in a very dilute solution only manifests towards the alkalies one of its two characteristic phenolic functions. It behaves in this respect like pyrocatechine, and like various simple phenols (pyrogallol and phloroglucine), or mixed (salicylic acid), of the ortho-series.

Pyrogenous Decomposition of the Acids of the Fatty Series.—M. Hanriot.—The author, after studying the succinic, adipic, glycolic, lactic, and pyruvic acids, finds that they are all split-up in a very simple manner with the loss of carbonic acid. Glycolic acid forms an exception, and the profound decomposition which it undergoes seems to depend on the elevated temperature of the reaction.

Continuous Preparation of Oxygen by means of Calcium Chloride and Cobalt Oxide.—A. Bidet.—The author has devised an apparatus for working out this process, a figure of which is given.

Detection of Acetone in Liquids, especially in certain Pathological Cases.—P. Chautard.—The author dissolves ¼ grm. of magenta in ½ litre of water, and passes into it a current of sulphurous acid. The liquid takes a very pale yellow colour, and may be preserved indefinitely in a stoppered bottle. To detect acetone in urine it is sufficient to pour into a test-tube, containing from 15 to 20 c.c. of the urine, 1 c.c. of the reagent above mentioned. If acetone is present a violet colouration is produced.

Action of Chlorine upon Anhydrous Chloral.—H. Gauttier.—In darkness there is no action, whilst in sunlight the contents of the flask or bottle are completely decolourised in two or three hours.

Moniteur Scientifique, Quesneville.
Vol. xvi., February, 1886.

Notes on the Literature of Explosives (concluded).—Prof. C. Munroe.—From the Chemical News.

Industrial Review.—This includes studies on the utilisation of the slags of the Thomas process; on the fixation of aniline colours by means of antimonious salts; and new methods of mordanting with chrome, and applying gallo cyanine in dyeing and printing.—All from the *Chemiker Zeitung*.

Chemical Patents taken Abroad.—We have here notices of Schroeter's patent for the preparation of ichthyol-sulphonic acid; Müller's process for preparing a firm grease, specially destined for lubricating machinery; Fahlberg and List's patent for obtaining ortho-sulphamine benzoic anhydride, called also "saccharine"; E. H. and A. H. Cowles' improvements in the reduction of ores and the preparation of alloys by the aid of electricity; process of preparing tin oxide and tin-crystals electrolytically, by

R. Tamine and E. de Cuyper; G. Link's process for purifying crude naphthaline by means of soaps; and Dahl's process for the preparation of sulphuretted naphthols and of azo colouring-matters.

The Fatty Matter and the Wax contained in Cinchona-Barks.—O. Hesse.—From Liebig's *Annalen*.

The Process of Tanning with Chrome.—W. J. A. Donald.—From the *Journal of the Society of Chemical Industry*.

Report on the International Exhibition of Inventions at London.—Watson Smith.—From the *Journ. Soc. Chem. Industry*.

Classification of the Colours derived from Coal-Tar.—W. R. Richardson.—From the *Journ. Soc. Dyers and Colourists*.

Summary of the Present State of Knowledge on the Artificial Colours used in the Arts.—Dr. E. Noelting.—The first portion of the first of a course of six lectures delivered at the School of Chemistry at Mulhouse. The matter here inserted extends merely to the history of the principal tar-colours, and to theoretical considerations on the constitution of benzol and its derivatives.

Patents connected with the Chemical Arts taken in France.—A list of titles of patents for November last.

Journal de Pharmacie et de Chemie.
Series 6, Vol. xiii., No. 2, January 15, 1886.

Phosphatic Urine, apparently Albuminous.—P. Carles.—The author refers to the fact that urine which is neutral, or but slightly acid, often gives on heating a coagulum which simulates that produced by albumen. A drop of acetic acid, however, causes this precipitate to disappear, whilst it has no effect upon coagulated albumen. He considers that the spurious precipitate is due to the presence of bibasic phosphates.

The Preparation of Galactose.—E. Bourquelot.—The author effects the process in closed vessels, at a temperature a little above 100°.

Examination of a Liquid of Ascites.—L. Grimbert.—The aspect of the liquid was that of milk. It was neutral to litmus-paper, and this neutrality continued unchanged for more than ten days. During this time no deposit of figured elements occurred, and no trace of fibrine coagulated. It had no odour. On microscopic examination there appeared merely a few fatty globules, very refractive and of small diameter. At 15° its sp. gr. was 1·008. Acetic acid produced no turbidity. Nitric acid and potassium ferrocyanide, mixed with acetic acid, gave very distinctly the reaction of albumenoids. An excess of hydrochloric acid gave in the cold a transparent liquid of a slight violet tint. Glycerin rendered it almost entirely clear.

On a New Method for taking the Fusion and Solidification Points of Neutral Fatty Bodies, and of their Acids.—M. Loviton.—The method consists in recording the magnified phenomena observed on submitting to the microscope a preparation made with the substance in question, and capable, without removal, of being made to vary in temperature at will.

On a Method of Disinfecting Sewer Openings.—E. Monin.—The author uses a disinfectant composed of permanganate or carbon, coal-tar or creosote, and iron sulphate. He remarks that the action of permanganate and of carbon is respectively different, permanganate being an oxidiser and carbon an absorbent or reducer.

The Question of Jequirity and of Jequiritic Ophthalmia.—A medical paper.

The Manna of Turkestan.—M. Markownikoff.—From the *Journal of the Chemical Society*, and the *Journ. Russ. Chem. Soc.*

On Buchu (Barosma crenata).—M. Spica.—From the *Journal of the Chemical Society*.

The Determination of Alkaloids in Extract of Belladonna.—H. Kunz.—Recent leaves of *Belladonna* contain 0·15 to 0·60 per cent of atropine, and the roots 0·30 to 0·60 per cent. The extract contains, according to German analyses, 1·3 to 1·6 per cent of atropine. Le Roy Weber finds 2·57 per cent in an extract according to the American Pharmacopœia. The author finds among the bases choline, which he had previously recognised in the flowers of the elder.

Asbestos Filters.—A. Couvert.—Asbestos paper is now met with in commerce, and is suitable for the filtration of almost all liquids.

The Reductive Action of Coke on Nitric Acid dissolved in Sulphuric Acid in Gay-Lussac's Tower.—G. Lunge.—At the temperature of 38° to 40°, which prevails in the Gay-Lussac towers, this action is very rapid, and the entire nitric acid is transformed into nitrous acid.

Determination of Sulphuric Acid in Vinegar.—B. Kohnstein.—The author saturates 100 c.c. of vinegar with magnesia, filters, and exposes the filtrate to a temperature of 25° to 30°. The organic salts are entirely transformed into carbonates, whilst magnesium sulphate remains unchanged. It is taken up with water saturated with carbonic acid, filtered, and the precipitate is washed. Magnesia is determined in the filtrate, and from it is deduced the quantity of free sulphuric acid contained in the vinegar.

Bulletin de la Société d'Encouragement pour l'Industrie Nationale. 3rd Série. Vol. xii., No. 143, Nov., 1885.

Report presented by M. Biver on behalf of the Committee of Chemical Arts, on M. Kolb's Appliances for raising Corrosive Liquids.—These apparatus, which cannot be explained without the aid of the accompanying diagrams, are divided into two classes, emulsifiers, in which the liquid to be raised is intimately mixed with bubbles of air, compressed or at its natural pressure. The other class includes pulsometers, actuated by compressed air instead of steam.

On Panary Fermentation.—Aimé Girard.—From the *Comptes Rendus*.

On Algin.—Watson Smith.—From the *Journal of the Society of Chemical Industry*.

New Process for detecting and determining Traces of Nitric Acid in Air, Water, Soils, &c.—MM. Grandval and Lajoux.—From the *Comptes Rendus*.

MISCELLANEOUS.

Tonbridge School.—New Science Buildings are now being erected for Tonbridge School, at a cost of nearly £14,000. They will be close to the present buildings, and will contain chemical and physical laboratories, lecture room, class rooms, preparation rooms, and, in addition, a library and room for drawing.

Thermometers for Extreme Temperatures (up to a White Heat).—These instruments, the invention of Messrs. Heisch and Folkard, are specially adapted for all purposes where the temperatures are beyond the range of the ordinary mercurial thermometer, and where an expensive pyrometer has been the only available instrument up to the present time. The reading is taken in exactly the same way as with an ordinary thermometer, the temperature being indicated by the pressure of the air enclosed in a bulb, which is exposed to the source of heat, acting on a vertical column of mercury. By employing a platinum or porcelain bulb the very highest temperatures can be indicated. One of the great advantages of the instru-

ment is that the temperatures are seen at a glance without the time and manipulation required in using the Siemens or other pyrometer. The instrument is, of course, unaffected by changes in the height of the barometer, being hermetically sealed.

The Standard Thermometer, for Chemical and Physical Laboratories, is a convenient form of the simple air thermometer used in physical research. The range of the instrument is from the lowest attainable temperatures up to the softening point of the bulb. The instrument, like the other, is hermetically sealed, and consequently unaffected by barometric variations. It consists of a bulb of platinum or porcelain connected to a glass tube bent back on itself twice, and at right angles to the axis of the bulb; one end of the bent tube is pivoted on the base of the instrument, leaving the other end free to move up and down on a vertical scale, describing an arc round the pivot; the vertical scale is made to move backwards and forwards on a horizontal rod, and can be fixed in any position by means of a set screw. By an easy adjustment, somewhat similar to that of Fortin's barometer, the pressure of the gas enclosed in a bulb exposed to the source of heat is measured in inches or millimetres on the divided scale. From the pressure thus measured the temperature can be at once deduced, either graphically on millimetre paper or by calculation. The pressure of the gas enclosed in the bulb is balanced by a column of mercury contained in the tube, the inclination of which can be varied. The resultant pressures are proportional to the sines of the angles of inclination of the mercurial column to the horizon, after allowing for capillarity; but, as stated above, these pressures are in practice read off on the graduated brass scale. An observation occupies about one minute, the manipulation being as follows:—Level the base plate of the instrument, the bulb being exposed to the temperature to be measured and the mercury tube being horizontal or nearly so. Raise the mercury tube slowly by means of the sliding roller carriage on the brass scale, at the same time moving the scale along the horizontal brass rod as required, and gently tap the mercury tube. The column of mercury will descend in the tube, leaving a vacuum in the upper part. This raising of the tube is to be continued (tapping gently each time) until the top of the mercury is level with a standard mark on the tube. The gas in the bulb is now compressed to a definite volume by the inclined column of mercury, the vertical height of which represents the pressure. To graduate a new bulb or verify an old one, immerse the bulb in melting ice, or in the steam of boiling water, as may be most convenient, and read off on the brass scale the *vertical* height of the column of mercury required to compress the gas to the definite volume (*i.e.*, to the mark on the mercury tube) at 0° or 100° C., as the case may be. For example:—

Vertical height of top of mercurial column at 100° C.	7·53 inches.
Vertical height of bottom of mercurial column at 100° C.	0·58 ,,
Pressure of gas in bulb at 100° C.	6·95 ,,

Suppose now we wish to take the temperature of the vapour of boiling sulphuric acid. Observe the pressure in the same way as before, thus:—

Vertical height of top of mercurial column	11·73 inches.
Vertical height of bottom of mercurial column	0·63 ,,
Pressure of gas in bulb	11·10 ,,

A simple calculation gives the temperature.

6·95 inches pressure = 100° C. What is the temperature at 11·10 inches?

$695x = (1110 \times 375) - (695 \times 375)$.

$\therefore 695x = 416{,}250 - 260{,}625 = 155{,}625 \therefore x = 224°$.

A much simpler plan of deducing the temperature from the pressure is by construction on millimetre paper, for by calculating out two extreme temperatures (the ordinates representing the pressures and the abscissæ the number of degrees) and joining the tops of the two ordinates by a straight line, all the intermediate temperatures can be measured off in the ordinary way.

NOTES AND QUERIES.

*** Our Notes and Queries column was opened for the purpose of giving and obtaining information likely to be of use to our readers generally. We cannot undertake to let this column be the means of transmitting merely private information, or such trade notices as should legitimately come in the advertising columns.

Compressor Engine.—Can any of your readers inform me what kind of engine would be found most suitable for compressing the acid gases from pyrites kilns, the gases being previously cooled; also the address of makers?—W.

MEETINGS FOR THE WEEK.

MONDAY, 22nd.—London Institution, 5.
— Medical, 8.30.
— Society of Arts, 8. (Cantor Lectures). "Science Teaching," by Prof. F. Guthrie, F.R.S.
TUESDAY, 23rd.—Institution of Civil Engineers, 8.
— Royal Medical and Chirurgical, 8.30.
— Royal Institution, 3. "The Unexhibited Portion of the Greek and Roman Sculptures in the British Museum," by C. T. Newton, C.B.
WEDNESDAY, 24th.—Society of Arts, 8. "The Employment of Autographic Records in Testing Materials," by Prof. W. C. Unwin.
— Geological, 8.
THURSDAY, 25th.—Royal, 4.30.
— London Institution 7.
— Royal Institution, 3. "The Ancient Geography of Britain, by Prof. W. Boyd Dawkins, F.R.S.
— Society of Arts, 8. "Photography and the Spectroscope in their Applications to Chemical Analysis," by Prof. W. N. Hartley, F.R.S.
FRIDAY, 26th.—Royal Institution, 9. "Photography as an Aid to Astronomy," by A. A. Common, F.R.S.
— Quekett Club, 8.
SATURDAY, 27th.—Royal Institution, 3. "The History of Geometry," by Rev. C. Taylor.
— Physical, 3. "Notes on the Thermo-dynamic Relations in the Paper of Messrs. Ramsay and Young," by Prof. W. C. Unwin. "On a Map of the World in which the Proportion of Areas is Preserved," by Walter Baily.

Just published, price One Shilling.

A CATALOGUE of CHEMICAL PERIODICALS. By H. CARRINGTON BOLTON, Ph.D., Professor of Chemistry in Trinity College, Hartford, Conn. First published in the *Annals of the New York Academy of Sciences*, and Reprinted from the *Chemical News*.

London: *Chemical News* Office, Boy Court, Ludgate Hill, E.C.

Silicates of Soda and Potash in the state of Soluble Glass, or in CONCENTRATED SOLUTION of first quality, suited for the Manufacture of Soap and other purposes, supplied on best terms by W. GOSSAGE and Sons, Soap Works, Widnes, Lancashire

London Agents, COSTE and Co., 19 and 20, Water Lane, Tower Street E.C., who hold stock ready for delivery.

THE CHEMICAL NEWS.

Vol. LIII. No. 1370.

ANALYSIS OF EMBOLITE FROM ST. ARNAUD, VICTORIA.

By J. M. H. MUNRO, D.Sc., F.C.S.

There do not appear to be many published analyses of this mineral, although according to Mr. Field (quoted by Dr. Percy) much of the reputed silver chloride consists really of chlorobromide. The six analyses given by Dr. Percy ("Metallurgy of Silver and Gold," Part I., p. 217) were all made by Mr. Field, and refer to specimens from one locality—the Chañarcillo Mine, Chile. These analyses agree with one or other of the three formulæ, 2AgCl,AgBr; 3AgCl,2AgBr; AgCl,3AgBr.

Another locality for this mineral is St. Arnaud, Victoria, and an analysis of embolite from this district, by Mr. Charles Wood, is quoted by Brough Smyth in his "Gold Fields of Victoria," p. 411. This analysis shows the embolite from this locality to have a more simple formula than those given above, and agrees exactly with the numbers required for AgCl,AgBr, viz., silver 65·16, bromine 24·16, chlorine 10·71—100·00.

A specimen of mice-eaten ferruginous quartz, dotted over with minute grains of embolite, was brought home from St. Arnaud by my father, Mr. J. M. Munro, and analysed by him. It was obtained above water-level in what is locally known as the "Rotten Reef," and the quartz was so extremely friable and so decomposed, that, although the embolite was abundantly disseminated throughout, it required some hours' patient work with a needle and a lens to detach sufficient of the soft irregular-shaped nodules of mineral for analysis: 5·431 grains of nearly clean mineral obtained in this way were reduced with zinc and sulphuric acid, and the reduced silver dissolved in nitric acid and weighed as chloride, the chlorine and bromine of the mineral being precipitated from the zinc solution by silver nitrate, and weighed together as silver chloride and bromide; 4·563 grains pure silver chloride were obtained, and 5·329 grains mixed silver chloride and bromide. Hence the 5·431 grains mineral contained 0·102 grain gangue, confirmed by an actual weighing of the insoluble residue. From these figures we get the following calculated composition for the pure mineral.

Silver	64·45
Bromine	25·84
Chlorine	9·70
	99·99

These numbers agree substantially with the formula AgCl,AgBr, given by Mr. Wood.

College of Agriculture, Downton, Salisbury.

ON THE RAPID ESTIMATION OF MAGNESIA AS AMMONIO-MAGNESIC PHOSPHATE.

By LAWRENCE BRIANT. F.C.S.

The estimation of magnesia by precipitation with sodic phosphate in the presence of an excess of sodic hydrate is a tedious process, on account of the length of time required to ensure complete precipitation,—variously stated as twelve to twenty-four hours. Experiments were conducted to determine whether the well-known accelerative action of agitation could not be applied to this process, and thereby shorten the duration of the experiment.

The mode of procedure was as follows:—Comparative determinations were made in which the quantity of magnesia in given solutions was estimated by three ways. First, precipitation in the ordinary manner, allowing the liquid to stand in the cold for twenty-four hours; second, after twelve hours; and third, after violently shaking in a stoppered glass jar for ten minutes, at once throwing the liquid on to a filter. The volume of liquid was in each experiment the same, viz. 115 c.c., whilst the precipitate was washed with 100 c.c. of dilute ammonic hydrate (1 to 3), divided into three different washings, between each of which the filter was allowed to drain completely. The precipitate in the case of the experiments in which the liquid was violently shaken was very granular, and was without difficulty completely transferred to the filter.

The results are as follows:—

Treatment.	MgO found.	MgO present.
	Grm.	Grm.
1. Stood 24 hours ..	0·050	0·050
2. Stood 12 hours ..	0·049	0·050
3. Shook 10 minutes..	0·051	0·050
4. Ditto ditto ..	0·050	0·050
5. Ditto ditto ..	0·050	0·050
6. Stood 24 hours ..	0·022	0·022
7. Stood 12 hours ..	0·022	0·022
8. Shook 10 minutes..	0·021	0·022
9. Ditto ditto ..	0·020	0·022
10. Stood 24 hours ..	0·002	0·002
11. Stood 12 hours ..	0·003	0·002
12. Shook 10 minutes..	0·002	0·002
13. Ditto ditto ..	0·0017	0·0015

These experiments seem to prove that whilst the method recommended vastly shortens the length of time occupied in making a determination of magnesia, it in no wise impairs its accuracy.

NOTE ON SO-CALLED "PANCLASTITE."

By H. SPRENGEL, Dr. phil., F.R.S.

In "Notice sur la Panclastite, &c., '*par*' Eugène Turpin, Paris, E. Bernard and Cie., 1882," we read:—

P. 11.—"Panclastite. (Brise tout;—de: παν, tout; κλαω, je brise.) *Explosifs à base de peroxyde d'azote.*

"Principe découvert par Eug. Turpin (1878 à 1882).

"Le corps comburant est le peroxyde d'azote pur et anhydre à l'état liquide.

"Cette section a cela de tout à fait remarquable, c'est qu'aucun des produits qui entrent dans la composition des nombreux explosifs qui en font partie n'a jamais été employé à la confection d'un autre mélange détonant. Le comburant ou les combustibles n'ont jamais été appliqués, en aucun cas, dans ce but, soit ensemble, soit séparément, tandis que dans les 1re, 2e et 4e sections on retrouve le soufre et le charbon.

"Recherchant de suite toute ce que pouvait lui donner la découverte de ce nouveau principe, M. Turpin est parvenu à produire plus de cent explosifs nouveaux, c'est-à-dire un nombre plus considérable que celui qui comprend tous les explosifs connus antérieurement."

P. 5.—"La *Panclastite* est dans ce dernier cas. Découverte par M. Eugène Turpin, elle constitue une invention de principe qu'il ne faut pas confondre avec une invention reposant sur des principes connus, ce qui est le cas de la dynamite; les inventions de principe sont extrêmement rares et tendent à diminuer encore au fur et à mesure que le progrès se développe, tandis que les inventions d'application ou de perfectionnement augmentent constamment."

On this "invention de principe" Sir Frederick Abel in his Presidential Address at the annual meeting of the Society of Chemical Industry, July 11, 1883 (vol. ii., p. 313), kindly expresses himself thus:—

"Sprengel urged that the facts brought forward by him were susceptible of important application, because powerful explosive cartridges or charges might at any time be rapidly prepared from two ingredients which, kept separately, are non-explosive. The suggestion to deal, in mining or military operations, with highly corrosive and more or less volatile liquids, upon the extensive scale which would be necessary if Sprengel's system were turned to practical account, has not commended itself to those experienced in such matters, but attention has quite recently been directed to the subject by a M. Eugène Turpin, who puts forward as an invention of his own what he calls a new series of explosives, which he has christened 'Panclastite,' but which are actually Sprengel's explosive mixtures. In his memoir of 1873 Sprengel gives a table of the total percentages of oxygen, and the percentages of available oxygen, in a great number of oxidising agents, and the superiority of monohydrate of nitric acid over the majority in the latter respect is there shown. Turpin uses, or says he uses, anhydrous nitrogen peroxide as the oxidising agent in his Panclastite series, together with carbon bisulphide or nitro-products of hydrocarbons. He therefore carries out Sprengel's suggestions, selecting for the purpose an oxidising agent of comparatively costly and inconvenient nature, and certainly not superior in oxidising power to the strongest commercial nitric acid. The publication in France of researches or inventions as original, the results or description of which have long been published in England, is an occurrence to which we are not unaccustomed, and so the performances of Sprengel's offspring, furnished by M. Turpin with an impressive family name, are exhibited at Chatou-Rueil, near Saint-Germain, with much flourish of trumpets, and have recently been officially reported upon by a Royal Engineer officer as marvels of novelty and of explosive power."

Though it may appear to be somewhat late to refer at this time to the foregoing comments on my paper in the *Journal of the Chemical Society* of August, 1873, I hope that the importance which this matter promises to attain will excuse and justify the following Note:—

The "beau idéal" of a detonating explosive is a mixture of 8 parts (88·9 per cent) of liquid oxygen and 1 part (11·1 per cent) of liquid hydrogen.

In my paper of 1873 I say, page 799:—"On referring to the foregoing table the reader will be reminded that peroxide of hydrogen is the highest oxygen compound known, while nitric anhydride is the compound which contains the largest amount of oxygen available for combustion (74 per cent). But as this compound, as well as the next two, nitric peroxide (69·5 per cent oxygen) and tetranitromethane (65·3 per cent oxygen) are: at present: on account of their nature and their difficult preparation, mere chemical curiosities, my attention naturally turned to the fourth, to *nitric acid* (63·5 per cent oxygen), which is a cheap and common article of commerce."

Now, when Mr. Turpin's attention turned to the second oxidiser on my list—to nitric peroxide—he found that this substance does *not corrode* metals, such as iron, copper, and tin under 356° F. (180° C.); and further, that combustible liquids, such as petroleum, carbon bisulphide, and nitro-benzene are readily soluble in nitric peroxide *without* rise of temperature. These are valuable properties, *first noticed by Mr. Turpin.*

What was formerly a chemical curiosity, is now an article of commerce. Nitric peroxide may be bought today at eighteen pence the pound, and I see ways and means of producing it a great deal more cheaply. Nitric peroxide is a yellowish liquid, heavier than water (sp. gr. = 1·451) and boils at 71° F. (22° C.), but may be kept like ether or similar volatile liquids. In France it is sent about in tinned-iron cans.

Taking as a typical example a benzene-mixture

$$C_6H_6 = 18{\cdot}4 = \left.\begin{matrix}17{\cdot}0\ C\\ 1{\cdot}4\ H\end{matrix}\right\} = \begin{matrix}62{\cdot}6\ CO_2\\ 12{\cdot}6\ H_2O\end{matrix}$$

$$7\tfrac{1}{2}(NO_2) = \frac{81{\cdot}6}{100{\cdot}0} = \left.\begin{matrix}56{\cdot}8\ O\\ 24{\cdot}8\ N\end{matrix}\right\}$$

we see, that the 18·4 parts of benzene require 56·8 parts of oxygen for the oxidation of their carbon and hydrogen to carbonic acid and water. This oxidation or combustion takes place at the moment of explosion at the expense of the 56·8 parts of oxygen, contained in the rest of the mixture—the 81·6 parts of nitric peroxide. No other explosive now in use (including blasting gelatin) contains weight for weight a greater amount of combustible matter, and as an explosion of *these* bodies is simply a sudden combustion, I again beg to draw attention to the fact, that the oxygen available for combustion in gun-cotton is most probably not more than 32·3 per cent and in nitroglycerin 42·3 per cent,* while in this case we have without a doubt 56·8 per cent. Hence no other explosive now in use can rival this and similar mixtures in power, as I published in 1873. They still remain *the most powerful* explosives known.

It hardly need be said, that an explosive of this nature consists of two parts—an oxidising and a combustible agent—and that Mr. Turpin with the same naïveté lays claim not only to the first but also to the latter half of the subject.

None of my *safety*-explosives are licensed in England, though many of them, when mixed, are much less sensitive to concussion than common gunpowder.

In April 1884 the French military authorities were busy near Rochefort with shells of the "système Turpin." These shells, so my informant said, were made of such a size and possessed such a prodigious power, that a ship struck by one of them would inevitably be sent to the bottom of the sea, even were she the strongest ironclad afloat. It is devoutly to be hoped that those whose office it is to provide for the defence of the British Navy *will be ready* in the hour of need to serve out shells, filled with an explosive of equal force or better still with something superior, approaching more closely the "beau idéal."

CONTRIBUTIONS TO THE KNOWLEDGE OF SAMARIUM.†

By P. T. CLEVE.

(Concluded from p. 93).

Chromate of Samarium and Potassium, $SmK_2CrO_4 + 3H_2O$.

A SOLUTION of bichromate of potassium is not precipitated by nitrate of samarium, but a solution of the neutral chromate is. A bulky yellow precipitate is thrown down, which soon settles down as a crystalline powder of the double salt. As it is decomposed by washing with water it was taken from the filter and freed from the solution by pressure only. The salt of samarium was in excess.

1·6367 grm. lost by 100° 0·0880 grm., and on heating nearly to redness a further loss of 0·0165 grm., or in all 0·1045 grm. H_2O. On dissolving in nitric acid and

* Of these, by the by, only 38·8 per cent can be utilised for want of fuel, as pointed out by me in my patent of 1871 and verified four years later by the force of Nobel's blasting gelatin, in which the excess of 3·52 per cent oxygen is utilised by the dissolved gun-cotton, an explosive too rich in carbon. See: Abbot's table, p. 17, in "The Hell-Gate Explosion near New York and so-called 'Rackarock,' with a few words on so-called 'Panc astite,'" by H. Sprengel. London: E. and F. N. Spon, 1886.

† Presented to the Royal Society of Sciences of Upsala, Feb. 13, 1885.

precipitating with mercurous nitrate a precipitate was obtained which yielded on ignition 0·5387 grm. Cr_2O_3. From the filtrate, freed by H_2S from mercury, 0·6415 grm. Sm_2O_3 was thrown down with ammonia. The filtrate from the samarium hydroxide gave 0·3335 grm. K_2SO_4.

Acetate of Samarium, $Sm_3C_2H_3O_2 + 4H_2O$.

This salt crystallises at ordinary temperature on spontaneous evaporation in short prisms or tabular crystals which are moderately soluble in water. On evaporating the concentrated solution on the water-bath needle-shaped crystals containing less water are obtained, but the exact quantity of the water of crystallisation in the salt could not be determined, as the salt very rapidly takes up water from the mother-liquor.

The salt crystallised at the ordinary temperature gave on analysis:—

0·7886 grm. lost at 110° 0·1393 grm. H_2O and gave by ignition 0·3444 grm. Sm_2O_3.

0·8688 grm. lost 0·1546 grm. H_2O and gave 0·3802 grm. Sm_2O_3.

Ethylsulphate of Samarium, $Sm_3C_2H_5,SO_4 + 9H_2O$.

The solution obtained by double decomposition of the sulphate of samarium with ethylsulphate of barium deposits, on evaporating it slowly over oil of vitriol, large pale yellow and well-formed crystals which are easily soluble in water. Heated to 100° to 110° the salt is decomposed. The loss, 34 per cent, corresponds to 3 mols. C_2H_5OH and $5H_2O$ (33·2 per cent).

0·4253 grm. gave 0·1809 grm. Sm_23SO_4.

Oxalate of Samarium, $Sm_23C_2O_4 + 10H_2O$.

On adding a solution of oxalic acid to solutions of the salts of samarium bulky white and gaseous precipitates are thrown down which soon become heavy and crystalline. Oxalate of samarium is soluble in concentrated nitric acid. At 110° it loses $6H_2O$.

1·0029 grm. gave by ignition 0·4638 grm. Sm_2O_3.

In per cent, 46·25 Sm_2O_3; calc. 46·77.

Oxalate of Samarium and Potassium, $KSm2C_2O_4 + 2(\frac{1}{2}?)H_2O$.

A solution of the nitrate of samarium gave with an excess of neutral oxalate of potassium a white amorphous precipitate. Only a very small quantity remained in the solution. The salt was simply pressed between filter-paper and then analysed.

0·7401 grm. lost 0·0721 grm. H_2O at 125° and at 190° an additional 0·0085 grm., or total 0·0806 grm. H_2O. From the same quantity 0·3063 grm. Sm_2O_3 and 0·1345 grm. KCl were obtained.

In per cent—

		Calculated.	
Sm_2O_3	41·39	174·0	42·43
K_2O..	11·47	47·1	11·48
C_2O_3	—	144·0	—
H_2O..	10·89	45·0	10·97
		410·1	

It is to be assumed that a part of the water found consisted of only hygroscopic moisture, so that the amount of water given in the above formula must not by any means be regarded as exact.

Succinate of Samarium,

$Sm_2C_2H_4(CO_2)_2 + 5H_2O$ (at 100° dried $3H_2O$).

On adding a solution of succinic acid to a solution of the acetate of samarium no precipitate is formed at the ordinary temperature, but, on warming, a copious white micro-crystalline powder is thrown down. The succinate is very sparingly soluble in water. It is decomposed on heating, and leaves a very voluminous oxide of samarium. The salt loses at 100° 5·87 per cent, corresponding to 2 mols. H_2O (calc. 4·88).

0·4333 grm. salt, dried at 100° gave on ignition 0·2161 grm. Sm_2O_3.

In per cent, 49·87 Sm_2O_3. Calculated from the formula with $3H_2O$: 49·57.

Tartrate of Samarium,

$Sm_2C_2H_2(OH_2)_2 + 6$ (dried at 100° 2) H_2O.

A solution of tartaric acid gives with acetate of samarium a white bulky precipitate, which, on warming, changes into a heavy granular non-crystalline powder. Very little samarium remains in the solution. The tartrate, when recently prepared, is soluble in caustic ammonia, but the solution deposits after some time, or immediately on boiling, a white powder. The salt pressed between filter-paper lost at 100° 8·67 per cent H_2O or 4 mols. (calc. 8·45).

0·4602 grm. salt dried at 100° gave on ignition 0·2067 grm. Sm_2O_3.

In per cent, 44·92 Sm_2O_3, and the formula with $2H_2O$ requires 44 61 per cent Sm_2O_3.

Citrate of Samarium,

$SmC_3H_4(OH)(CO_2)_3 + 6$ (at 100° dried 1) H_2O.

Citric acid gives with acetate of samarium a white, bulky, not crystalline precipitate. The salt is soluble in ammonia, and the solution remains clear on boiling.

The salt pressed between filter-paper lost on heating to 100° 21·48 per cent water, corresponding to 5 mols. H_2O (calc 20·13).

0·3828 grm. salt, dried at 100°, gave by ignition 0·1877 grm. Sm_2O_3.

In per cent, 49·03. The formula with $1H_2O$ requires 48·74 per cent.

Picrate of Samarium, $Sm_3C_6H_2(NO_2)_3O + 8H_2O$.

A solution of picric acid dissolves the oxide of samarium on boiling. The intensely yellow solution yields after concentration a heavy orange-coloured oil, which on further evaporation over oil of vitriol dissolves. Later on the salt crystallises in small yellow needles, which are easily soluble and melt below 100°. When strongly heated the salt explodes. The salt loses at 100° 11·83 per cent H_2O, or 6 mols. H_2O, calc. 11·04.

0·7312 grm. of the crystallised salt was dissolved in water and precipitated with an alcoholic solution of oxalic acid. On ignition 0·1308 grm. Sm_2O_3 was obtained.

In per cent, 17·89 Sm_2O_3, calc. 17·79.

Specific gravity—

0·6538 grm., temp. 18°.5, sp. gr. 1·954.

Destructive Distillation of Coal-Tar.—Professor Mills has enlarged and revised his "manualette" of the Destructive Distillation of Coal-Tar, Petroleum, Rosin, Oil, &c., and the new edition, with some illustrations of shale retorts, will be published next month by Mr. Van Voorst.

THIRD REPORT OF THE COMMITTEE*

RE-APPOINTED FOR THE PURPOSE OF DRAWING UP A STATEMENT OF THE

VARIETIES OF CHEMICAL NAMES WHICH HAVE COME INTO USE,

FOR INDICATING THE CAUSES WHICH HAVE LED TO THEIR ADOPTION, AND FOR CONSIDERING WHAT CAN BE DONE TO BRING ABOUT SOME CONVERGENCE OF THE VIEWS ON CHEMICAL NOMENCLATURE OBTAINING AMONG ENGLISH AND FOREIGN CHEMISTS.†

An account of the authorship of some of the various systems of nomenclature which have been devised for the purpose of distinguishing between compounds formed by the union of the same elements in different proportions, has been given in the "Historical Notes" prefixed to the Second Report of this Committee. Among these systems the use of the terminations *ous* and *ic*, to denote respectively lower or higher degrees of saturation of one element or group with another element or group, is perhaps that which has met with the widest acceptance. This system further directs that when electro-negative groups, the names of which ends in *ous* and *ic*, unite with electro-positive groups to form salts, these terminations are to be changed into *ite* and *ate* respectively.

Before proceeding to discuss the practical application of this system, it may be well to point out, as a minor etymological detail, that the literal meaning of the terminations *ous* and *ic* has altered since they were first employed. Thus *ous* (Latin *osus*) ought to denote, on the part of the compound, *richness in* that element to the name of which the termination is attached. For example, *cuprous* (*cuprosus*) means "rich in copper": *cuprous* oxide is primarily an oxide which is *richer in copper* than *cupric* oxide, and only by implication an oxide which is *poorer in oxygen*. This implied signification is, however, that in which the name *cuprous oxide* is nowadays employed. A curious result of this change of literal meaning is to be found in the use of the prefix *hypo* to denote a still lower degree of saturation than that expressed by *ous*. Thus the name *hyponitrous acid* is taken to denote an acid containing still less oxygen than nitrous acid; whereas *hyponitrous* really means "less rich in nitrogen," which is the very opposite. Had the etymology been logically carried out, the prefix ought to have been *hyper*. A similar confusion of ideas is displayed in the use of the prefixes *hyper* and *per* at the other end of the scale; in place of these, *hypo* ought to have been employed. *Perchromic acid* does not, as its name literally taken signifies, contain more chromium than *chromic acid*: it contains less, and ought consequently to have been termed *hypo*-chromic acid.

It need hardly be said that it would be ill-advised to attempt to change a system so firmly established as that involved in the present use of these prefixes *hypo* and *hyper*; and in the above remarks on the etymology of the subject, nothing of the kind is intended. No ambiguity can arise from the use of terms about the meaning of which everyone is agreed, and their mere etymological accuracy is, in view of this all-important consideration, of secondary importance.

The appended list (see next column) will show the application of the *ic* and *ous* nomenclature to salts and salifiable oxides.

Names corresponding with *platinous* and *platinic* would be applied to the corresponding oxides and salts of the other metals of the platinum group—distinguishing, however, the other oxides and salts of this group by numeral or other designations.

---

* Consisting of Professors Williamson, Dewar, Frankland, Crum Brown, Odling, and Armstrong, Drs. Hugo Müller, F. R. Japp, and H. Forster Morley, and Messrs. A. G. Vernon Harcourt, C. E. Groves, J. Millar Thomson, H. B. Dixon (Secretary), and V. H. Veley.

† Read at the British Association, Aberdeen Meeting, Section B.

I. *List of Salts where Two or more Series of Compounds are formed.**

Name denoting metallic radical of salt.	Formula of corresponding oxide.	Name denoting metallic radical of salt.	Formula of corresponding oxide.
Cuprous	Cu_2O	Chromous	CrO
Cupric	CuO	Chromic	Cr_2O_3
Mercurous	Hg_2O	Uranous	UO_2
Mercuric	HgO	Uranic (Uranylic)	UO_3
Aurous	Au_2O	Manganous	MnO
Auric	Au_2O_3	Manganic	Mn_2O_3
Thallous	Tl_2O	Ferrous	FeO
Thallic	Tl_2O_3	Ferric	Fe_2O_3
Stannous	SnO	Cobaltous	CoO
Stannic	SnO_2	Cobaltic	Co_2O_3
Cerous	Ce_2O_3	Platinous	PtO
Ceric	CeO_2	Platinic	PtO_2

The designations given in this Table to the various higher and lower series of salts and salifiable oxides have been employed with almost complete uniformity by all chemists who have adopted this system of nomenclature.

As a metal rarely—if ever—forms more than two salifiable oxides, the *ous* and *ic* terminations generally suffice for purposes of distinction so far as the salts of metals are concerned.

The practice of further employing these terminations in the case of acid-forming oxides does not lead to confusion, since these oxides are distinguished by the name *anhydride* (or *acid*). Thus we have—

CrO	Cr_2O_3	CrO_3
Chromous oxide.	Chromic oxide.	Chromic anhydride. (Chromic acid.)

Indifferent oxides have frequently been classified and named by regarding them as compounds of salifiable, with acid-forming oxides, Cr_2O_4 being termed *chromic chromate*. For stages lower than *ous*, the prefixes *hypo* and *sub* are employed. Custom appears to have restricted *hypo* chiefly to acids and to acid-forming oxides, *sub* to salifiable and to indifferent oxides.

With regard to the termination *ous*, the minor question arises, how far this termination ought to be written in the forms *ious* and *eous*. The answer is: as seldom as possible. "Cupreous" has generally given way to "cuprous"; no one writes "chromious" (although the name of the metal is "chromium"): and there is no reason why such names as "ruthenious" and "iridious" should not equally be shorn of their superfluous penultimate syllable.

A further question; concerning which considerable difference of opinion has prevailed, is whether any *ous* or *ic* terminations ought to be employed in the names of salts of which only one class is known—thus *magnesic sulphate* instead of *magnesium sulphate*. There is something to be said here for both systems; and, as the diversity of practice does not lead to confusion and consequently does but little harm (beyond in each case offending the ears of those accustomed to the opposite system), the question need not be regarded as a vital one. Objections which have been urged against the use of any termination in such cases are that chemists have not always been able to agree as to which termination is to be used in a given case, and that, apart from this, the practice causes beginners erroneously to surmise the existence of a second series of salts. The objection on the other side is that the omission of the terminal "ic" breaks the uniformity of the system and leads beginners to suppose that barium sulphate, for instance, has a different constitution from cupric sulphate. In the case of carbon compounds, on the other hand, there is a distinct advantage in affixing *ic* to the names of the positive radicals in ethereal salts. A neglect of this precaution leads to ambiguity—at all events in the *spoken* name. Thus, though there is no ambiguity in the name *ethyl phenylacetate* when written, yet the ear cannot distinguish between it and *ethylphenyl acetate*. This ambiguity is obviated by the use of the termination *ic*; thus, *ethylic phenylacetate* and *ethylphenylic acetate*.

In the use of the terminations *ous* and *ic* to distinguish different series of *acids and acid-forming oxides*, the practice of chemists has also been very uniform. Indeed, with the exception of one or two isolated cases almost perfect unanimity has prevailed.

To sum up, the *ous* and *ic* terminations when employed for purposes of distinction in cases where two series of oxides, acids salts, &c., are known, have been almost free from ambiguity, and for this reason deserve to be retained. On the other hand, in cases where only one series is known, those chemists who have employed one or other of these terminations have occasionally differed as to which ought to be used: the difficulty may be solved, as it has been done by some chemists, by avoiding the use of any termination in such cases.

In complex cases where the above modes of naming prove inadequate, recourse may be had to numeral designations. These appear especially admissible in cases where an oxide occurs which is intermediate between the *ous* and *ic* stage, and at the same time cannot be classed as a compound of oxides already classified and named.

In applying numeral designations it is most important to select only such as are free from hypothesis, and which afford correct information. In this respect chemists appear not to have been sufficiently careful of late years. As an example *arsenious oxide* may be quoted: this compound is frequently termed "arsenic trioxide," the formula being written As_2O_3, and it is tacitly assumed that the molecule contains three oxygen atoms. There are three objections to this name:—(1) That, assuming the formula on which it is based to be correct, it affords no information as to the number of *arsenic* atoms associated with the *three* oxygen atoms; (2) that it involves the assumption that arsenious oxide does not vary in molecular weight, whatever its physical state; and (3) that the formula of *gaseous* arsenious oxide is As_4O_6.

In employing numeral designations to indicate molecular composition in cases where this is established, it is therefore important to express the number of atoms of each constituent element, as *dicarbon hexachloride*, C_2Cl_6. But in the case of solid and liquid bodies of which the molecular weight is unknown, or which may vary with temperature, the name should merely indicate the relative proportions in which the constituents are associated; or, more explicitly, the name should indicate the proportion of the radical associated with what may be termed the characteristic element of the compound. No difficulty occurs in the case of the chloride, or analogous compound, of the monad elements generally, these being termed mono-, di-, tri-, tetra-, penta-, or hexa-chloride, &c., according as combination is in the proportion of 1, 2, 3, 4, 5, or 6 atoms of chlorine to 1 atom of the characteristic element. The application of this system would involve the use of the names tin dichloride and iron trichloride (not sesquichloride) for stannous and ferric chlorides respectively, names which accurately express the relative proportions of metal and of chlorine in these compounds without any hypothesis as to their molecular composition, which in the case of the former compound, at all events, certainly depends on temperature. It will, however, involve a slight departure from the existing practice when applied to oxides, sulphides, and other compounds of polyad elements; thus oxides of the type $(R_2)^{vi}O$ would be termed *hemi*-oxides, since they consist of the characteristic element and oxygen in the proportion of *one* atom of the former to *half* an atom of the latter. Oxides of the type $(R_2)^{vi}O_3$ would be termed *sesqui*-oxides, since the characteristic element and oxygen are present in the proportion of *one* of the former to *one and a half* of the

* In this list the term "salt" is taken to include "haloid salts," but to exclude the halogen compounds of those elements whose oxides do not yield oxy-salts with acids.

latter. Oxides of the type R_2O_5 would be termed *sesterti*-oxides, as they contain oxygen and the characteristic element in the proportion of *two and a half* atoms of the former to *one* of the latter. Oxides of the types RO, RO_2, RO_3, and RO_4 would be termed respectively *mono*-, *di*-, *tri*-, and *tetr*-oxides.

Acid Salts.

There are two distinct classes of salts to which this name has been given:—

1. Salts with two or more metals, one of the metals being hydrogen.
2. Salts formed from these by the removal of water.

Until comparatively lately no attempt was made to give distinctive names to these two classes, except that sometimes the words hydratic and anhydrous were used to distinguish them. The distinctive names—pyrophosphate, metaphosphate—which Graham gave to the two sets of anhydrous acid phosphates were founded on the supposition that the phosphoric acid (PO_5) existed in them in two modifications, different from the acid of the ordinary phosphates.

The nomenclature used by nearly all chemists from the beginning of this century until about 1860 is illustrated on Tables III. to VI. Acid salts in which for the same quantity of base there is two, three, . . . &c., times as much acid as there is in the normal salt are called bi——ate, ter——ate, &c. (in German, doppelt or zweifach ——saures Salz, dreifach——saures Salz, &c.). In English and French the Latin adverbial numerals *bis* or *bi*, *ter*, &c., seem always to have been used until about twenty years ago, when Greek adverbial numerals were introduced for the anhydrous acid salts. "Watts's Dictionary" and Naquet are the first English and French authorities in which we have observed this change.

Basic Salts.

There are two distinct classes of salts to which this name has been given:—

1. Salts with two or more salt radicals, one of the salt radicals being hydroxyl.
2. Salts formed from these by the removal of water.

These were not distinguished by name until quite recently, and are still very often confused.

The nomenclature in general use is illustrated on Tables 8 to 12.

Basic salts of oxygen acids in which for the same quantity of base there is ½, ⅓, &c., as much acid as there is in the normal salt are called di——ate, tri (or tris)——ate, &c. (in German, halb——saures Salz, drittel——saures Salz, &c.).

Basic salts of oxygen acid were also named by the proportion of base to acid, the proportion in the normal salt being taken as unity—bibasic, terbasic, &c., salts (in German. zweifach, dreifach, &c., basische Salze). Thus *tris*nitrate (drittel saures salpetersaures Salz) is the same as *ter*basic nitrate (dreifach basisches salpeter saures Salz), Latin adverbial numerals being used for multiples, and Greek adverbial numerals for submultiples.

The compounds of basic oxides with haloïd salts (corresponding to the basic salts of the oxygen acids) are variously named: thus, oxychloride, bisoxychloride, basic chloride, bibasic chloride. The numerals here refer not to the number of atoms of oxygen and halogen, but to the proportion of metal combined with oxygen and halogen respectively (or perhaps more correctly to the proportion of *equivalents* of oxygen and halogen): thus $2PbO.PbCl_2$ is bisoxychloride, or bibasic chloride. It is to be noted that corresponding basic haloïd and oxygen salts have not the same numeral; as—

$PbO.PbCl_2$ is basic chloride (einfach basisches Chlorid).

$PbO.Pb(NO_3)_2$ is bibasic nitrate (zweifach basisches Salz), because it is $2PbO.N_2O_5$.

$2PbO.PbCl_2$ is bibasic chloride (zweifach basisches Chlorid).

$2PbO.Pb(NO_3)_2$ is terbasic nitrate (dreifach basisches Salz), because it is $3PbO.N_2O_5$.

Sulphur Salts.—(Table 14.)

These have sometimes, especially in German, been named as double sulphides, but usually, in Latin, English, French, and recently also in German, follow the names of the corresponding oxygen salts.

Sulphur Basic Salts.—(Table 13.)

Compounds of normal salts with sulphides of the metal. These were discovered by H. Rose, and called by Berzelius sulphur basic (schwefel basisch), as corresponding to the compounds of normal salts with the basic oxide. This nomenclature has not been generally adopted, and, and, as will be seen from the table, there is little uniformity in naming these substances.

Double Salts.

With very few exceptions, these may be classified in two sets. 1. With a common salt radical. 2. With a common metal. 1. With a common salt radical. Here again there are two kinds. (*a*) Salts of polybasic acids. (*b*) Compounds of two haloïd salts, or of a haloïd salt, with a compound of a halogen and a non-metallic element.

(*a*) These are named consistently with the names of the simple salts; as phosphate of magnesia and ammonia, phosphorsaure ammoniakmagnesia, magnesium ammonium orthophosphate, ammonic magnesic phosphate, or, with what may perhaps be called an adverbial modification of the first adjective, ammonio-magnesic phosphate.

(*b*) Of these we may take as examples $2KF, SiF_4$; $2KCl, PtCl_4$; 2KCN, $Pt(CN)2$; KF, BF_3; $KCl, AuCl_3$;

4KCN, $Fe(CN)_2$; 3(KCN),$\frac{1}{3}Fe(CN)_3$. See Tables 15, 16, 17.

These have been named on three different principles:—

(α) As double fluorides, chlorides, &c.; for instance, fluoride of silicon and potassium, fluorkieselkalium.

(β) As compounds of the positive metal with a compound salt radical; for instance, ferrocyanide of potassium, silicofluoride of potassium, kieselfluorkalium.

(λ) As analogues of oxygen salts; for instance, fluosilicate of potassium, potassium fluosilicate, potassium chlorplatinate, chloraurate, cyanaurate.

The third system seems only to be used when there is really a corresponding oxygen compound.

2. With a common metal. As a well-known substance mentioned by most systematic writers, emerald green has been selected—Table 18. It will be seen that where a name is given, it is either acetate and arsenite, or a combined name, acetoarsenite, or arsenigessigsaures Salz.

PROCEEDINGS OF SOCIETIES.

CHEMICAL SOCIETY.

Thursday, February 18th, 1886.

Dr. Hugo Müller, F.R.S., President, in the Chair.

The certificate of Mr. Charles Kilpatrick, Dearnley, near Rochdale, Lancashire, was read for the first time.

The following changes in the Council, proposed by the Council, were announced:—

As Vice-Presidents: Prof. Dewar, F.R.S., and Mr. David Howard, vice Dr. Schunck, F.R.S., and Mr. W. Weldon, F.R.S. (deceased).

As Members of Council: Messrs. J. A. R. Newlands, S. U. Pickering, Prof. Ramsay, and Dr. Stevenson, vice Dr. E. Atkinson, Prof. G. C. Foster, F.R.S., Mr. Ludwig Mond, and Mr. C. O'Sullivan, F.R.S.

Prof. Wyndham Dunstan, Dr. Percy Frankland, and Mr. Makins were appointed by the Meeting to audit the Society's accounts.

The following papers were read:—

14. "*The Constitution of Undecylenic Acid as indicated by its Magnetic Rotation: and on the Magnetic Rotation, &c., of Mono- and Di-allylacetic Acids and Ethylic Diallylmalonate.*" By W. H. Perkin, Ph.D., F.R.S.

When investigating the magnetic rotation of compounds (*Trans.*, 1884, 421) undecylenic acid was amongst those selected for examination as examples of the series of unsaturated monobasic acids having the formula $C_nH_{2n-1}COOH$. The numbers obtained, however, were lower than was expected, and did not appear to be consistent with those given by other members of this series, and were therefore kept back for the purpose of further investigating the apparent discrepancy.

Both the acid and its ethylic salt were examined. The acid, purified by rapid distillation under reduced pressure (b.-p. 230° to 235° at 130 m.m.) gave a molecular rotation of 12·547. The ethylic salt boiled at 263·5° to 265·5° (corr.), and gave a molecular rotation of 14·530.

Comparing these numbers with those of the corresponding saturated compounds, we get—

		Difference due to unsaturated character.
Undecylenic acid	12·547	+ 0·897
Undecylic „	11·650	
Ethylic undecylenate ..	14·530	+ 0·890
„ undecylate	13·640	

On reference to the table given in the author's former paper (*Trans.*, 1884, 561) it will be seen that these differences are much lower than those (1·112) obtained for ethylic α-crotonate and oleate, but very nearly equal to those (0·914) found in the case of allyl substitution-products.

As these numbers were obtained before the author became aware of the influence of the magnetic field on the optical parts of the polarimeter, it was deemed advisable to re-examine the ethylic salt. The molecular rotation then obtained was 14·543, thus making the difference due to saturation 0·903, or almost identically that previously found with unsaturated compounds containing the allyl-group. As this appeared to indicate that undecylenic acid is an allyl compound, it was determined to examine allylacetic acid for the purpose of comparison. This was prepared by heating allylmalonic acid as long as carbonic anhydride was evolved, and fractioning the residue. It boiled at 185° to 188° (corr.), and gave a molecular rotation of 6·426. From this we get almost the same difference as with the undecylenic compounds:—

Allylacetic acid	6·426
Valeric „	5·508
Difference	0·918

It is thus seen that undecylenic acid and its ethylic salt possess magnetic rotations which are peculiar to mono-allyl derivatives of the fatty acids.

The next question is as to the position of the allyl-group, as it is probable that the magnetic rotation would be the same whether it were, for example, an allyl-hexyl-acetic acid or an allyl-octylic acid:—

$C_3H_5 \cdot CH(C_6H_{13}) \cdot COOH$ or $C_3H_5 \cdot C_7H_{14} \cdot COOH$.

But Krafft has shown that when oxidised with nitric acid it yields normal sebacic acid; and there can therefore be scarcely a doubt that undecylenic acid is allyloctylic acid, $CH_2{:}CH \cdot CH_2(CH_2)_7 \cdot COOH$.

Whilst working on this subject it was thought interesting to prepare and examine diallylacetic acid. This was made from diallylmalonic acid, and boiled at 227° to 227·5° (corr.). It gave a molecular rotation of 10·344. The molecular rotation calculated for octylic acid is 8·577. There is thus a difference of 1·767 for the influence of the two allyl-groups. Deducting 0·903 for the first allyl-group, we get 0·864 for the second,—a result consistent with previous results (see former paper), which showed that the influence decreases with successive displacements.

The re-determination of the molecular rotation of ethyl diallylmalonate in a freshly-prepared specimen gave 15·025, or a number differing by only 0·027 from that (14·998) given in the former paper.

15. "*Reactions supposed to yield Nitroxyl or Nitryl Chloride.*" By W. Collingwood Williams, B.Sc.

Direct union of chlorine and nitrogen peroxide does not take place either at a red-heat or at 150° C., nor does the action of chloranhydrides (such as phosphorus oxychloride or sulphuryl chloride) on nitric acid or nitrates yield nitryl chloride.

When chlorine and nitric peroxide are passed through a red-hot tube the product is a mixture of nitric peroxide and nitrosyl chloride containing chlorine in solution, while oxygen gas is liberated. This result is due to the dissociation of NO_2 into $NO + O_2$ at a red-heat.

When the tube is heated to 150° C. only, no appreciable change occurs, the product being a solution of chlorine in the peroxide, and an exactly similar product is yielded by all the other methods examined.

16. "*The Condition of Silicon in Cast-Iron.*" By A. E. Jordan and Thomas Turner.

The authors have endeavoured to ascertain whether crystallised silicon can be separated from cast-iron. They refer to the work of Wöhler, Richter, and others, who believed that they had obtained crystals of silicon, and also to the experiments of Snelus, Morton, and Tilden, who were unable to separate silicon from cast-iron in this form.

1. Several irons, including a specimen of pig containing 9·8 per cent silicon, were submitted to magnetic examination. Though both graphite and slag could be separated by means of the magnet, it was not found possible to separate silicon in this manner.

2. The residue left after prolonged boiling with dilute hydrochloric acid was then studied. After drying, the graphite was burned off in a muffle, and the remainder examined for silicon. In no instance was silicon found; but in the case of a pig with 10·3 per cent silicon, black scales were obtained of very difficultly decomposable iron silicide. These scales appear to closely resemble in properties the so-called graphitic silicon of some other observers. In the residue, before roasting, the authors found a quantity of substance resembling Wöhler's "leucome," the "silicon formanhydride" of Friedel and Ladenburg.

3. Lastly, graphitic matter from iron was examined. For the two specimens used they are indebted to Dr. Percy. The first was graphite from Dowlais, which had previously been examined by Dr. Percy, who suggested that it might contain crystallised silicon (*Iron and Steel*, p. 145). It was found to be nearly pure carbon, and to be almost entirely free from silicon in any form. A specimen of kish, from Clarence Works, Middlesbro', was also examined, but in this case too no crystallised silicon was found.

The authors conclude that silicon is present in cast-iron in the form of silicide, being probably a solidified solution in the excess of iron.

Discussion.

The President remarked that the results now brought forward pointed to the importance of direct synthetic experiments with silicon and iron as a means of ascertaining whether graphitic silicon can separate from iron under any conditions. Since it had been shown that the supposed crystalline modifications of boron were compounds with aluminium and carbon (Hampe, *Annalen*, 1876, 183, 75), even the existence of a graphitic silicon appeared doubtful.

Mr. Turner said, that although he had not been able to make such experiments, he had examined irons containing up to 10 per cent of silicon, and had always found the silicon to be present in the one form.

Sir Frederick Abel desired to express his concurrence in the conclusions arrived at by the authors, that there appeared to be no grounds for considering that silicon might exist in cast-iron in the graphitic or crystalline form, or that this element might occur in two different conditions in cast-iron, as carbon did. The result of very numerous experiments and the careful examination of many graphitic residues obtained from cast-iron, had long since led him to these conclusions, but he hesitated referring to his own special experience of many years back in connection with the chemistry of cast-iron, after the remarks which Professor Unwin was reported to have made on the occasion of Mr. Turner's last paper as to the condition of the chemist's knowledge of cast-iron 30 odd years ago. He had been as much surprised as amused to learn that at about the date when certain questions relating to a supply of iron to Woolwich arose, to which Professor Unwin had referred, the methods of determining carbon were faulty, and no distinction was drawn between graphitic and combined carbon. It was true that

the analytical results given in the Woolwich Report, "Cast-Iron Experiments, 1858," included statements of the proportions of graphite only in the partial analyses of samples then carried out for a special object; but in an Official Report, published two years previously by the War Office, the results of analyses of a number of specimens of cast-iron used in the manufacture of ordnance included the items of "total carbon" and "carbon as graphite." In a paper contained in the Quarterly Journal of this Society for 1857, the proportions of *combined carbon* and of graphite existing in specimens of cast-iron of foreign manufacture were also given by Sir Frederick. As regards the methods of analysis practised in those days, and which had been for some time previously taught at the School of Mines and elsewhere, they were in all essential respects similar to and as trustworthy as those now in use. He had learned with surprise that the eminent engineer who had made those criticisms on the work of 30 years ago, and thought it sufficient for his purpose to refer only to the work of one who certainly was never accepted by chemists as an authority on iron analysis.

As regards the matter of the Nova Scotia iron to which Professor Unwin had referred, and which was dealt with in 1858, not 1853, it was right he should state that a quantity of iron called Nova Scotian, supplied for gun-manufacture, was rejected, *not* "because the Chemical Department refused to sanction its use on the ground that it contained too much silicon," but because, instead of being a grey iron somewhat siliceous but otherwise of high quality, having the characters of charcoal-iron—as was the case with the sample of Nova Scotia iron which led to the purchase of a supply, it consisted in large proportion of white and light mottled iron, some of which contained as much as from 1 to 2 per cent. of phosphorus. Certain experiments were made on the effect of melting selected samples of this supply high in silicon, with the result that the strength of the metal was increased without a very material alteration in the proportion of silicon, but these results had no bearing upon the fitness of even this metal to resist powder-strains, nor upon the question whether the supply should not be rejected. The matter having been submitted to arbitration, Mr. Fairbairn, as umpire, decreed in favour of the rejection. In conclusion he ventured to assure Professor Unwin that, by reference to the literature of that time, he would find that chemists were by no means far behind their brethren of the present day in regard to their knowledge of methods of analysis and properties of cast-iron.

17. "*Certain Aromatic Cyanates and Carbamates.*" By H. Lloyd Snape, B.Sc.

The author finds that on heating phenyl cyanate with pyridine it is converted into *diphenyl dicyanate*, $C_{14}H_{10}N_2O_2$. He has prepared a number of dicyanates by the action of carbonyl chloride on dyamines, and has studied their behaviour with alcohols, as in his previous work on phenyl cyanate (*Chem. Soc. Trans.*, 1885, 770). *Diphenylene diisocyanate*, $CO:N\cdot C_6H_4\cdot C_6H_4\cdot N:CO$, was obtained from benzidine hydrochloride and phosgene; on treatment with alcohol it is converted into *diphenylene diurethane*, $COOEt\cdot NH\cdot C_6H_4\cdot C_6H_4\cdot NH\cdot COOEt$, which may also be prepared from benzidine and ethylic chloroformate; the corresponding phenylated urethane is obtained by the interaction of phenol and diphenylene diisocyanate.

Metatoluylene diamine and phosgene react to form metatoluylen diisocyanate, which is converted by phenol into the carbamate $Me\cdot C_6H_3(NH.COOPh)_2$.

No cyanate was formed on heating orthotoluylenediamine with phosgene; both this diamine and orthophenylenediamine, however, react with ethylic chloroformate to form urethanes.

On heating phenyl hydrazine at 220—230° in an atmosphere of carbonyl chloride, a solid compound of phenyl cyanate with hydrogen chloride was formed.

18. "*The Oil obtained from Lime-Leaves.*" By Francis Watts.

The fragrant yellow oil of the lime-tree (*Citrus limetta*) obtained by distilling the leaves and young shoots in a current of steam, contains a citrene, $C_{10}H_{16}$, boiling at 178—179°, and methylnonyl ketone; it appears also to contain "terpinol." On distillation about one-half boils above 280° and has the appearance of colophene.

At the next meeting, on March 4th, there will be a ballot for the election of Fellows, and the following papers will be read:—

"The Influence of Temperature on the Heat of Chemical Combination." By S. U. Pickering.

"The Action of Heat on the Salts of Tetrethylphosphonium." By N. Collie.

"A New Method for the Preparation of Tin Tetrethyl." By N. Collie and Professor Letts.

NOTICES OF BOOKS.

Electro-Deposition; a Practical Treatise on the Electrolysis of Gold, Silver, Copper, Nickel, and other Metals and Alloys, with Descriptions of Voltaic Batteries, Magneto and Dynamo-Electric Machines, Thermopiles, and on the Materials and Processes used in every Department of the Art, and several chapters on Electro-Metallurgy. By Alexander Watt. London: Crosby Lockwood and Co.

This book opens with three historical chapters giving an account of the rise and progress of Voltaic electricity—without mention of the anticipation of Galvani's initial experiment by the illustrious Dutch naturalist, Swammerdam—of electro-magnetism, magneto-electricity, dynamo-electricity, and thermo-electricity, which latter Mr. Watt believes has before it a great future, the thermo-pile being the only example of the direct conversion of heat into electric energy, and as far as is known this is generated without any other waste beyond that of the fuel consumed in generating the heat necessary.

The fourth chapter gives from original sources the history of electro-deposition. Our readers will doubtless be surprised to learn that the earliest successful experiments were made by Sir H. Bessemer when a youth of eighteen, anticipating Jacobi by about seven years, and that Jordan was the first to publish a definite process.

In the fifth chapter we find a theory of electrolysis, whilst in the following section there is an examination of electrical theories in their relation to the deposition of metals. The processes for coppering, gilding, and silvering are next expounded with great minuteness.

The electro-deposition of nickel, tin, iron, zinc, and some of the metals less generally used is next considered, followed by instructions for the deposition of alloys, such as brass, bronze, and German silver.

We have then three chapters on electro-metallurgy, under which head rank processes for refining copper and lead; for the electrolytic refining of gold, silver, and copper ores, and for the electro-chlorination of gold ores.

In conclusion follow chapters on some mechanical operations subsidiary to electro-deposition, on the recovery of the precious metals from waste solutions, and on stripping metals from each other.

A separate chapter is devoted to the consideration of the chemical agents used in the electro-plastic art.

Under the heading "Useful Information" Mr. Watt gives hints on the management of batteries, their relative power, intensity, and constancy; tests for free cyanide, and remedies in case of poisoning. Such information is exceedingly valuable to all persons obliged to manipulate so formidable a poison as potassium-cyanide. Accidents from this substance are not unfrequent in electro-plating

works. Indeed, the author confesses to having been three times placed in some danger by swallowing a solution of cyanide, or inhaling its fumes. He recommends that the coldest water procurable should be poured upon the head and allowed to run down the spine of the sufferer, whilst ammonia or bleaching lime is cautiously applied to the nostrils. He even recommends that this acid should never be used without a second person holding a phial of one of these agents near the nose of the operator. We should recommend as a more excellent way to hold the breath entirely whilst pouring out hydrocyanic acid from a bottle, or never to work with it except under a good draught-hood.

Mr. Watt's work will be very serviceable to technical students, to apprentices, workmen who are seeking to qualify themselves for more responsible positions, and, if we may venture to say so, to manufacturers who feel the necessity of discarding rule-of-thumb and combining in future practice with theory.

Sound, Light, and Heat. By ALFONZO GARDINER. Part I., Elementary Stage. Manchester and London: J. Heywood.

THAT this manual meets a want of the present day is at once apparent seeing that it has reached its fourteenth edition. The examinational character of the work is most pronounced, as it will be seen not merely from the prefaces to successive editions, but from numerous foot-notes which seem designed to meet a possible question. We are compelled to call attention to a significant passage in the preface to the thirteenth edition, premising that we by no means blame Mr. Gardiner, but the vicious system to which he and numbers of other competent and doubtless conscientious teachers are compelled to conform. Says the author, "The curse of the present day, as regards examinations, is the studying of brief outlines, and trusting to them *alone* as being sufficient for the purposes. (What purposes?) The result is that cram takes the place of that thorough knowledge which enables a student to 'tackle' a question when it is presented in an unusual form, and out of the abundance of his knowledge to show an examiner that, if he has not learnt everything, he has at least learnt something, and knows that something well."

So the purpose of scientific study is not mainly a mastery of the art of correct and thorough observation, not the power of extending human knowledge by discovery, not the application of established truths to useful purposes, but "tackling" a question and showing an examiner something! We submit that the curse of education in the present day is examination—in the form which it assumes in England.

Year-Book of Pharmacy: comprising Abstracts of Papers relating to Pharmacy, Materia Medica, and Chemistry, contributed to British and Foreign Journals, from July 1st, 1884, to June 30th, 1885, with the Transactions of the British Pharmaceutical Conference at the Twenty-second Annual Meeting, held at Aberdeen, September, 1885. London: J. and A. Churchill.

IN that part of the present volume which comprises extracts from memoirs read before the learned societies, or published in the scientific journals, we are glad to note a generally good classification. Processes for the manufacture or for the analysis of non-pharmaceutical products are no longer found under the heading "Pharmacy." "Bibliography" is a very useful chapter, giving, as it does, the titles of all the most important works on Chemistry which have appeared during the past twelve months.

In the *Transactions* we note with pleasure the absence of any proposals for more stringent regulations on the sale of poisons, seeing that no further steps can be taken in that direction without seriously interfering at once with industry and with scientific research. The latter consideration, indeed, would weigh very lightly with the Legislature.

Mr. W. Gilmour communicated an interesting paper on Cotton-seed Oil. This oil, when refined, has the mean specific gravity of 0·920 to 0·921. It ranks midway between the drying and the non-drying oils. For dietetic purposes it must be well adapted, as it has no disposition to become rancid even on prolonged exposure to sunshine. It does not saponify readily, at least in an unmixed state. Oil from the Egyptian seed is said to be superior to the American product.

Mr. D. B. Dott gives the volatilisation of mercuric chloride as 0·0088 per cent daily.

Mr. M. Dechan read a paper on Carmine. Like Dr. Hugo Müller, he had vainly tried to prepare carmine by Madame Cenette's process, "the only and invariable result being a rich crop of mould." He seems to have noticed the presence of lime as well as alumina combined with the colouring-matter; it is soluble in ammonia. He refers, however, to a novel possible adulteration. Tin spirits form with aniline scarlet a compound which much resembles carmine physically and chemically, being, like it, soluble in dilute ammonia, but insoluble in water. Hence a sample which dissolves without residue in dilute ammonia is not necessarily genuine. One sample examined contained 50 per cent of vermilion.

University College of South Wales and Monmouthshire. The Calendar. Third Session, 1885—1886. Cardiff: Daniel, Owen, and Co., Limited.

THE constitution of this College seems very complicated, there being a Court of Governors, a Council, and a Senate, the powers and duties of which bodies do not seem defined with sufficient clearness. In most Universities one ruling body, the Senate, is amply sufficient. Neither in the Court of Governors nor in the Council do we detect the names of any eminent scientific men. There are a few medical practitioners, but lawyers and ministers of all denominations seem to exceed them in number. As regards the professorial staff there are chairs of physics, of chemistry, and of biology, each Professor in the two former departments being assisted by a Demonstrator. Six professorships are devoted to languages, one to logic and philosophy, and one to mathematics and astronomy. There is also the English peculiarity, so perplexing to foreigners, of a professorship of music.

In chemistry there are three courses of instruction,—a junior, an intermediate, and a senior. For the second of these courses the authorised text-books are Thorpe's "Manual of Inorganic Chemistry" or Kolbe's "Inorganic Chemistry," with, for more advanced work, Miller, vol. ii., or Roscoe and Schorlemmer, vols. i. and ii. For chemical theory Tilden's "Chemical Philosophy," and Wurtz on the Atomic Theory are recommended, Mr. Pattison Muir's work being curiously passed over.

The senior course is devoted to organic chemistry. The text-books selected are Armstrong's and Fownes's, and for more advanced work Roscoe and Schorlemmer, vol. iii., or Miller, vol. iii. The laboratory is fitted with twenty-two work-benches. Every student who works twelve hours weekly, or upwards, has a separate bench.

The library appears fairly well stocked, as far as the number of books is concerned, but philology, history, &c., decidedly preponderate over the physical and natural sciences.

Whether the University College of South Wales will become a focus of research time only can decide.

CHEMICAL NOTICES FROM FOREIGN SOURCES.

Note.—All degrees of temperature are Centigrade unless otherwise expressed.

Comptes Rendus Hebdomadaires des Séances, de l' Académie des Sciences. Vol. cii., No. 6, February 8, 1886.

Process for Preparing Ortho-phosphoric Acid and for Titrating Phosphoric and Arsenic Acids by means of Various Indicators.—A. Joly.—The author dissolves in heat pure ammonium monophosphate in strong hydrochloric acid. Ammonium chloride, sparingly soluble in the strong acid, is deposited. The acid liquid is phosphoric acid mixed with hydrochloric acid and still retaining some ammonium chloride in solution. This liquid is decanted, the sal-ammoniac is drained with the filter-pump, repeatedly washed with a little hydrochloric acid, and all the acid liquids are collected in a porcelain capsule, slightly heated, and mixed with nitric acid in small successive portions, so as to destroy the ammonia and gradually expel the hydrochloric acid. When this acid has been entirely eliminated the evaporation is completed in a platinum capsule. The excess of nitric acid is thus expelled and there remains a syrupy liquid which may serve for the preparation of the two crystalline hydrates of ortho-phosphoric acid. If the ammonium phosphate is arsenical, which is very frequently the case, this impurity must first be removed. Phosphoric acid may be titrated with caustic alkali with a degree of precision which is sufficient in most cases, using as indicator orangé No. 3. Phenol-phthalein gives very imperfect results, for the final colouration passes from light violet to a violet red. As for the blue C_4B, the reactions of which have been studied by M. Engel, it does not seem to the author to admit of precise applications. The volumes of one and the same solution of soda (1 eq. = 2 litres) indicating the saturation of 50 c.c. of a solution of phosphoric acid (1 eq. = 6 litres) are, with orangé, 19·9 c.c.; with phenol-phthalein, 39·2 and 40·1; and with blue C_4B 41·0. Arsenic acid gives almost identical results, yet the uncertainty of the change with orangé; the liquor changes colour with phenol-phthalein before two eq. of base have been added, and in presence of blue C_4B the change of tint shows itself a little later than that with phenol-phthalein. For titrating the solutions of arsenic and phosphoric acid in order to study the composition of their hydrates the author has for a long time made use of a more precise method. After having mixed the acid liquid with some drops of phthalein he adds a standard solution of baryta until a gelatinous precipitate is distinctly formed. This precipitate is a tribarytic salt which, in contact with the surrounding acid liquid, is converted spontaneously, or by agitation, into a crystalline bibarytic salt. On slowly adding baryta water we obtain a new gelatinous precipitate, and the operation is complete when a drop of baryta gives an intense and persistent red colour. The transformation of the gelatinous precipitate is particularly rapid with arsenic acid, and this is the only method of titration which it is possible to employ.

Action of Acetic Acid upon Oil of Turpentine.—MM. Bouchardat and Lafont.—Acetic acid combines with oil of turpentine even in the cold, yielding mono-acetates belonging to two quite distinct series. The uncombined oil is transformed into two carbides, $C_{20}H_{16}$, the one monovalent, analogous to turpentine, the second bivalent, or an active terpilene.

Die Chemische Industrie.
Vol. ix., No. 1, January, 1886.

Attempt at a Qualitative Analysis of the Commercial Coal-Tar Dyes.—Dr. Otto N. Witt.—A useful but extensive survey of the reactions of the principal coal-tar colours, other than those of the anthracene group, which will be inserted at some length as early as possible.

On Chlorozone.—G. Lunge and L. Landolt.—The authors point out that two modifications of chlorozone occur in commerce; the one recently examined by L. Storck, consisting of sodium hypochlorite, chloride, and hydroxide, and that examined by the present authors, and consisting essentially of free hypochlorous acid and sodium chloride.

The History of the Ammonia-Soda Process.—Ludwig Mond.—The author refutes the claims advanced by MM. Fremy, Bouley, and Scheurer-Kestner on behalf of MM. Schlœsing and Rolland, and shows from patent specifications that this process was invented by Harrison, Grey, Dyar, and John Hemming, and patented June 30th, 1838, whilst Schlœsing's patent was only taken out in 1854, and that of Schlœsing and Rolland in 1858.

Bulletin de la Société Chimique de Paris.
Vol. xliv., No. 8, Nov. 5, 1885.

Purification of Sulphuric Acid and Preparation of Nitric Acid.—Prof. Kupferschlæger.—All chemists know that commercial sulphuric acid, prepared from iron pyrites, contains lead and calcium sulphates, nitrous and sulphurous vapours, arsenic acid, sometimes selenious acid, thallium sulphate, and hydrogen fluoride. For its purification the author dilutes it with its own weight of water, then passes through it in excess a current of washed sulphurous acid, so as to bring the arsenic and nitric acids to a lower stage of oxidation, and to reduce selenious acid if present. A current of hydrogen sulphide is then passed through it twice, with an interval, each time as long as it is absorbed. The vessel is then closed, and allowed to stand for some time at a moderate temperature, so that the lead and arsenic sulphides, selenium, &c., may subside. The sulphuric acid is then rectified in glass retorts, applying the heat so as to reach the upper portion only.

Revue Universelle des Mines, de la Metallurgie, &c.,
Novembtr and December, 1886.

This issue contains no original chemical matter.

Bulletin de la Société Chimique de Paris.
Vol. xlv., No. 3, February 5, 1886.

Contributions to the History of Sulphur and Mercury.—M. Berthelot.—Pure sulphur sublimes slightly at 60°, carrying along with it mechanically small quantities of fixed matters. The vapour-tension of this slow sublimation effected at 380° below the boiling-point is not appreciable by manometric measurements. The evaporation of mercury at common temperatures is known; and the vapour-tension of mercury, calculated according to Regnault's formulæ, would be at 20° 0·0268 metre.

On Oxalic Acid in Vegetation: Methods of Analysis.—MM. Berthelot and André.—Already noticed.

On Carbonates in Living Plants.—MM. Berthelot and André.—Plants contain carbon principles capable of being split up under the influence of natural ferments or on prolonged ebullition, yielding alkaline carbonates, or rather bicarbonates.

Direct Fixation of Free Atmospheric Nitrogen by certain Clay Soils.—M. Berthelot.—Already noticed.

Solubility of Copper Sulphate in presence of Ammonium Sulphate.—R. Engel.—Increasing quantities of ammonium sulphate precipitate copper sulphate in the state of a double salt.

Observations on the Nature and the Properties of the Alkaloids.—M. Oechsner de Coninck. The com

pounds which have been termed volatile alkaloids are pyridic or dipyridic hydrides. The so-called fixed alkaloids are bodies with a double nucleus, either hydro-dipyridic or hydro-diquinoleic, or with a double mixed nucleus both hydro-pyridic and hydro-quinoleic, nuclei whose hydrogen is substituted by one or more oxygenated radicles, and containing hydroxyls either of a phenic or an alcoholic function. The alkaloids are in general transformed by oxidation, either partially or totally, into pyridine-carbonic or quinoleine-carbonic acids. An alkaloid is a nitrogenous substance which oxidising agents convert into pyridine-carbonic or quinoleine-carbonic acids, or into a mixture of one of these acids and of a fatty or an aromatic acid.

The Law of Thermic Constants.—D. Tommasi.—M. Tscheltzow has recently determined the combination-calories of certain picrates. The values which he has obtained by means of the calorimeter are the same as the combination calories which the law of thermic constants enabled the author to foresee more than two years ago. The memoir concludes with this remark:—M. Berthelot maintains that the law had been previously known. But if so, why did it not figure in his "Traité de Mecanique Chimique"?

Electrolysis of certain Chemical Compounds.—D. Tommasi.—The author studies the electrolysis of potassium chlorate and perchlorate, and of chloral hydrate. In the latter decomposition chlorine goes to the kathode along with hydrogen, but these two elements remain in presence of each other without combining.

Combinations of Gold Trichloride with Sulphur and Selenium Tetrachlorides.—L. Lindet.—The combinations of gold trichloride with phosphorus perchloride, and with sulphur and selenium tetrachlorides, demonstrate that gold trichloride may play the part of a basic chloride in double compounds. The compounds previously obtained of gold chloride with the alkaline, alkaline-earthy, and metallic chlorides caused it to be regarded as an acid chloride. Gold trichloride is therefore indifferent, like auric acid.

New Solvents of Anhydrous Gold Trichloride.—L. Lindet.—Certain acid chlorides do not enter into combination with gold trichloride, but dissolve it, and allow it subsequently to crystallise out on cooling. Such chlorides are arsenic trichloride, silicon tetrachloride, antimony pentachloride, tin and titanium dichlorides.

MISCELLANEOUS.

The late Mr. A. Tribe.—The recent unexpected death, at the age of 46, of Mr. Alfred Tribe, has left a widow and four children in decidedly straitened circumstances. The eldest son being barely sixteen and not strong, is not yet able to contribute to the support of the family; in addition, there are two girls of 7 and 8 respectively, and a baby boy of 2 years. It has accordingly been thought desirable that a fund should be raised to aid in their maintenance and education, and for this purpose a Committee has been formed. The large amount of scientific research conducted during upwards of 20 years past by Mr. Tribe (partly published by himself, partly in conjunction with Dr. Gladstone, F.R.S), on subjects chiefly connected with various branches of chemical and electrical science, is well known to those interested in such matters: whilst for many years past Mr. Tribe was Chemical Lecturer at Dulwich College and Lecturer on Dental Metallurgy at the National Dental Hospital; and in these capacities became well known to and highly esteemed by a large number of students and pupils. Subscriptions will be gladly received at our Office, or they can be sent to Dr. Alder Wright, Chemical Laboratory, St. Mary's Hospital, W.

MEETINGS FOR THE WEEK.

MONDAY, March 1.—London Institution, 5.
—— Society of Arts, 8. (Cantor Lectures). "Science Teaching," by Prof. F. Guthrie, F.R.S.
—— Society of Chemical Industry, 8. "Ice Making and Cooling Machinery," by T. B. Lightfoot, M.I.C.E.
—— Medical, 8.30. (Anniversary).
—— Royal Medical and Chirurgical, 8. (Anniversary).
TUESDAY, 2nd.—Institution of Civil Engineers, 8.
—— Pathological, 8.30.
—— Royal Institution, 3. "The Unexhibited Portion of the Greek and Roman Sculptures in the British Museum," by C. T. Newton, C.B.
—— Society of Arts, 8. "Bechuanaland and Austral Africa," by John Mackenzie.
WEDNESDAY, 3rd.—Society of Arts, 8. "Calculating Machines," by C. V. Boys.
THURSDAY, 4th.—Royal, 4.30.
—— London Institution 7.
—— Royal Institution, 3. "The Ancient Geography of Britain," by Prof. W. Boyd Dawkins, F.R.S.
—— Parkes Museum of Hygiene, 8. "Metropolitan Defences against Infectious Diseases," by Shirley Murphy.

THE DIASTATIC ACTION OF SALIVA, AS MODIFIED BY VARIOUS CONDITIONS, STUDIED QUANTITATIVELY.*

By R. H. CHITTENDEN and HERBERT E. SMITH.

THE chemical changes resulting from the action of unorganised ferments are among the most interesting and important of those which occur in the animal organism. Ferment action plays such an important part in the chemical processes incident to life that definite knowledge of the conditions favourable and inimical to the action of any ferment occurring in the animal body must necessarily be of great physiological value.

Since Leuchs, in 1831, discovered the diastatic action of saliva much has been learned regarding this digestive fluid, both as to its chemical action and the nature of the products formed. Still there has been lacking, until recently, definite knowledge of the conditions which influence the diastatic action of the salivary ferment; and it has been the object of the present investigation, taking advantage of previously acquired knowledge, to ascertain the exact influence of those conditions which suggest themselves as being most important in view of the destination of the ptyalin, and concerning which there has been of late a lack of agreement.

Method used in Determining the Rate of Diastatic Action.

In testing the rate of action of the salivary ferment we have in all cases employed quantitative methods, similar in their general nature to those previously used by one of us.† The amount of reducing substances formed by the amylolytic action of the ferment, which for the sake of convenience we have calculated as dextrose, admit of accurate determination by means of the improved Allihn's‡ method, and thus enable us to give a concise expression of the relative diastatic action, even in those cases where the differences are very slight. As recent experiments|| have plainly indicated, the ultimate product of the diastatic action of ptyalin is dextrose; the sugar intermediate between this body and the dextrins, and which is formed in much larger quantity, is maltose, with a relative reducing power of 66 as compared with dextrose, 100; while the achroodextrins and other intermediate products have very small reducing power: consequently the reducing power of a digestive mixture must necessarily express the relative diastatic action of the ferment present, since increased action means an increased formation of reducing bodies, of which the final product has the highest reducing power. In this connection it is well to remember that diastase and ptyalin both convert only a limited quantity of starch into sugar or reducing bodies,§ and that no matter how great the excess of ferment, or the length of time the action is continued, the percentage of starch changed into sugar does not ordinarily exceed 53 per cent.¶ The general method employed in our work for testing the diastatic action of saliva was as follows:—The volume of the digestive mixture was in every instance 100 c.c.; the amount of starch* present, 1 or 2 grms., previously boiled in a definite amount of water; the temperature of digestion 38° to 40° C.; the length of time generally 30 minutes. When the digestion was finished, diastatic action was at once stopped by boiling the mixture; when cold the mixture was diluted with distilled water to 200 c.c. and filtered; 25 c.c. of the filtrate, or one-eighth of the entire fluid, was then precipitated with Fehling's solution according to Allihn's† data and method; the reduced copper was filtered through an asbestos filter in a small weighed glass tube, and ignited directly in a current of hydrogen gas and weighed as metallic copper. By means of Allihn's tables of reduction equivalents the corresponding amount of sugar, calculated as dextrose, is easily obtained, from which the percentage amount of starch converted into reducing bodies can be computed, calling dextrose $C_6H_{12}O_6$, and the starch $C_6H_{10}O_5$.‡ The following experiment illustrates the accuracy of the method and the reliance which can be placed upon it; two solutions of 100 c.c., each containing 2 grms. of starch and 4 c.c. of filtered saliva, were warmed at 40° C. for four hours, then examined with the following results:—

	Wt. Cu in one-eighth.	Total amount of Sugar.	Starch converted into Sugar.
I.	0·1530 grm.	0 6248 grm.	28·13 per cent.
II.	0·1523 ,,	0·6216 ,,	27·91 ,,

Relation of Dilution to Diastatic Action.

It is a fact well understood that the chemical action of a ferment is out of all proportion to the amount of ferment present; indeed a given solution of a ferment can be diluted again and again without any marked difference in its chemical activity, or at least none at all proportionate to the degree of dilution. It is only when the dilution has been carried to the extreme limit that the relative power of the mixture can be taken as a measure of the amount of ferment present.

The following experiments illustrate the foregoing statement. Each digestive mixture was 100 c.c. in volume, and was warmed at 40° C. for thirty minutes. The only variations in the different mixtures consisted in the amount of saliva and starch.

From these results it is seen that only when the dilution of normally alkaline saliva is as 1 : 50 or 100 does the diastatic action at all correspond to the amount of ferment present. The same is to be noticed in Grützner's* experiments, where the principle employed by Gruenhagen in the estimation of pepsin was used, the amount of starch dissolved by the saliva being directly proportional to the amount of ferment only when very small quantities of saliva were employed and the time limited to ten or fifteen minutes. Increasing the amount of starch beyond 1 per cent tends to diminish somewhat the amount of sugar formed in a given time, when the dilution of the saliva is as 1 : 50 or 100, which fact agrees well with what we already know concerning the influence on ferment action of the clogging of digestive fluids in general by the products of digestion, or by the substance to be digested; Series III., *a* and *b*. Increasing the length of time for the ferment to act, however, causes a corresponding increase in the amount of sugar formed, as is well seen in Series III., *c*. It would not be at all impossible, therefore, by suitable dilutions, to use this method as a means of determining the relative amounts of ptyalin present in different salivary or pancreatic secretions. The following results, taken from those already given, in addition to others, lends favour to this view. All the experiments were made in the usual way, and the results are expressed in percentage of starch converted into sugar.

	I.	II.	III.
2 c.c. saliva	12·01 p.c.	8·35 p.c.	4·73 p.c.
1	5·79	4·11	2·21
	IV.	V.	VI.
1 c.c. saliva	6·93 p.c.	26·81 p.c.†	24·00 p.c †
½	3·56	13·72	11·34

The degree of dilution to be employed depends, of course, upon the amount of ferment present. We have usually diluted the saliva 5 or 10 times, and then added an amount of the diluted fluid corresponding to 0·5—2·0 c.c. of saliva, which in the 100 c.c. of digestive mixture makes a dilution of from 50 to 200. As we shall have occasion to state later on, neutralised saliva needs even a greater dilution. The method certainly appears as advantageous as that proposed by Dr. Roberts‡ a few years ago, and has the advantage of giving gravimetric results, instead of being dependent upon the disappearance of a shade of colour. In using the method with different solutions it will always be found necessary to exactly neutralise the ptyalin-containing solutions before diluting them, since variations of alkalinity, even though infinitesimal in amount, may produce discordant results. Moreover, it is better to warm the ptyalin solution with the starch for not longer than thirty minutes.

The amount of dilution which saliva will endure, and still show diastatic action, depends naturally upon the amount of ptyalin present in the secretion, and also upon the reaction of the fluid, whether it be alkaline or neutral. The following series of experiments show the average of our results on this point:—

SERIES IV.

Normally alkaline saliva, 1 per cent starch.

	Wt. Cu in one-eighth.	Total amount of Sugar.	Starch converted into Sugar.
1 c.c. saliva ..	0·0152 grm.	0·0704 grm.	6·33 per cent.

1/10 ,, ..	trace } less than 1 per cent of starch converted.		
1/20* ,, ..	trace }		

It is thus seen that when the dilution is as 1 : 250 an appreciable amount of starch is converted into sugar in 30 minutes at 40° C. Even with a dilution of 1 : 1000 or 2000 a recognisable amount of sugar is formed under these conditions. This degree of dilution, however, cannot be considered as being the limit at which diastatic action will show itself, for with even greater dilutions the starch is converted into soluble modifications, coloured blue by iodine, without giving any recognisable amount of reducing substance,—that is, in one-eighth of the digestive mixture. Longer continued action at 40° C. might yield some reducing substance: it would seem, however, from our experiments, that when a certain degree of dilution is reached the action of the small amount of ferment in contact with the larger amount of starch (1 grm. is devoted exclusively to converting the granulose into soluble starch, or other like body with non-reducing action. This agrees with the results obtained by Grützner,† who found that the nature of the products obtained by the action of ptyalin was dependent upon the intensity of the ferment action; with a small amount of ferment erythrodextrin was the main product, while with a large amount of ferment sugar was mainly formed. Diminishing the amount of starch in large dilutions of the saliva tends, as might be expected to increase the amount of sugar formed.

Comparison of the Diastatic Action of Neutralised and Normally Alkaline Saliva.

Human mixed saliva, when freshly secreted, almost invariably possesses a distinctly alkaline reaction. Some time ago one of us published a series of experiments‡ on this point, in which it was shown that the average alkalinity of 51 samples of human mixed saliva, expressed as sodium carbonate, was 0·080 per cent. The extreme variations of alkalinity in the saliva from 14 individuals amounted to 0·085 per cent calculated as sodium carbonate (0·144—0·059 per cent).

We have had occasion to make determinations of alkalinity in 15 additional samples of saliva, all collected by one person. We give the results here, as affording additional data regarding the average alkalinity of this secretion. The alkalinity is calculated, as heretofore, in the form of sodium carbonate.§ The indicator used was delicate litmus-paper.

20	7·80	0·113
20	6·80	0·099
20	8·30	0·120
20	7·60	0·110

Average alkalinity of the 15 samples, 0·097 per cent.

It was demonstrated some time ago by one of us* that neutralised saliva had as great a diastatic power as the unneutralised or normally alkaline. In fact, the single result which we recorded plainly indicated a greater diastatic power on the part of the neutralised saliva, since from the digestion with normally alkaline saliva, one-tenth of the mixture gave 0·0905 grm. metallic copper, while the same quantity of the saliva neutralised gave under like conditions 0·0943 grm. copper; thus showing that the alkaline saliva had converted 41·58 per cent of the starch into sugar, while the same quantity neutralised had changed 43·28 per cent. In these two experiments, however, the amount of saliva used was large, being one-fourth of the entire digestive mixture, viz., 25 c.c.

Recently Langley and Eves† have made the statement that "neutralised saliva converts starch into sugar much more actively than unneutralised saliva," without, however, giving any data. These are the only two statements recorded bearing on the relative diastatic action of the neutralised and normally alkaline secretion.

Our experiments, however, show that there is a very great difference in the action of ptyalin in neutralised and unneutralised saliva; a difference which is more manifest when the saliva is greatly diluted and seemingly out of all proportion to the amount of alkali present, in cases where the dilution is 1:100 or more. The following experiments show the amount of difference.

SERIES V.

The saliva used in this series contained 0·091 per cent alkali, calculated as sodium carbonate:

20 c.c. of the saliva were diluted to 100 c.c. and used in *a*.

20 c.c. of the same saliva were neutralised and then diluted to 100 c.c. and used in *b*.

a. Normally Alkaline Saliva.

	Wt. Cu in one eighth.	Total amount of sugar.	Starch converted into sugar.
4 c.c. saliva ..	0·0652 grm.	0·2672 grm.	24·05 per cent.
2 „ ..	0·0282 „	0·1208 „	10·87 „
1 „ ..	0·0094 „	0·0464 „	4·17 „

b. Neutralised Saliva.

4 c.c. saliva ..	0·0867 grm.	0·3536 grm.	31·83 per cent.
2 „ ..	0·0730 „	0·2984 „	26·72 „
1 „ ..	0·0373 „	0·1560 „	14·04 „

The difference in diastatic action in this instance, particularly where the dilution is as 1:50 and 100, is very great, yet in the case of the greatest dilution of the unneutralised saliva the alkalinity of the digestive mixture is but 0·00091 per cent calculated as alkaline carbonate. Moreover, there is a greater proportional diminution of diastatic action in this case, and also in the next greatest dilution where the amount of alkalinity is 0·00182 per cent, than in the presence of 0·00364 per cent; a fact due either to the greater susceptibility of the ferment to alkaline carbonate in a dilute solution or else to some modifying influence of the larger amount of albuminous matter present, a point which we shall return to later.

Carrying the dilution of the saliva still further we find that the difference between the diastatic action of the neutralised and unneutralised fluid shows itself to the limit of decisive diastatic action.

SERIES VI.

This sample of saliva contained 0·116 per cent of alkali calculated as sodium carbonate. The percentages of starch converted into sugar during 30 minutes at 40° C. alone are given.

Amount of saliva.	Alkali in the 100 c.c. of digestive mixture.	Alkaline saliva.	Neutralised saliva.
1 c.c.	0·00116 p.c.	6·33 p.c.	16·34 p.c.
½	0·00058	2·44	6 62
¼	0·00029	1·54	2·07
1/10	0·00011	trace	result lost
1/20	0·00005	trace	1·25 p.c.

Thus in a dilution of 1:2000 in the case of neutralised saliva, diastatic action is still sufficiently pronounced to convert 1·25 per cent starch into sugar during 30 minutes warming at 40° C.

The above results indicative of such a marked susceptibility of the ferment in a dilute solution to the action of the alkali naturally present in saliva, suggest the possibility of there being a direct connection between the alkalinity of the natural secretion and its diastatic power. While the results already given plainly indicate that very slight changes in the alkalinity, everything else being equal, materially modify the diastatic power of the fluid; still the amount of ferment itself, as well as the amount of proteid matter, may vary in different salivas so much as to counterbalance the direct influence of changes in the alkalinity.

This, the results of our experiments seem to indicate, as we have been unable to trace out any direct connection between the natural variations of alkalinity and diastatic action.*

ANALYSES OF COMMERCIAL FERTILISERS.†

On Phosphoric Acid.

DR. JENKINS, chairman, presented the Report of the Committee on Phosphoric Acid.

As required by the Constitution of the Association, the Committee on Phosphoric Acid herewith presents its Report. The Report covers (1) a brief notice of new analytical methods proposed for determining phosphoric acid; (2) a report of some work done during the past year by the committee and members of the Association; and (3) recommendations for the next year.

Henry Pemberton, jun. (*Journ. of Franklin Institute*, CHEMICAL NEWS, 46, and cited in *Fres. Zeitschr. f. Anal. Chem.*, xxiii., 69), determined phosphoric acid volumetrically. A solution of ammonium molybdate of known strength is added to the phosphate solution till the phosphoric acid is completely removed.

Eighty-nine and five hundred and forty-three one-thousandths grms. of ammonium molybdate are dissolved in 1 litre of water. If necessary to secure a clear solu-

† From the *Proceedings* of the Second Annual Meeting of the Association of Official Agricultural Chemists, at Washington, D.C., September 1, 1885. Edited by Charles W. Dabney, Jun., Ph.D., North Carolina Agricultural Experiment Station, Secretary.

tion, a little ammonia is added before filling up to the litre mark. One c.c. of this standard solution corresponds to 0·003 grm. of P_2O_5, since under the conditions here to be given the yellow precipitate will contain phosphoric acid and molybdic acid in the ratio of 1 : 24.

The P_2O_5 (about 0·1 grm., or at most 0·15 grm.) should be in solution in nitric acid, and free from organic matter and silica.

The concentrated solution, in a beaker of 100 to 125 c.c. capacity, is neutralised as nearly as possible, and to it are then added 2 c.c. of nitric acid, of sp. gr. 1·4, and 10 grains of crystallised ammonium nitrate. The solution is heated to 60° C., and the standard molybdic solution is run in, with constant stirring, till all the P_2O_5 is separated.

To determine this point of complete separation the author, after each addition, filters a small quantity, heats to 60° C., and observes whether adding more of the standard solution produces a further precipitation. From the number of cubic centimetres used 5 c.c. is deducted, that being the amount which experiments have shown is necessary in excess to secure perfect precipitation.

Otto Freiherr von der Pfordten (Inaugural Dissertation, *Fres. Zeitschr. für Analyt. Chem.*, xxiii., 422) proposes a volumetric method for the determination of P_2O_5. He secures the precipitation of ammonium phospho-molybdate without free molybdic acid in it. By zinc and hydrochloric acid he reduces the combined molybdic acid of the precipitate to the suboxide Mo_5O_7, which in the air at once passes into the sesquioxide Mo_2O_3, and then by a standard solution of potassium permanganate he determines the amount of oxygen necessary to oxidise the Mo_2O_3 to molybdic acid. From this the amount of phosphoric acid can be reckoned.

The details of the method are as follows:—Phosphoric acid is precipitated as ammonium phospho-molybdate. Particulars with regard to the precipitation are not given in the abstract, but no doubt the method employed by Pemberton, which has been already described, will answer here. The precipitate is washed out on the filter-pump with a nearly saturated solution of ammonium sulphate, until a drop of the filtrate no longer shows a dark brown colouration when ammonium sulphide is added to it. The precipitate is dissolved in a small quantity of ammonia, the solution is brought to a definite volume, and an aliquot part is taken which should contain not more than 0·3 grm. MoO_3. In any case not more than 30 c.c. should be used, otherwise the solution is too dilute. To this solution in a small flask are added 50 to 60 c.c. 27 per cent HCl, and 8 to 10 grms. of zinc in stick form, whose content of iron has already been determined by titration. When the solution has a yellow colour the flask is cooled before all the zinc is exhausted, and its contents are rinsed into a porcelain dish containing 40 c.c. dilute H_2SO_4, and 20 c.c. of a solution of 200 grms. $MgSO_4$ in 1 litre. The solution is at once diluted with water to 500 c.c., and titrated with a standard solution of potassium permanganate. From the number of cubic centimetres required for oxidation must be deducted the amount used in the oxidation of the iron which may exist as an impurity in the zinc.

Van der Pfordten finds in the yellow precipitate the same relation (1 : 24) between P_2O_5 and MoO_3 that was found by Finkner and H. Pemberton, jun.

The ammonia and water contents of the precipitate are variable.

C. Morh (*Zeitsch. für Anal. Chem.*, xxiii., 487) describes a method for the extraction of "reverted" P_2O_5 by means of an alkaline ammonium-citrate solution, and subsequent determination of the soluble and reverted together by the molybdate method, after oxidising the organic matter with fuming nitric acid. This has at present no special interest for us, since the method of extraction is so entirely different from the one adopted by this Association.

David Lindo (Chemical News, xxxviii., 1884, 247, cited in *Biedermann's Centralblatt fur Ag. Chem.*, 1884, 642), by careful experiments, shows the value of his so-called "oxalate method," which consists in removing CaO as oxalate in a neutral solution of the phosphate, after separating silica, and then precipitating P_2O_5 by magnesia mixture with the addition of some citric acid. The method gives good results even where the iron oxide is present with silica; but if alumina is present with silica the results will come too high.

Lindo also shows that the molybdate method in the presence of *small* amounts of silica will give accurate results, but not if a considerable quantity of SiO_2 is present. In one experiment the presence of 0·008 grm. SiO_2 and 0·04 grm. Al_2O_3 did not interfere with the accuracy of the determination.

J. S. Wells (*Journ. Chem. Soc.*, 1885, 185, papers) proposes a method which is more rapid than the ammonium-molybdate method. He prepares two solutions:—

A contains 900 grms. of citric acid in 500 c.c. of water and 1400 c.c. of ammonia solution, sp. gr. 0·92.

B is a strong solution of magnesium citrate.

One grm. of the fertiliser is fused with 3 to 4 grms. of Na_2CO_3 and 3 to 4 grms. $NaNO_3$. The fused mass is dissolved in nitric acid and filtered. To this phosphate solution is added enough of A to prevent any precipitation of phosphates when the solution is made alkaline. This usually requires about 10 c c.

After making it alkaline the whole is allowed to stand thirty minutes. If any silica separates in that time it is filtered off. Then enough of B is added to precipitate all of the P_2O_5, and, after stirring vigorously and allowing it to stand for some time, the precipitate is filtered and weighed.

The author states with *naiveté* that if the phosphate is not fused too long the silica will remain insoluble, and "care must be taken not to mistake a possible precipitate of magnesic phosphate for one of silica."

John Ruffle (Chemical News, 51, 63) calls attention to the necessity of separating silica in all cases after boiling a phosphate with HCl, before precipitating with magnesia mixture. With the same phosphate he finds differences in some cases of nearly 1 per cent of P_2O_5, depending on whether SiO_2 has or has not been separated. The results come too high when the silica separation is omitted.

(It is not evident whether the "molybdate" method or the so-called "citric method" was used in the experiments reported.)

G. L. Spencer (*Chem. Centr.*, 1884, 445; *Journ. Chem. Soc.*, 1885, 436, abstracts) separates P_2O_5 by silver carbonate, and determines it volumetrically by a solution of uranium acetate; 5 to 20 grms. of the fertiliser are ignited till the ash is white, dissolved in strong HNO_3, diluted, filtered, and washed. By this means the larger part of the iron is separated and the chlorides are decomposed. To an aliquot part of the whole, which should contain from 0·1 to 0·5 grm. P_2O_5, a slight excess of silver carbonate is added, which forms a perfectly insoluble precipitate of silver phosphate. This is boiled with the supernatant liquid, filtered, and washed with boiling water, and then dissolved in a minimum quantity of HNO_3. The silver is thrown down by sodium chloride, the solution is neutralised with Na_2CO_3, and P_2O_5 is determined by uranium acetate.

J. Bougartz (*Arch. Phar.*, 322, 846; *Journ. Chem. Soc.*, 1885, 438, abstracts) states that P_2O_5, either free or combined with potash or soda, may be determined volumetrically by staudard KOH or NaOH, using methyl orange or phenol-phthalein as an indicator.

If KOH is added to a solution of P_2O_5 till the red of methyl orange has changed to pale yellow, RH_2PO_4 is formed (112 parts KOH = 142 parts P_2O_5). If now phenol-phthalein is added, and the titration is continued till the red colour appears, K_2HPO_4 is formed (112 parts K_2O = 142 parts P_2O_5). If H_2SO_4 or HCl is added till the methyl-orange red reappears, the titration may be repeated. If dicalcium phosphate is dissolved in HCl, and KOH is added till methyl orange becomes yellow, the solution then contains KCl, $CaCl_2$, and $CaHPO_4$ (?).

A further addition of the alkali till phenol-phthalein shows red gives tricalcium phosphate, dicalcium phosphate, and K_2HPO_4. $2CaH_4PO_4+6KHO+2CaCl_2=$

$=Ca_3(PO_4)_2+6H_2O+CaHPO_4+K_2HPO_4+4KCl.$

168 parts KOH = 142 parts P_2O_5. If HCl is added, the titration may be repeated as before. In the presence of sufficient $CaCl_2$ monocalcic phosphate is entirely converted into tricalcium phosphate during the titration. 224 parts KOH = 142 parts P_2O_5.

By this method P_2O_5 may be readily estimated in manures:—From the HCl solution iron and alumina are precipitated as phosphates by the addition of ammonia. Aceuc acid is added to dissolve the calcium phosphate, and in a few minutes the precipitate is brought on a filter and washed till the acid reaction has disappeared.

The precipitate is dissolved in HCl and titrated. To the filtrate containing the rest of the P_2O_5 is added a little HCl and an excess of iron, aluminum, and calcium chlorides. It is heated, and the P_2O_5 precipitated by ammonia. The precipitate is brought on a filter, washed with water containing a little KOH, dissolved in HCl, and titrated after adding excess of $CaCl_2$. It is necessary that the organic matter in the fertiliser should be entirely destroyed by calcination or fusion. The standard solution of KOH must be entirely free from alumina and carbonic acid. It is best prepared from $Ba(OH)_2$ and K_2SO_4.

C. Glaser (*Fres. Zeitschr. fur Analyt. Chem.*, xxiv., 178) describes a method depending on the precipitation of P_2O_5 by magnesia mixture in the presence of just enough ammonium citrate to prevent the separation of $Ca_3(PO_4)_2$, and of enough H_2SO_4 to combine with all the lime present.

There are required—

(1.) Magnesia mixture prepared by dissolving 140 grms. $MgSO_4$, 150 grms. $(NH_4)_2SO_4$, and 30 grms. NH_4Cl in 350 c.c. ammonia solution (16 per cent), and 1650 c.c. of water.
(2.) A 50 per cent solution of cttric acid.
(3.) Dilute ammonia, 250 c.c. (16 per cent ammonia solution diluted to 1 litre.
(4.) Dilute H_2SO_4 (100 c.c. of H_2SO_4, 60° B., diluted to 1 litre).

The phosphate solution in a beaker is neutralised until turbid, and just enough citric acid solution is added to make it clear while still distinctly alkaline. This may require 3 c.c., or at most 4 c.c.

When cold the magnesia mixture is added dropwise, with constant stirring, and then ammonia in large excess. After six to eight—better twelve—hours standing the precipitate is filtered, washed with dilute ammonia, and dissolved in H_2SO_4. More magnesia solution is added, and the solution precipitated again with ammonia. The precipitate is filtered, washed, ignited, and weighed. The advantages claimed are rapidity, economy, and ease. The separation of SiO_2 is avoided, and the results are absolutely accurate.

The same author compares the method used by this Association with the "oxalate method," and finds substantial agreement in the case of superphosphates which contain only a small amount of iron.

With natural phosphates and iron phosphates the agreement is not so good. The "oxalate method" used by him consists in bringing the filter and residue from the extraction of soluble P_2O_5 into a beaker, and boiling for ten minutes with 100 c.c. of a solution of ammonium oxalate, which is saturated at ordinary temperatures. The solution is filtered, and the residue washed with hot water.

We come now to the work which has been done during the year by members of the Association.

Last November your Committee sent to eighteen official and commercial chemists two sealed samples of plain acid phosphates, one made from South Carolina rock and one from Navassa rock, and marked "South Carolina" and "Navassa." The material had been air-dried, put through a ½-inch-mesh sieve, and very thoroughly mixed. The Committee requested that determinations should be made, by the method recommended by this Association last year, of the following ingredients:—Water, soluble phosphoric acid, reverted phosphoric acid, and insoluble phosphoric acid.

In response to this request your Committee has received reports from fifteen chemists. The number of laboratories represented is twelve, for in three cases reports were sent from chemists who worked in the same laboratory, presumably with the same reagents, &c.

These reports were received at different dates from December to the last of June. On July 1st the Committee sent to each chemist who had participated in the work a tabulated statement of all the results which had been received. The names of the chemists were not given.

Some brief notice of these results may be in place here:—

(1.) The water determinations were absolutely worthless.

In "South Carolina" different chemists found from 8 to 10·50 per cent moisture; in "Navassa" from 8·65 to 9·85 per cent.

This is to be expected. An accurate water determination in a superphosphate requires more time and care than the determination is generally worth. All superphosphates contain, besides hygroscopic moisture, water in combination with calcium sulphate, produced in their manufacture by the action of sulphuric acid on calcium phosphate. This water cannot be entirely expelled at 100° C., and only very slowly, if at all, at 110° to 120° C. Now if organic matter, such as is present in an ammoniated superphosphate, is heated in air to 110° to 120°, it is more or less oxidised, and thus the accuracy of the determination is impaired.

To illustrate the uncertainty of the determination the following experiment made by the writer with "South Carolina" will suffice:—Five portions, of 1 grm. each, were dried for one, two, three, four, five hours, respectively, in an air-bath at 100° C. The results were as follows:—

Mark.	Dried for—	Loss.
A	1 hour	9·04 per cent.
B	2 hours	8·86 ,,
C	3 ,,	9·21 ,,
D	4 ,,	9·20 ,,
E	5 ,,	8·99 ,,

These results are tolerably uniform, but on continuing the drying the results were as follows:—

	A.	B.	C.	D.	E.
For 6½ hours, total loss—	9·49	9·71	9·59	9·32	9·12
For 6 hours additional, total loss—	9·79	9·77	9·82	9·96	9·67
For 8 hours additional, total loss—	10·02	9·92	10·12	10·15	10·02
For 10 hours additional at 110°, total loss—	Lost	10·29	10·37	10·30	10·07
For 6 hours additional at 110°, total loss—	—	10·39	10·37	10·30	10·27

Here the loss ceased, but if the superphosphate had contained organic matter it is hardly to be expected that the results would have been as uniform.

(To be continued.)

Influence of Acid Ammonium Oxalate upon the Solubility of the Neutral Oxalate.—R. Engel.—The quantity of one of the oxalates in solution diminishes as the other increases. On treating a saturated solution of the neutral oxalate with a little oxalic acid there is precipitated not the acid oxalate, as it is generally assumed, but neutral oxalate.—*Comptes Rendus.*

ON PLATOSO-OXALIC ACID.

By H. G. SÖDERBAUM.

Doebereiner formerly obtained by the action of oxalic acid upon the sodium salt of platinum dioxide a salt of a a copper-red colour which he regarded as platinous oxalate. Souchay and Lenssen assign it the formula $PtNa_2C_4O_8 + 4H_2O$. This salt has much analogy with the platinum sulphites, since the solution gives neither the reactions of platinum nor those of oxalic acid. We may therefore regard this componnd as the sodium salt of platoso-oxalic acid which has been isolated.

The salts of platoso-oxalic acid are very remarkable, because they occur in isomeric or rather polymeric forms.

For the preparation of the sodium salt sodium chloroplatinate is heated with an equal weight of sodium hydrate. The residue is treated with water, which dissolves out sodium chloride, leaving a yellow powder—

$$Na_2O,3PtO_26H_2O.$$

More of it is obtained by the addition of hydrochloric acid to the solution of sodium chloride, avoiding excess. It is washed with cold water and washed with 1½ part of crystalline oxalic acid. Carbonic acid escapes, and there is obtained a solution of an intense blue colour. When cold slender brown needles of a metallic lustre are deposited. This salt is collected upon a filter and repeatedly washed with boiling water. There filters first a yellow solution, then a greenish or blue one, and lastly a solution of a reddish brown. From the last liquid the mass of the sodium salt is deposited on cooling, crystallised in capillary needles of a coppery lustre. The first solution after some time deposits lemon-yellow prisms of an isomeric salt. The intermediate solutions deposit mixtures of the two salts. Both salts yield with silver nitrate a yellowish white precipitate of microscopic crystals of the silver salt of platoso-oxalic acid. On decomposing this silver salt with the calculated proportion of hydrochloric acid we obtain an indigo-blue solution containing platoso-oxalic acid. We may obtain the salts of the acid either by the double decomposition of the sodium salts or by neutralising the free acid with bases or carbonates. With the brown sodium salt there are obtained salts of a brown, greenish, or blue colour; but with the yellow salt we obtain isomeric yellow or orange salts. The free acid generally gives salts of the former class, *i.e.*, of a dark colour, but by repeated crystallisations yellow salts may be obtained. Several metals belonging to the zinc group form dark-coloured salts most readily; others, for instance silver, yield yellow salts, and others again form with equal ease either dark or yellow salts. The tri- and tetra-atomic metals give both dark and yellow salts, but of a different composition. The dark salts are in general less soluble; their density is lower and they often contain a smaller number of mols. of crystalline water. The difference between the two classes of salts does not depend on the water of crystallisation, because both dark and yellow anhydrous salts have been obtained and because there exist both yellow and dark salts containing the same number of mols. of crystalline water.

The salts of platoso-oxalic acid are in general sparingly soluble in cold dilute acids: they are insoluble in alcohol. In hot water some of them dissolve readily; others are sparingly soluble. Most of them contain crystalline water, which they lose in part or entirely at 100°. They bear the temperature of 110° to 115° (though the ammonium salt is decomposed at 100°); but a little above this temperature they begin to decompose. If suddenly heated they are decomposed with detonation.

Platoso-oxalic acid, $PtC_4O_8H_2 + 2H_2O$, the preparation of which has been described above, gives, when its solution has been evaporated in a vacuum, a red crystalline mass of a metallic lustre. It dissolves readily in water with an indigo-blue colour, but this colour changes to yellow on heating or diluting with water. Yet the blue colour returns on cooling or on concentration.

There are two potassium salts, a brown one forming copper-coloured needles of sp. gr. 3·01, and a yellow one in hexagonal prisms of sp. gr. 3·03. Both contain the same number of mols. of crystalline water. With the ammonium salts the case is similar. The dark sodium salt forms slender needles containing 4 mols. crystalline water, whilst the yellow salt forms prisms with 5 mols. of crystalline water. There are three isomeric calcium salts; the brown one with $6\frac{1}{2}H_2O$; the β-yellow salt with $4H_2O$, losing 1 mol. water at 100°; and the γ-yellow salt with $8H_2O$, losing at 100° $5H_2O$. There are also three strontium salts: α, dark, contains $3\frac{1}{2}H_2O$ and loses $\frac{1}{2}H_2O$ at 100°; β, also dark, contains $6\frac{1}{2}H_2O$ and loses $3H_2O$ at 100°; and γ, yellow, contains only 3 mols. of crystalline water and undergoes do change at 100°.

These researches were made in the laboratory of Prof. P. T. Clève.—*Bulletin Soc. Chimique de Paris*, 1886, p. 188.

THIRD REPORT OF THE COMMITTEE*

RE-APPOINTED FOR THE PURPOSE OF DRAWING UP A STATEMENT OF THE

VARIETIES OF CHEMICAL NAMES WHICH HAVE COME INTO USE,

FOR INDICATING THE CAUSES WHICH HAVE LED TO THEIR ADOPTION, AND FOR CONSIDERING WHAT CAN BE DONE TO BRING ABOUT SOME CONVERGENCE OF THE VIEWS ON CHEMICAL NOMENCLATURE OBTAINING AMONG ENGLISH AND FOREIGN CHEMISTS.†

PROCEEDINGS OF SOCIETIES.

PHYSICAL SOCIETY.

February 27th, 1886.

Dr. J. H. Gladstone in the Chair.

The following were elected Members of the Society:—Dr. Sydney Young and Mr. D. E. Jones.

The following communications were read:—

"*The Relations of Pressure, Temperature, and Volume in Saturated Vapours.* By Prof. W. C. Unwin.

In the first part of this paper certain formulæ given by Messrs. Ramsay and Young, in a recent communication on "Some Thermodynamical Relations," are criticised. The most important of these is the statement that for different saturated vapours at the same pressure $p\frac{dp}{dt}$ is constant. Professor Unwin finds, however, that $t\frac{dp}{dt}$ is less constant than $t^2\frac{dp}{dt}$, while $\frac{t^2}{p}\frac{dp}{dt}$ is nearly a constant quantity for all saturated vapours under any conditions. This result suggested that—

$$\frac{t^{n+1}}{p}\frac{dp}{dt}$$

might be more nearly constant, and the integration of this gives—

$$\log. p = a - \frac{b}{t^n}$$

—a formula to the examination of which the second part of the paper is devoted. From it may be derived the following relations, in which, for convenience in calculation, the logarithms given are to the base 10.

$$t = \left(\frac{b}{a - \log. p}\right)^{\frac{1}{n}}$$

$$\frac{1}{p}\frac{dp}{dt} = 2{\cdot}3025\frac{nb}{t^{n+1}}$$

$$= 2{\cdot}3025\, n\frac{(a-\log. p)^{\frac{n+1}{n}}}{b^{\frac{1}{n}}}$$

$$\frac{t}{p}\frac{dp}{dt} - 2{\cdot}3025\frac{nb}{t^n},$$

&c.

These formulæ have been examined in the case of steam from −30° to 230° C., and with pressures varying from 0·4 to 20,000 m.m. The constants were found to be—

$$a = 7{\cdot}5030 \qquad b = 7579 \qquad n = 1{\cdot}25$$

and the differences between the calculated results and the observations of Regnault and Zeuner rarely exceeded 1 per cent, while generally much smaller.

a, b, and n have also been found for some other substances, with the following results:—

Alcohol	$a = 7{\cdot}448$	$b = 8784$	$n = 1{\cdot}29$
Ether	$a = 6{\cdot}9968$	$b = 3047$	$n = 1{\cdot}153$
Mercury	$a = 9{\cdot}8651$	$b = 597{\cdot}5$	$n = 0{\cdot}69$
Carbonic acid ..	$a = 8{\cdot}4625$	$b = 302{\cdot}8$	$n = 0{\cdot}77$

Prof. Perry offered some criticisms upon this paper, and believed that for practical purposes the expressions given would not be found superior to Rankine's formula

$$\log. p = a - \frac{b}{t} - \frac{c}{t^2},$$

which gives p in terms of t, and a quadratic expression for obtaining t in terms of p. He also observed that the chief aim of Ramsay and Young's paper was to obtain relations between the pressure and temperature of different saturated vapours, so that the connection between temperature and pressure having been observed and recorded for one vapour, that for any other vapour could be at once deduced from it.

"*On a Map of the World, in which the Proportion of Areas is preserved.*" By Mr. Walter Baily.

The author has devised a method for constructing such a map, but has subsequently found that one precisely similar was employed by Flamsteed, in 1729, for charting the stars in his "Atlas Cœlestis." The construction applied to the Earth is briefly as follows:—Draw a straight line to represent the meridian that is to occupy the centre of the map. Divide this line into equal parts representing upon a convenient scale the distance between the parallels of latitude, and through these points draw a series of lines at right angles to the original line: these are the parallels of latitude. Mark off on these the actual distances at which the meridians cut them: through the points so found the meridians may be filled in, and the map constructed. From the method of construction it is evident that although the outlines in the map are distorted, the amount of distortion increasing with the distance from the central meridian, the proportionality of areas is preserved, a fact which the author believes will render the map useful for recording rainfall, depths of sea, ocean currents, &c.

"*On a Delicate Calorimetric Thermometer.*" By Prof. S. U. Pickering.

MANCHESTER LITERARY AND PHILOSOPHICAL SOCIETY.

Ordinary Meeting, January 12, 1886.

Prof. W. C. Williamson, LL.D., F.R.S., President, in the chair.

"*Note on a Paper by Dr. T. Leone, 'On the Micro-organisms of Potable Waters, and their Life in Carbonate Waters.'*" By F. J. Faraday, F.L.S.

An interesting paper, by Dr. T. Leone, on the micro-organisms of potable waters, was recently published in the *Gazzetta Chimica Italiana*. A translation appeared in the Chemical News of December 4th last. In fulfilment of a promise to the late Dr. Angus Smith, I propose to comment on some points in this paper which have a bearing on Dr. Smith's researches. Dr. Leone observes: "Many experimentalists who have occupied themselves with the study of microbia on Koch's method, have contented themselves with the summary appreciation of the value of a potable water according to the number of microbia present, capable of producing 'colonies' in gelatin. It is believed that the bacteria derived from putrescent animal matter produce colonies which liquefy gelatin. From the number of such colonies it is believed that we may form an opinion as to the greater or less corruption of a water."

It will be remembered that in his latest *Rivers Pollution Report*, Dr. Smith gave a series of results showing the comparative purity of different waters according to this method. Dr. Leone goes on to say: "Since the majority of such experimentalists have not taken account in such researches of the time which has elapsed from the moment in which the water was obtained to that when it was experimented upon, and since these experimentalists

have ascribed to a water thousands and thousands of microbia per c.c —a water which may have required two or three days' journey from its source to the point where it comes to be examined—it is to be supposed that these experimentalists have disregarded the possibility that the purest drinking-water may be a good medium for the culture of microbia."

As regards the latter part of this passage, I wish to point out that Dr. Smith specially called attention to the fact that very pure spring water contains active microbia. Dr. Smith found that all waters gave off hydrogen when sugar was added, except distilled water and water which has been boiled, which do not give off hydrogen under the conditions specified. Dr. Smith found further that, taking a series of samples ranging from the very pure spring water of the uplands down to the most foul sewage, the quantity of hydrogen given off with sugar was apparently proportionate to the degree of contamination; and he added that, so far as he was aware, there was no water which had not previously been boiled or distilled which did not give evidence of the presence of the micro-organisms in this way. Dr. Smith showed me the proofs of his report containing these statements at the beginning of 1884; and from numerous conversations with him, I am able to say that there is no room for doubt that he was very strongly impressed with the fact that spring waters, which may be regarded as pure, offer a medium for the culture of microbia.

I have looked carefully through his report, however, in order to see if he has given there any indication of having taken into consideration, in his comparative quantitative experiments, the possibility of a considerable multiplication of the microbia during the period between the collection of the water and the application of the test, such multiplication being, of course, irrespective of any further contamination in the interval. I have no recollection of this point having been mentioned in our conversations; but as Dr. Smith was very ill at the time the report was passing through the press, our conversations were not exhaustive. In one or two cases it is stated in the report that the test was applied after the water had been allowed to stand for forty-eight hours subsequent to the collection of the sample; but this was apparently done merely in order to test the deposit, the clear water being syphoned from the top. Whether Dr. Smith took into consideration the self-multiplication of the microbia present in the samples during the different intervals of time required for their transit to his laboratory from various distances, I have not been able to make out. Owing to the unfortunate circumstances of Dr. Smith's long illness and death before the publication of the report, it is possible that matters to which he would have attended under other circumstances may have escaped record or notice. The point is an interesting one, and as some of the members of the Society, or those who assisted him in the experiments, may be able to throw further light upon it, it has appeared to me desirable to bring the matter under the notice of the Society, in order that no fact bearing upon Dr. Smith's latest inquiry, and one which he regarded with great hopefulness, may he lost.

The statements made by Dr. Leone as to the multiplication of microbia in very pure waters are remarkable. Taking the Maugfall water, which supplies the city of Munich, as a type of the purest potable waters, he collected it in vessels very carefully sterilised and protected from contamination. He gives the results of subsequent examination as follows:—"The Maugfall water arrives at Munich with five microbia per c c. After twenty-four hours, being left under the conditions above described, the number of microbia is found to have risen to more than a hundred per c c. In two days the figure reaches 10,500. In three days, 67,000. In four days, 315,000. And on the fifth day there were more than half a million of microbia per c.c."

It would appear from Dr. Leone's further experiments, that the fact of the water being at rest merely has no influence on the multiplication of the microbia. The water was agitated by means of a wheel arrangement, and the same results were obtained. It is further to be noted that, after attaining the maximum, the number of microbia gradually declined, so that a curve would be given by a graphic illustration.

The results obtained by Dr. Smith from his hydrogen test, and by cultivation in gelatin, were approximately the same. *Prima facie*, however, it seems obvious that these results would be affected by the length of time which might have elapsed subsequent to the collection of the samples. We must assume, of course, that multiplication would take place in the spring or stream as in the test-vessels; but the water under natural conditions would be constantly diluted from the source, so that the proportion might never rise much above the minimum. In the test-vessels all the succeeding generations would be retained in the confined space. It seems obvious, therefore, that the comparisons would be affected by the factor of time. Water tested immediately after collection at the spring would apparently give smaller indications of microbe activity than if retained for twenty-four hours or longer. Much, too, would depend on whether the testing took place after the maximum reproduction had been attained, and the curve had taken a downward course.

Dr. Leone experimented also with water saturated with carbonic acid under pressure, and records the result as follows:—"In these researches it was found that whilst in the non-carbonic water the number of microbia rose in five, ten, and fifteen days from hundreds to thousands per c.c., in the carbonic water the number of microbia not only did not increase but it diminished. In five days the number of organisms had fallen from 186 per c.c. to 87; in ten days to 30; and in fifteen days to 20."

Dr. Leone applied other tests and came to the conclusion that the carbonic acid is the sole agent which interferes with the life of organisms in carbonic waters.

One or two inquiries suggest themselves to me in connection with these very interesting observations. In the first place can we safely accept the mere numbers of the microbia as an expression of their chemical activity? Thus, taking Dr. Smith's hydrogen test, the quantity of hydrogen given off is regarded as an indication of the relative impurity of the water. But would a greater evolution of hydrogen be necessarily associated with a greater number of microbia? Pasteur has called attention to a remarkable peculiarity in the life-history of microbia, observed during his experiments with the beer ferment. In the case of all other living creatures the weight of nutritive matter assimilated is proportionate to the weight of food consumed. In the case of alcoholic fermentations, however, the quantity of yeast formed is not proportionate to the quantity of sugar decomposed, but varies according to other conditions, noticeably the abundance of free oxygen. Thus for *a* of yeast formed the weight of sugar decomposed in the process may be 10*a*, 20*a*, 100*a*, or even more. Much depends in this respect. M. Pasteur argues, upon whether the yeast—or the microbe—has the vigour of youth or the decrepitude of senility. The cells of yeast, he tells us, in order to multiply in a fermentable medium in the absence of free oxygen, must be young and full of life and health; if older, they have much difficulty in reproducing themselves in a *milieu* deprived of free oxygen. For the reasons already given, therefore, it would appear that the mere quantity of microbia reproduced in a given time may not be a test of the relatively innocuous character of the water or of the chemical activity of the organisms present. The quantity of hydrogen given off would apparently be a test of the latter, and it seems not improbable that, at least in some cases, the pathogenic virulence of microbia may be proportionate to the chemical activity set up rather than to the productive activity. The inquiry suggests what is, to me, a rather startling thought, and that is whether we may not arrive at a method of treating zymotic diseases by actually feeding the specific microbia, or, in other words, supplying them with appropriate means

of existence, and thus diminishing their pathologically destructive action. If we follow out this line of reasoning it does not appear to follow necessarily that because, according to Dr. Leone, carbonic acid interferes with the life of organisms in water, or, in other words, arrests their multiplication, therefore it is a hygienic agent. Much must depend on the character of the organisms. Such a condition may simply eliminate the weaker or older organisms, and even accumulate their vital energy in those which remain. In dealing with this mysterious field of research, where there is still so much to tempt the investigator, I may, I hope, be pardoned for asking whether under certain circumstances a quantitative diminution of the microbia may not be consistent with a qualitative increase in regard to the capacity of the remainder for work?

NOTICES OF BOOKS.

The Artists' Manual of Pigments: showing their Composition, Conditions of Permanency, Non-Permanency, and Adulterations; Effects in Combination with Each Other and with Vehicles; and the most reliable Tests of Purity. By H. C. Standage. London: Crosby Lockwood and Co.

The artist, like the dyer or tissue-printer, should be a chemist. He has to be well acquainted with the nature of colouring-matters, their behaviour with air and light, with each other, and with the mediums or vehicles employed. If he neglects these questions, then, however admirable may be his works, both in conception and execution, they will prove fugitive, and posterity, gazing at some discoloured picture, will turn away disappointed. Mr. Standage refers, in his Preface, to the deterioration of the hues of modern paintings, and especially English paintings, in comparison with the worke of the old masters. This change for the worse, this progress in the wrong direction, he ascribes to "the ignorance of the modern artist as regards the actual nature of the materials he employs." Strange and sad that, in spite of the development and the diffusion of chemical knowledge, our modern artists should have a less practical acquaintance with colours than had their predecessors. He thinks that the supply of ill-made and adulterated pigments is greatly encouraged by the "huge host of amateur painters and manufacturers of 'pot-boilers' who have no name to lose by bad workmanship."

Mr. Standage begins his survey of colours with baryta-white, known also as constant or permanent white, or as "blanc fixe." This compound, he tells us, "consists of 137 equivalents of barium, 32 equivalents of sulphur, and 64 equivalents of oxygen." This is a misuse of the term equivalent. Barium sulphate consists of 1 atom of barium, 4 atoms of oxygen, and 1 atom of sulphur, or 137 parts by weight—not equivalents—of barium, 64 of oxygen, and 32 of sulphur. For the detection of free sulphuric acid in barium sulphate—a perfectly unpardonable impurity—he recommends to "add a few fragments of loaf-sugar to a largely diluted solution (?) of the pigment, and evaporate to dryness. A black charred residue indicates free sulphuric acid." A simpler process is to stir up with distilled water, and to test with blue litmus. If there is the slightest reddening the sample ought to be rejected.

Sap-green, it appears, is adulterated with the extract of raw coffee-berries (caffeo-viridic acid),—a good colour for confectionery, but worthless either for the painter or the dyer.

Guignet's green is described as the best and most permanent green of the palette, which is unaffected by light, damp, or impure air, and is neither injured by nor injures other pigments.

We find it stated that certain colours are injured by darkness. This curious fact can be explained only by the circumstance that they are liable to spontaneous decompositions which light prevents or retards.

Under "Cæruleum" we find what is most probably a clerical error. It is said to be a "stannate of cobalt," artificially made of "carbonate of copper 15 parts, powdered flint 20 parts, and copper 3." This mixture contains neither tin nor cobalt, and must yield a copper silicate.

Under "Indigo" we read:—"The best indigo will swim upon water, and is lightest, brightest, and most copper-coloured, and most fine grain and inodorous." Heavy indigoes are assuredly bad, but light ones may be poor if they have been sophisticated with starch, or if the colouring-matter is poorly developed.

Under "Carmine Lake" the author forgets that it may be adulterated with a lake of aniline scarlet, which dissolves in dilute ammonia, as does the genuine colour.

The chapter on the "Chemical Reactions between two or more Pigments, or between Pigment and Vehicle," is calculated to prove of great use to artists. Certain pigments, safe and permanent *per se*, become fugitive and work mischief if mixed together. Mr. Standage is not at all too rigorous in viewing all lead pigments with distrust.

Ammoniacal fumes are justly mentioned as destructive to paintings, and those of coal-gas—*i.e.*, sulphurous acid passing into sulphuric acid at the expense of atmospheric moisture—should not be forgotten. A picture has a much poorer prospect of long life in the atmosphere of London than it would have had in that of ancient Athens or mediæval Florence.

Space does not allow us to extend our remarks on this useful little book any further. We must say, however, that we are not gratified to find a string of "Examination Questions" as set by the Science and Art Department.

CHEMICAL NOTICES FROM FOREIGN SOURCES.

Note.—All degrees of temperature are Centigrade unless otherwise expressed.

Comptes Rendus Hebdomadaires des Séances, de l'Académie des Sciences. Vol. cii., No. 7, February 15, 1886.

Death of the Perpetual Secretary M. Jules Jamin.—This issue opens with the discourses pronounced at the funeral of this distinguished physicist by MM. J. Bertrand and L. Troost.

Electrolysis of Salts.—Adolphe Renard.—In dilute solutions the quantity of metal precipitated increases proportionally to the temperature. If the distance between the electrodes is successively doubled the quantity of metal precipitated decreases in a geometrical progression. From the results obtained it appears that when the two electrodes are identical the quantities of the metal precipitated are proportional to their diameters, and consequently to the square root of their surfaces.

Observations on a Memoir by M. A. Millot on the "Oxidation-Products of Charcoal by the Electrolysis of an Ammoniacal Solution."—A. Bartoli and G. Papasogli.—M. Millot affirmed in a memoir (*Comptes Rendus*, Aug. 10, 1885) that no mellic acid was found in the ammoniacal solution electrolysed. The authors reply that if he failed to find mellic acid in the ammoniacal liquid and mellogen in the black matter he must have experimented under different conditions from them.

A Compound of Acetic Ether and Magnesium Chloride.—J. Allain-le-Canu.—Acetic ether forms a definite compound with magnesium chloride just as it does with calcium chloride, but the desiccation of the crystals formed is in the former case still more difficu

Strontium and barium chlorides are absolutely insoluble in acetic ether. Zinc chloride dissolves freely with a great liberation of heat.

The γ-Bromo- and Iodo-butyric Acids.—L. Henry.—The γ-bromo-butyric acid crystallises in rhomboidal plates or tablets perfectly white and permanent in the air. It is more soluble in water than the corresponding iodo-compound and dissolves easily in ether and carbon disulphide. It melts at 32° to 33°. The γ-iodo-butyric acid forms crystalline lamellæ, which turn yellow on exposure to the air and melt at 40° to 41°.

Berichte der Deutschen Chemischen Gesellschaft zu Berlin, Vol. xix., No. 1.

Ortho-nitroglycines and their Reduction Products.—J. Plöchl.—An account of ortho-nitro-phenylglycine, oxydihydro-quinoxaline, ortho-nitro-tolylglycine, and oxydihydro-toluquinoxaline.

Contributions to the Knowledge of Carvacrol and its Derivatives.—S. Lustig.—Carvacrol (oxycymol) occurs præ-formed in the ethereal oil of *Satureia hortensis* and in the oils of origanum. To a small extent it is found in the oil of *Thymus serpyllum* along with its isomer thymol. The author discusses carvacrol-sodium, ethyl- and benzoyl-carvacrols, acetyl-carvacrol, the action of chloroform and sodium hydroxide in aqueous solution upon carvacrol, and the oxidation of carvacrotin-aldehyd by potassium permanganate.

Action of Carbon Oxychloride upon Copper Acet-acetic Ester.—MM. Conrad and Guthzeit.—Not adapted for useful abstraction.

New Quinon-derivatives from Succinylosuccinic Ether.—A. Hantzsch and K. Loewy.—The author has obtained and examined dioxyquinon-dicarbonic ether and its derivatives.

Ammonium Derivatiues of the Acid Ethers of Pyridin and Quinoline.—A. Hantzsch.—.—In contrast to the ammonium compounds of all the pyridin-carbonic ethers hitherto examined, which are readily saponifiable, the chlor- or iod-methylate of this quinoline-carbonic ether energetically resists this action. Nor was it possible to split up the ammonium base by strong sulphuric or hydrochloric acid into acetic acid and methyl-pseudo-carbostyril. It remains either undecomposed or yields humoid products.

Action of Acetophenon upon Ammonia.—C. Engler and P. Riehm.—The authors obtain by this reaction a base which is a pyridin derivative.

Action of Chlorolevulic Ester upon Sodium-malonic Ester.—MM. Conrad and Guthzeit.—The product of this reaction is α-carboxyl-β-acetyl-glutaric acid. The authors have examined the zinc, barium, and silver salts of this nsw compound.

Ammonia as a Reagent for Double Ketones of the Position 1 : 4.—L. Knorr.—The author dissolves a small portion of the substance in question in glacial acetic acid, adds a solution of ammonia in an excess of acetic acid, boils the mixture for half a minute, adds dilute sulphuric acid and boils again, introducing a splinter of pine wood into the solution. An intense reddening of the splinter shows the presence of a double ketone of the position 1 : 4.

On Glucosamine.—F. Tiemann.—The author has obtained phenylglucosazon from glucosamine hydrochlorate, examined glucosamine hydrobromate, and determined the specific rotatory power of glucosamine hydrochlorate.

Action of Hypochlorous Acid upon Chinoline Derivatives.—Alfred Einhorn and R. Lauch.—If chinolin is added to a clear filtered solution of hypochlorous acid, obtained by mixing an aqueous solution of chloride of lime with an excess of boric acid, there is a considerable development of heat, which is moderated by refrigeration. Basic calcium borate is deposited, and in the resinous mass resulting from the reaction there occurs carbostyril along with unchanged chinolin.

On the Isomeric α-Naphthylamin Sulpho-acids. Otto N. Witt.—The author describes Piria's naphthionic acid and has obtained its copper salt (the existence of which was questioned by Piria) as a white crystalline salt. He then describes the acid of Nevile and Winther, which he finds to be a homogenous compound. Lastly he has prepared and examined an acid by the reaction of naphthylamine and an excess of sulphuric acid.

On Wrightine.—H. Warnecke.—This alkaloid, first isolated by Stenhouse in 1861, from the seeds of *Wrightia antidysenterica*, an apocynaceous tree from India. It is the first-known solid base occurring in nature which is free from oxygen. If a trace of this base, dissolved in chloroform, is evaporated to dryness in a porcelain capsule, the residue covered with 2 to 3 c.c. of water, and strong sulphuric acid is added in a slender stream, a golden-yellow colour spreads from the bottom of the capsule through the whole liquid, and turns to a green on standing for 12 hours. If 1 m.g. of the alkaloid is rubbed up in a watch-glass with 5 drops of strong sulphuric acid and let stand exposed to the air for 2 hours, the liquid, which was at first colourless, turns yellowish-green, and finally a pale violet. It the above mixture is at once exposed in the neck of a flask to the steam of boiling water the mass turns dark green, and passes into deep blue on contact with a little water.

Bulletin de la Société Chimique de Paris. Vol. xlv., No. 4, February 20, 1886.

Essays on Fatty Matters: Cacao Butter.—Ch. Du Bois and L. Padé.—Cacao butter melts at 26·8° after an hour's solidification, at 27·4° after 24 hours, at 30·2° after 48 hours, and at 32° after 72 hours. This last point varies no more after a month. The mean density of cacao butter at 18° is 0·980.

Reclamation of Priority on Dioxy-ethyl-methylene.—W. H. Greene.—The author described the properties of this compound some years ago (*Comptes Rendus*, lxxxix., p. 1007). M. L. Pratesi re-discovered the same compound in 1883 (*Gaz. Chim. Ital.*, xiii., p. 313). Quite recently M. Louis Henry has announced (*Comptes Rendus*, ci., p. 599) the preparation of biethyl-oxylated methane by the reaction of sodium ethylate upon methylene iodide, but the density which he ascribes to this body (0·8275) and the boiling-point (82° to 83°) seem to indicate that the compound which he obtained was not pure.

On a New Synthesis of an Inactive Borneol.—G. Bouchardat and J. Lafont.—Already noticed.

Transformation of Oil of Turpentine into Active Terpilene.—G. Bouchardat and J. Lafont.—Already noticed.

Determination of Chrome.—H. Vidal.—Reserved for insertion in full.

Russian Chemical Society.—Session Dec. 13/27, 1884.

N. Menschoutkine made a communication on the isomerism of the hydrocarbons according to the theory of substitutions.

F. Bevade sent in a research on the precipitation of the carbonates of the earthy alkaline metals by the alkaline carbonates, with reference to the duration of the reaction, to the masses, and to the nature of the bodies brought into contact.

N. Socoloff presented the results of his analyses of the water of the Neva during 1883-84.

V. Alexeeff pointed out, with reference to the isomerism of solutions, that the presence of a point of transition in these phenomena could only be explained by admitting that bodies might be dissolved either whilst remaining in the solid state, or whilst passing previously into the liquid state.

M. Pospekhoff had studied the reduction-products of nitrocumine, obtaining yellow azocumine, fusible at 112° to 113°, and then becoming volatilised, and hydrazocumine, colourless and melting at 65°.

M. Volodkevitch observed, on heating β-naphthylamine with lead oxide, the formation of crystalline needles, apparently Dehr's azonaphthaline.

P. Alexeeff has studied the action of light upon nitrocuminic acid, which he thinks is by this agency transformed into a true colouring-matter.

E. Wroblewski remarked that the decomposition of the diazo-compounds by alcohol, followed by the formation of the corresponding ethers of the phenols, was indicated in his memoir published in the *Zeitschrift für Chemie*, (new series, vol. vi., p. 164).

G. Wachtel explained the results of his study on the manufacture of potassium dichromate.

MM. Gorboff and Kessler exhibited an apparatus for fractionated distillations at low pressures.

J. Barzilowsky sent in remarks on the oxidation of the aromatic amines.

Session January 3/15, 1885.

M. Butleroff made some remarks on Menschutkin's memoir concerning the isomerism of the hydrocarbides according to the theory of substitutions.

G. Gustavson communicated thermic data for the combinations of aluminium bromide with the hydrocarbons.

M. Pavloff brought forward facts serving to establish the empirical composition and the molecular formula of tetric acid.

M. Chechoukoff described a method of separating the butylenes prepared according to the method of Puchot.

M. Alexeeff has studied the vapour tension of solutions with a view of determining the relations between the composition of these vapours, their tension, and their other properties.

The first number of the Society's *Journal* contains also memoirs "On the Preparation of Hemine," by M. Schalfeeff; "On the Crystalline Form of Hemine," by M. Legorio; "On Diallyl," by A. Sabaneeff; and "On Heptanaphthene," by P. Milkowsky.

Session February 7/19, 1885.

A. Krakau mentioned some accuracies in the deduction of the number of the isomeric derivatives of the benzol series, according to the theory of substitutions.

M. Menschutkine proposed an examination in detail of these remarks.

M. Kaiander presented a remark concerning Menschutkine's memoir on the isomerism of substitutions.

M. Butleroff read a memoir on chemical structure and the theory of substitutions.

M. Menschutkine answered, promising to return to this question.

M. Mendelejeff summed up briefly the history of the question under discussion. He pointed out the want of precision from the mechanical point of view of the distinction between the atomic bonds and the influence of the elementary atoms upon each other, and discussed finally the question of the atomicity of the elements.

The second part of the Society's Journal contained further a memoir, by E. Schatzky, on diallyloxalic acid.

Swedish Correspondence.—By P. T. Cleve.—This correspondence contains a paper, by K. Arnell, on the action of sulphuric acid upon monochlorised naphthaline; a memoir, by J. E. Alen, on α-oxazonaphthaline α-sulphurous acid; a paper, by J. A. Bladin, on the action of cyanogen upon phenyl-hydrazine, which will be inserted in full; a paper, by P. T. Cleve, on the action of benzaldehyde upon hydrazobenzol, in which there is formation of azobenzol, the hydrazobenzol thus appearing to act as a reducing agent. On adding to the mixture zinc chloride, benzylidene-benzidine is produced.

On Platoso-oxalic Acid.—H. G. Söderbaun.—This memoir will be found inserted in full.

MEETINGS FOR THE WEEK.

MONDAY, March 8.—London Institution, 5.
—— Medical, 8.30.
—— Society of Arts, 8. (Cantor Lectures). "Petroleum and its Products," by Boverton Redwood, F.C.S.
TUESDAY, 9th.—Institution of Civil Engineers, 8
—— Royal Medical and Chirurgical, 8.
—— Photographic, 8.
—— Royal Institution, 3. "The Function of Circulation," by Prof. Arthur Gamgee, F.R.S.
WEDNESDAY, 10th.—Society of Arts, 8. "The Experiments with Lighthouse Illuminants at the South Foreland," by E. Price Edwards.
—— Geological, 8.
—— Pharmaceutical, 8.
—— Microscopical, 8.
THURSDAY, 11th.—Royal, 4.30.
—— Royal Society Club, 6.30.
—— London Institution 7.
—— Royal Institution, 3. "The Ancient Geography of Britain," by Prof. W. Boyd Dawkins, F.R.S.
—— Society of Arts, 8. "Films and Paper as Substitutes for Glass in Photography," by Leon Warnerke.
—— Mathematical, 8.
FRIDAY, 12th.—Royal Institution, 9. "The Discovery of the Biblica Cities of Egypt," by R. S. Poole, LL.D.
—— Astronomical, 8.
—— Quekett Club, 8.
SATURDAY, 13th.—Royal Institution, 3. "The Nature and Protective Use of Colour in Caterpillars," by Edward B. Poulton, M.A.
—— Physical, 3. "On the Growth of Filiform Silver," Dr. Gladstone, F.R.S "Apparatus for Measuring the Electrical Resistance of Liquids," Professor Reinold, F.R.S.

TO CORRESPONDENTS.

Baxter Davenant.—You should refer to a good work on "Soap Making." See the one by A. Wall reviewed in our columns (vol. lii., p. 199, No. 1351).

CHEMICAL MANURE AND SULPHURIC ACID WORKS.

TO BE SOLD by Public Roup, within Dowell's Rooms, 18, George Street, Edinburgh, on Wednesday, 24th March, 1886, at 3 o'clock p.m. (unless previously sold by private bargain).

Chemical Manure and Sulphuric Acid Works, presently carried on by Hume Brothers and Company, Limited, at Bo'ness, Linlithgowshire, these extensive Works, which are in good going order, are well situated, and adapted for carrying on Manure Manufacturing. They lie close by the New Dock at Bo'ness and are connected therewith by railway sidings which run through the Works. Vessels of over 2000 tons burthen can be discharged in the Bo'ness Dock, which is fitted with the newest hydraulic machinery. A large sum has been spent on the fixed Plant at the Works, the greater part of which has been erected within the past three years, and the Mills, Engines, and other Machinery are all of the best description and in first-class order. The Furnaces, Acid Towers, and Acid Chambers are likewise in good order.

A comfortable Dwelling-house or Works-foreman, Laboratory Workshops, and convenient Offices are within the ground.

The whole ground, which extends to about 2 acres, 1 rood, 36 poles, 24 yards, is held upon a long lease, 86 years of which have yet to run. The ground rent is £39 13s. 7d. per annum.

For further particulars apply to Mr. James McGown, Manager, at Bo'ness; or, to Davidson and Syme, W.S., 21, Castle Street Edinburgh, who have the title deeds and articles of roup.

VOL. LIII. No. 1372.

COLOUR PHOTOMETRY.*

By Captain ABNEY, R.E., F.R.S., and Major-General FESTING, R.E.

ONE of the authors of this paper has already communicated to the Physical Society of London (*Phil. Mag.*, 1885) a method by which a patch of monochromatic light could be thrown on a screen. This formed the starting point of the present investigation, which was to ascertain whether it was practicable to compare with each other the intensity of lights of different colours.

The authors describe various plans they adopted to effect this purpose, and finally found that by placing a rod in front of the patch of monochromatic light, and of a candle by casting another shadow, the intensities of the two lights could be compared by what they term an oscillation method. It is known that on each side of the yellow of the spectrum the luminosity more or less rapidly decreases. By placing a candle at such a distance from the screen that the luminosity of the two shadows appears as approximately equal, it is easy to oscillate the card carrying the slit through which the monochromatic rays of the spectrum pass. (The slit is in the focus of the lens which helps to form the spectrum.) The shadow of the rod cast by the candle can thus be made to appear alternately "too light" or "too dark" in comparison with the shadow of the rod cast by the parts of the spectrum falling on the screen. By a rapid oscillation the position of equality of the two shadows can be distinguished with great exactness. The authors describe their method of fixing the position of the rays employed and the source of light with which the spectrum is formed. They also enter into details as to the comparison light, the receiving screen, and the comparative value of the light as seen by them respectively. The curve of the intensity of the arc light spectrum, as seen by their eyes, which they call the normal curve, is then described. The question as to the effect of an alteration of the colour of the comparison light is then discussed, as is the effect of the brightness of the spectrum.

The next point touched upon is as to the value of mixed light as compared with its components. It is found that the following law holds good, viz.: *that "the sum of the intensities of two or more colours is equal to the intensity of the same rays when mixed."* This law is applied to Hering's theory of colour.

The authors next state that with the majority of people the curve of luminosity of the spectrum is identical with the normal curve, but that in some cases slight differences may be observed, of which one example is given. Such slight deficiency does not constitute colour-blindness, since the want of appreciation of any colour is but very partial. They next describe observations made by four colour-blind persons, and show that there is a remarkable divergence in their curves from the normal. The deficiency curves are shown, from which it appears that two of the observers are totally blind to red, whilst the other two are partially so. They then show that such observers would not give a true value for any light which is not of identically the same colour as the comparison light they might employ. It also appears that the intensity of illumination felt by a colour-blind is really less than that perceived by a normal-eyed person.

Two examples of the normal curve for sunlight are then given, one taken on a day in July by the method of separating close lines by means of varying illumination, and the other in November, by the method adopted by the authors. Their results are compared with Vierordt's curve, obtained by extinguishing colour with white light.

In order to ascertain the effect of the turbidity of a medium through which light passes (for instance sunlight) the authors compared the intensity of the spectrum after passing through clear water and turbid water, and found that the absorption agreed with Lord Rayleigh's theoretical deductions that $I' = I_0 \varepsilon^{-kx\lambda^{-4}}$, where I' is the intensity after passing through a turbid medium, I_0 the intensity after passing through clear water, x the thickness of the turbid layer, k a constant independent of λ, λ being the wave length.

The authors conclude their paper with a discussion of the intensity of incandescence of carbon electrically heated.

* Abstract of the Bakerian Lecture delivered before the Royal Society March 4, 1886.

ON THE EQUIVALENT OF THE TERBIUMS.

By M. LECOQ DE BOISBAUDRAN.

IT has not yet been found practicable to separate completely from terbia all the other known earths. These latter are always present in very notable quantity, and often form the major part of the total mass. Consequently the equivalents found for various specimens of terbia vary considerably.

Prolonged fractionations, effected at first with ammonia and then with potassium sulphate, have enabled the author to prepare a yellow earth very perceptibly darker than any of those which he has had the opportunity of seeing previously.* This deep-coloured body contains mere insignificant traces of the foreign bodies formerly known, except holmium, the proportion of which, however, is small. We cannot, however, regard this earth as homogeneous, even if we disregard its small admixture of holmium, for it gives very fine spectra of $Z\alpha$ and $Z\gamma$ (the non-identity of which is not demonstrated), which do not seem to belong to the deep earth, since they are more developed at the opposite extremity of the fractionation by potassium sulphate where the oxides are much less coloured. As for the fluorescence $Z\beta$, as it is most brilliant in the deepest coloured earth, we cannot affirm that it indicates the presence of a heterogeneous element. The question of the identity of $Z\beta$ and of Tr remains, therefore, open, but the author observes that this fluorescence, $Z\beta$, is still very fine with earths but slightly coloured.

The equivalent of the deep-coloured earth (composed of $Z\beta$-Tr, $Z\alpha$-$Z\gamma$, and a small quantity of Ho with traces of erbium and samarium) is a little higher than those of the various terbiums prepared by the authors whose memoirs M. de Boisbaudran has been able to consult.

It must be remarked that all the former specimens of terbia which the author has been able to examine spectrally contain large proportions of the $Y\alpha$ of M. de Marignac, and of holmium and also of yttrium and samarium. The equivalents of $Y\alpha$, Sm, and especially of Yt, being relatively low, have naturally tended to reduce the equivalents of the terbiums containing these bodies.

The equivalents have been determined by the method of anhydrous sulphates. Each value is the mean of several fairly concordant numbers. The experiments have been made upon portions of the earth varying from 0·2 to 0·7 grm. for the equivalents, and upon 0·04 to 0·06 grm. for the determination of the oxygen in excess over formula M_2O_3.

The author's darkest earth has a superoxidation rather variable (like its colour) according to the manner in which

* The author here adds the following note:—M. Delafontaine announces that he has prepared a deep orange-yellow terbia, but the equivalent of this earth was 114, a value which he considers as a minimum.

	No. I. Impure Terbia from Gadolinite. Equiv. = 115.	No. II. Terbia from Samarskite. Equiv. = 122·3.	No. III. Terbia prepared by M. Clève. Equiv. = 117·7.	No. IV. Author's palest Terbia. Equiv. = 123·6 minimum.	No. V. Author's darkest Terbia. Equiv. = 124·7 minimum.	
Colour of earths.	Very pale.	Medium, darker than No. I.	Tolerably dark.	Pale, a little paler than No. I.	Dark.	
Absorption.	Decided.	Decided.	Decided.	Much more than in No. V.	Very slight.	Ho.
	Very distinct, but much less abundant than Ho.	Slight, but more than in III. and V.	Slight traces.	Moderate, but much more than No. V.	Very slight traces.	Er.
	Slight.	Nil.	Distinct.	Nil.	Very slight traces.	Sm.
	Very slight.	Nil.	Nil, or very slight.	Nil.	Nil.	Di.
Direct spark. Hydrochloric solns.	Distinct.	Nil.	Nil.	Slight traces.	Nil.	Yt.
	Strong, rather more than No. 2.	Very distinct, more than No. III.	Very distinct.	Nil.	Nil.	Yα.
	Very distinct, but less than No. II.	Very distinct.	Not determined.	Very distinct, more than No. V.	Very distinct.	Zγ.
Fluorescences of the hydrochloric solns.	Very distinct, slighter than in No. II., but not sufficiently determined.	Distinct, but not sufficiently determined.	Very moderate, but insufficiently determined.	Strong, decidedly more than is No. V.	Very distinct.	Zα.
	Strong.	Strong.	Strong, but rather less than in No. IV.	Strong, but decidedly less than No. V.	Very strong.	Zβ.

the calcination has been effected. This superoxidation in the samples employed for determining the equivalents has been found from 0·71 to 0·69 per cent of the earth, or in the mean 0·70 per cent.

Deducting this excess of oxygen from the weight of the crude earth we arrive at the following equivalents for the earth of the formula M_2O_3 ($M\frac{4}{3}O$):—

Darkest earth, equiv. = 125·2. In conditions where the number obtained was certainly a maximum.

Darkest earth, equiv. = 124·7. In conditions where the number obtained was probably a little too low.

This would bring the mean atomic weight of the metals of the darkest earth to at least 163·1.

For other terbias, rather less deeply coloured than the author's, we have:—

Terbia from gadolinite, still impure 115
" " samarskite .. .. 122·3
" " an unknown source, prepared by M. Clève .. .. 117·7

The author's palest earth (fractionated by potassium sulphate) gave an excess of 0·12 to 0·16 in excess above M_2O_3, or as a mean 0·14 per cent, deducting this oxygen from the weight of the crude earth, we have the equivalents:—

Palest earth, equiv. = 124·1. Number certainly a maximum.

Palest earth, equiv. = 123·6. Number probably a little too low.

This would bring the mean atomic weight of the metals of the palest earth to at least 161·4.

The Table above is the result of spectral analysis applied to the various terbias.

The author adds in a note that the terbia No. III. had been placed in his hands for spectroscopic examination but had been returned to M. Clève. He has, therefore, not been able to compare directly the fluorescence of the terbia No. III. with the fluorescences of his more recent products, which would have been necessary for the exact determination of the relative intensity of these spectra. This terbia of M. Clève's, though still containing in particular holmium, samarium, and Yα is still freer from foreign matters already known than any specimen examined prior to the preparation of the dark-coloured earth No. V. Still its equivalent is very low and corresponds only to a mean atomic weight of 152·5.—*Comptes Rendus* (cii., p. 395).

THE DIASTATIC ACTION OF SALIVA, AS MODIFIED BY VARIOUS CONDITIONS, STUDIED QUANTITATIVELY.*

By R. H. CHITTENDEN and HERBERT E. SMITH.

(Continued from p. 111.)

Influence of different percentages of Sodium Carbonate on the Diastatic Action of Saliva.

In 1882, while studying the influence of peptones on the diastatic action of alkaline saliva,† data where then obtained showing a constant diminution of diastatic action in the presence of the alkaline carbonate: the conversion of starch into sugar being diminished in proportion as the percentage of alkali was increased. The digestions at 40° C. were then continued for 45 minutes and the ptyalin was present in large amount, 25 of the 100 c.c. of digestive mixture being undiluted, unneutralised saliva, thus making a very powerful diastatic fluid. We give the data then obtained in the percentage of starch or glycogen converted into sugar.

a. Influence of 0·05 per cent Sodium Carbonate.

	Saliva alone.	Saliva + Na_2Co_3 = 0·15 p.c.	Difference.
Glycogen	28·68 p.c.	20·20 p.c.	8·48 p.c.

b. Influence of 0·15 per cent Sodium Carbonate.‡

	Saliva alone.	Saliva + Na_2Co_3 = 0·05 p.c.	Difference.
Starch ..	40·23 p.c.	17·48 p.c.	22·75 p.c.
" ..	37·15	14·72	22·43
" ..	37·55	15·48	22·07
" ..	38·36	13·57	24·79
Glycogen	28·68	9·40	

* From *Transactions Connecticut Academy*, vol. vi., March, 1886.
† Chittenden and Ely, *Amer. Chem. Jour.*, iv., 121.
‡ The alkalinity is somewhat greater, owing to the unneutralised alkali of the saliva.

c. Influence of 0·30 per cent Sodium Carbonate.

	Saliva alone.	Saliva + Na_2Co_3 = 0·30 p.c.	Difference.
Starch ..	40·27 p.c.	10·83 p.c.	29·44 p.c.
„ ..	40·23	9·87	30·36
„ ..	37·15	9·52	27·63
„ ..	38·80	9·79	29·01
„ ..	37·55	10 01	27·54
„ ..	38·36	9·60	28·76
Glycogen	29·11	6·93	

The action of the sodium carbonate is here very marked and very constant.

We have repeated this series of experiments in part, varying the conditions only by using neutralised saliva, so that the percentages of alkali present might be exact.*

SERIES VIII.

Per cent Na_2Co_3.	Starch converted.	Difference.
0	41·16 per cent.	
0·005	39·47	1·69 per cent
0·025	34·84	6·32
0·050	29·81	11·35
0·150	17·88	23·28
0·300	10·88	30·28

It is evident from these results that the presence of a definite percentage of sodium carbonate will produce approximately a constant diminution in the diastatic action of the saliva. This result, however, is constant only when the saliva acts in the above dilution. Diminish the amount of ferment—or rather dilute the saliva—and then the above percentages of alkali produce quite a different result. The above results were obtained where the dilution of the saliva was as 1 : 4. Adding now neutralised saliva to the alkaline mixtures of starch and water in such proportion that 10 c.c. of the original saliva are present in 100 c.c of digestive mixture, *i.e.*, a dilution of 1 : 10, the results are different.

The following figures were obtained with the above dilution, the mixtures being warmed at 40° C. for 30 minutes.

SERIES IX.

Per cent Na_2Co_3.	Wt. Cu in one-eighth.	Total amt. sugar formed.
0	0·0998 grm.	0·4064 grm.
0·005	0·0898	0·3664
0·025	0·0437	0·1816
0·050	0·0277	0·1184
0·100	0·0182	0·0808
0·300	0·0105	0·0504
0·500	0·0091	0·0448

These figures lead to the following percentages of starch converted into sugar under the different degrees of alkalinity.

Per cent Na_2Co_3.	Starch converted.	Difference.
0	36·57 per cent	
0·005	32·98	3·59 per cent.
0·025	16·35	20·22
0·050	10·66	25·91
0·100	7·27	29·30
0·300	4·53	32·04
0·500	4·03	32·54

By comparing the two preceding columns of differences it is very manifest that the alkaline carbonate has a much greater retarding action on the more dilute saliva than on the stronger solution; very noticeably so in the mixtures containing 0·025 and 0·050 per cent of the alkaline salt.

By diluting neutralised saliva still more, and then using quantities of the fluid equal to 2 c.c. of the original saliva, making in the 100 c.c. of digestive mixture a dilution of 1 : 50, even 0·005 per cent of sodium carbonate is sufficient to retard the diastatic action of the ferment almost completely; thus, in one experiment with the above amount of saliva in the presence of 0·005 per cent sodium carbonate but 4·03 per cent of the starch was converted into sugar in 30 minutes at 40° C., while the same amount of saliva alone converted 27·08 per cent of the starch into sugar. By increasing the percentage of alkaline carbonate the diastatic action was stopped completely.

It it thus evident that the percentage of alkaline carbonate which absolutely or to a certain extent hinders the diastatic action of saliva can be designated only for a definite mixture, and not in a general sense. Langley and Eve* state that sodium carbonate of 0·0015 per cent causes a retardation in the action of ptyalin; our experiments with unneutralised saliva diluted, plainly show that even much smaller percentages of alkalinity may decidedly retard the action of the ferment, while in similarly diluted saliva 0·005 per cent of sodium carbonate may prevent diastatic action almost entirely.

Again Langley and Eve† state that the "amylolytic action of saliva becomes less the more alkaline salt there is in the solution; the rate of decrease is, however, slow compared with that which occurs when hydrochloric ocid is added in similarly increasing quantities." The rate of decrease, however, as our experiments plainly show, is dependent greatly upon the amount of dilution.

Destruction of Salivary Ptyalin by Sodium Carbonate.

To how great an extent is the retarding influence of sodium carbonate due to destruction of the ferment?

Langley and Eves‡ state that "sodium carbonate has a very slight destructive action on ptyalin, its retarding power is out of all proportion to its power of destruction."

The following experiments demonstrate the exact action of the sodium carbonate.

SERIES X.

70 c.c. of filtered saliva (the same saliva as used in Series IX.), were exactly neutralised with 0·2 per cent HCl and diluted to 140 c.c.

The following mixtures were then prepared:—

	1. C.c.	2. C.c.	3. C.c.	4. C.c.	5. C.c.
Diluted saliva	20	20	20	20	20
Na_2CO_3 sol...	0	20 0·1%	10 0·6%	20 0·6%	20 1%
H_2O	20	0	10	0	0
P.c. Na_2CO_3	0	0·05	0·15	0·30	0·50

These were warmed at 40° C. for 30 minutes, then neutralised with the amounts of dilute acid given below, water and starch added, and the mixtures again warmed at 40° C. for 30 minutes.

	1. C.c.	2. C.c.	3. C.c.	4. C.c.	5. C.c.
HCl 0·2 per cent..	0	6·88	20·6	41·3	68·8
Starch + H_2O ..	60	53·20	39·4	18·7	20·0
	100	100	100	100	128·8

	Wt. Cu in one-eighth.	Total amount sugar.	Starch converted.
1.	0·0998 grm.	0·4064 grm.	36·59 per cent.
2.	0·0991	0·4032	36·30
3.	0·0992	0·4040	36·40
4.	0·0474	0·1968	17·71
5.	0·0278	0·1192	10·73

In the above digestive mixtures the ultimate dilution of the saliva is the same as in Series IX., 1 : 10, and being the same saliva, the above results are directly comparable with those of Series IX. Warming saliva of the above strength with 0·05 and 0·15 per cent sodium carbonate for 30 minutes causes no destruction of the ptyalin whatever, as the results of experiments 2 and 3 indicate,

* The standard solutions of sodium carbonate were made from the chemically pure anhydrous salt.

* *Journal of Physiology*, vol. iv., No. 1.
† *Ibid.*
‡ *Ibid.*

consequently any diminished diastatic action in the presence of the above percentages of alkaline carbonate must be due to a simple retardation of the action of the ferment and not to its destruction. On the other hand, 0·3 and 0·5 per cent sodium carbonate under like conditions and with the same strength of saliva cause a marked destruction of the ferment, as the results of experiments 4 and 5 plainly show.

We have repeated the above series of experiments with a saliva, neutralised and diluted five times, using in each experiment 10 c.c. of the diluted fluid, equal to 2 c.c. of the original saliva. The only other deviation from the conditions already given consisted in warming the saliva with the alkaline carbonate for 1 hour instead of 30 minutes. We will not give the details of the experiment, as the results were mostly negative. With this amount of saliva, 0·15 per cent sodium carbonate almost completely destroyed the ferment in 1 hour's warming at 40° C., and even 0·05 per cent of the alkaline carbonate showed under these conditions a very great destructive action; thus, after heating the diluted saliva with 0 05 per cent sodium carbonate for 1 hour at 40° C., and then neutralising the mixture, it was able in 30 minutes to convert but 5·69 per cent of starch into sugar, while the same quantity of saliva simply warmed with water converted under like conditions 27·08 per cent of starch into sugar.* Under these circumstances, then, the destructive action of dilute sodium carbonate is very great. To what is due this great difference in the action of sodium carbonate of the same strength? Probably to the presence of the larger amount of albuminous matter which in the less diluted saliva possibly combines with the alkaline carbonate. It would follow, moreover, from our results, that any proteid compound formed has in itself no destructive action on the ferment, even to a slight extent. 0·005 per cent sodium carbonate causes no destruction in the ferment in 1 hour's warming at 40° C.; that is, in saliva of this dilution.

(To be continued.)

GERMANIUM, A NEW METAL.

In the *Derichte der Deutschen Chemischen Gesellschaft* (xix., Part 3) there is an account of a new metallic element discovered by Clemens Winkler. It occurs in argyrodite, a silver-ore from the Himmelsfürst mine, near Freyberg. Germanium, symbol Ge, has a great resemblance to antimony, though it is distinguished by certain well-marked reactions. If the sulphide is heated in the absence of air, *e. g.*, in a current of hydrogen, it forms a blackish crystalline sublimate, which at a higher temperature melts to brownish-red drops. This sulphide dissolves in ammoninm hydrosulphide, and is re-precipitated with a white colour by hydrochloric acid, and is again redissolved by ammonia. If arsenic or antimony is present the colour is yellow. If heated in air, or treated with hot nitric acid, the white germanium oxide is formed, which is not volatile at a red heat. The oxide dissolves in potassium hydroxide. If this solution is slightly acidified it gives a white precipitate on treatment with hydrogen sulphide. The oxide is easily reduced by hydrogen; the sulphide less easily. The metal is grey, volatile at a full red heat, though less readily than antimony. The vapour deposits small crystals resembling those of iodine, which do not melt. In a current of chlorine the metal yields a white chloride which is more volatile than antimony chloride. The acid solution gives a white precipitate with hydrogen sulphide. Herr Winkler is determining its atomic weight with a view to determine its place in the periodic arrangement.

* The amount of destruction produced in saliva of this solution by the above percentage of sodium carbonate does not appear to be constant, since we have found in several cases a much greater diastatic action after an hour's warming at 40° C. than in the above instance, due probably to the larger amount of ptyalin or proteid matter present.

ANALYSES OF COMMERCIAL FERTILISERS.*

(Continued from p. 113.)

On Phosphoric Acid (continued).

(2.) In the Table below are given the average results of the fifteen analyses of "South Carolina" and "Navassa," with the highest and lowest figures reported.

	South Carolina.			Navassa.		
	Average.	Highest.	Lowest.	Average.	Highest.	Lowest.
Soluble P_2O_5—	12·01	12·74	11·59	7·26	8·08	6·40
Reverted P_2O_5—	2·25	2·88	1·75	3·83	5·10	2·92
Available P_2O_5—	14·26	14·78	13·73	11·09	11·82	10·58
Insoluble P_2O_5—	1·28	1·56	0·78	5·93	6·37	5·17
Total P_2O_5—	15·54	16·12	15·09	17·02	17·72	16·31

The most important determinations are those of the available and the total phosphoric acid.

In "South Carolina" we notice a difference of about 1 per cent between the highest and lowest determination of available P_2O_5, or a difference in extreme cases of ½ per cent, from the mean of all results. In "Navassa" the difference between the highest and lowest results on available P_2O_5 is 1½ per cent, or a difference running from 0·7 per cent above the mean to 0·5 below the mean. The differences between the results of the determinations of total P_2O_5 are the same in "South Carolina" and a little larger in "Navassa" than the corresponding differences observed in the results on available P_2O_5.

The question now arises, Is the average results obtained by these fifteen chemists correct? The writer has endeavoured to answer the question, with strong probability, by the following experiments in the case of the total P_2O_5.

The purity of the reagents used and accuracy of manipulation were tested as follows:—

P_2O_5 was determined by ignition as pyrophosphate in a sample of finely pulverised "C. P." hydrogen sodium phosphate, which had been re-crystallised and dried.

The per cent of P_2O_5 was found to be 26·39, 26·43, 26·46, 26·46. Average, 26·43.

P_2O_5 was next determined in the same salt by precipitation with magnesia mixture. The results were 26·43, 26·35, 26·39, 26·42, 26·31. Average, 26·38, or 99 8 per cent.

In the same salt P_2O_5 was also determined by the molybdate method. The results were 26·41, 26·41, 26·31, 26·29, 26·42. Average, 26·37, or 99·8 per cent.

Reagents and manipulation being satisfactory, determinations of total P_2O_5 were made in "South Carolina" and "Navassa" by the molybdate method. The solutions of the phosphates were prepared as follows:—

(A.) Fused from 0·5 to 1 grm. phosphate with 7 grms. sodium carbonate, dissolved the mass in water and HCl, separated SiO_2, and filtered.

(B.) Digested the phosphate (0·6 to 0·5 grm.) with 20 c.c. concentrated HCl, diluted, and filtered.

(C.) Added to the phosphate (0·6 to 0·5 grm.) about 7 c.c. saturated solution of $Mg(NO_3)_2$, evaporated to dryness, and ignited. Dissolved in 20 c.c. concentrated HCl, diluted, and filtered.

(D.) Digested 0·5 grm. with about 2 c.c. oil of vitriol at 100° C. for three to five hours, diluted, boiled residue with strong HCl, and filtered.

A was tried on account of the suggestion of Dr. Shepard that in some cases pyrophosphate may be formed in a

* From the *Proceedings* of the Second Annual Meeting of the Association of Official Agricultural Chemists, at Washington, D.C., September 1, 1885. Edited by Charles W. Dabney, Jun., Ph.D., North Carolina Agricultural Experiment Station, Secretary.

phosphate heap, which would not be recovered in the usual method of solution.

D was tried to expel fluorine, which occurs in some phosphates, and is said to impair the accuracy of the molybdate method.

The results are given in the following Table, followed by others contributed by Mr. Clifford Richardson, of the Department of Agriculture :—

	S. Carolina.	Navassa.
A	15·35 15·45	16·96 16·85
B	15·51 15·31	16·80 16·83
C	15·43 15·37	17·00 16·93
D	15·22 15·50	17·00 17·20 16·98
Average	15·39	16·95
Ignited with $Mg(NO_3)_2$; solution in HNO_3	15·48	17·27
Ignited with $Mg(NO_3)_2$; solution in HCl	15·56	17·18
Ignited alone; solution in HCl	(15·59)	(16·87)
Not ignited; solution in HCl	15·26	17·26
Not ignited; solution in HNO_3	15·69	17·31
Average	15·49	17·25
Average of 15 analyses by official and commercial chemists	15·54	17·02

The writer considers the experiments here given as confirming the results obtained by other chemists, simply because they were made under varying conditions, while the others were made presumably under the same conditions.

The results obtained this year leave much to be desired. The samples, it is believed, were as nearly identical as it is possible to make them, and a nearer agreement between chemists on identical samples is necessary and attainable.

The Sub-committee of the Chemical Trades Section of the London Chamber of Commerce (Chemical News, 1884, p. 230) decided that for their uses a difference of less than 1¼ per cent of tricalcium phosphate (equivalent to about 0·7 per cent P_2O_5) was admissible.

If differences of 1¼ per cent or more occurred the analysts concerned were to be requested to explain the discrepancy.

No determinations of available or total P_2O_5 in South Carolina and three in Navassa differ 0·7 per cent from the mean of all results, but as between the highest and lowest figures there are many differences of more than 0·7 per cent. Certainly a chemist who cares for his own reputation and for justice will not let a difference of 0·7 per cent between his own and his neighbour's determination pass without assuring himself by a repetition of his own work and by examination of his reagents that his own result is very nearly correct for the sample on which he worked.

In conclusion your Committee recommends that the methods of analysis adopted at our last meeting be amended as follows :—

Before the "determination of phosphoric acid in fertilisers" insert the following :—

Determination of Moisture in Fertilisers.

(*a.*) In potash salts, nitrate of soda, and sulphate of ammonia, heat 1 to 5 grms. at 130° C. till the weight is constant, and reckon water from the loss.

(*b.*) In all other fertilisers heat 2 grms., or, if the sample is too coarse to secure uniform lots of 2 grms. each, 5 grms. for five hours at 100° in an air-bath.

Your Committee also recommends the following description of the Association's method of determining "citrate insoluble phosphoric acid" :—

The method of extracting "reverted" phosphoric acid was originally designed for and is applicable only to superphosphates, plain or nitrogenised, and was not intended to be applied to rock phosphates, natural guanos, or any other non-acidulated materials to test their relative solubility or availability. In case, however, a determination of citrate insoluble phosphoric acid is required in these non-acidulated goods, it is to be made by treating 2 grms. of the phosphatic material, without previous washing with water, precisely in the way above described, except that in case the substance contains much animal matter (bone, fish, &c.) the residue insoluble in ammonium citrate is to be ignited with magnesium nitrate.

Your Committee further recommends that in all other respects the method adopted at our last meeting for the determination of P_2O_5 in its three states be rigorously followed during the coming year.

They specially urge attention to the following points :—

(1.) The solution of ammonium citrate to be strictly neutral and of the specific gravity indicated.

(2.) Perfect solution of the phosphate in acid. After boiling with acid, diluting, and decanting, it is well to boil the insoluble residue again with strong acid.

(3.) The magnesia mixture to be added not more rapidly than indicated (one drop per second). (Peitsch, Rohn, and Wagner, *Fres. Zeitschr. fur Analyt. Chem.*, xix., 448.)

Since the ignition with $Mg(NO_3)_2$ requires some time and an additional transfer of the material from one vessel to another, which always involves the possibility of mechanical loss, experiments are desirable to determine whether organic matter can be destroyed or made harmless by oxidation in the wet way, by fuming nitric acid or other reagents in the flask in which the subsequent solution of the phosphate is to be made.

It is also desirable to know to what extent silica passes into solution when phosphates of various kinds are digested in strong acid. A single experiment on "South Carolina" gave the writer—

	Per cent.
Total sand and silica	3·92
Brought into solution by boiling in strong HCl	0·02
Brought into solution by ignition with $Mg(No_3)_2$ and solution in strong HCl	0·05

It is also desirable to know what effect silica in solution has on the determination of P_2O_5 by the molybdate method. The testimony on this point is conflicting. (See Bertrand, *Jahresber. Ag. Chem.*, xxvi., 318; Lindo, Chemical News, xxxviii., 1884, 247 *et seq.*; *Bied. Centr. Ag. Chem.*, 1884, 642; Atkinson, *Fres. Zeitschr. f. Anal. Chem.*, xviii., 477; Jenkins, *Journ. f. Prakt. Chem.*, xiii., 237.)

Your Committee also express the belief that an annual distribution of samples and comparison of results will be of great use in securing accuracy and uniformity among analysts, and urge on the members of the Association the desirability of promptly analysing and reporting results on samples which they receive.

All of which is respectfully submited.

E. H. Jenkins, *Chairman.*
H. C. White.
W. C. Stubbs.

Mr. Gladding said a study of the results of the analyses just given, especially those of Dr. Jenkins and Mr. Richardson, shows that while working on acid phosphates made from Charleston and Navassa rock the results were practically identical whether a simple solution in HCl or HNO_3, a fusion with Na_2CO_3, or an ignition with H_2SO_4 were employed. He therefore argued that, as the simplest manipulation was always to be preferred, other things

being equal, the use of magnesium nitrate be omitted in all such cases where it is, without dispute, unnecessary.

Dr. Dabney found the manipulation of the phosphate in a capsule with magnesium nitrate, as laid down in the adopted method, awkward and perilous. Fine cracks form in the capsules which are scarcely to be seen, but which let a little of the concentrated solution leak through at the next step. Like Mr. Gladding, and for these additional reasons, he had not treated simple rock phosphate with magnesium nitrate and ignited, except in making experiments and when the character of the phosphate was uncertain. He hoped the Association would recognise this as sufficient.

Dr. Jenkins said the reason why HCl was adopted by the Association as a solvent for phosphates, instead of HNO_3 was that it more readily and quickly brings them into solution. With care HNO_3 will answer perfectly. During an entire season a comparison was made of the two solvents in his laboratory by different chemists. In the rather small number of cases where there was disagreement the HCl solution invariably gave slightly higher results. It may be claimed that this was due to silica brought into solution by the HCl. Two trials made with reference to this point showed that it dissolved silica very little, if at all. (0·02 and 0·05 per cent silica were dissolved from South Carolina phosphate, which contained 3·92 per cent of sand and silica.) The presence of chlorides, introduced by hydrochloric acid, somewhat retards but does not prevent the precipitation of P_2O_5.

He believes the reduction of P_2O_5 to pyrophosphate during ignition of the insoluble residue from the citrate extraction is slight. He had at hand only the results of a single trial. Three such residues from a superphosphate containing animal matter were ignited directly, three others were fused with sodium carbonate, silica was separated, and P_2O_5 was determined in the six lots. The results were :—

	Average.
Ignited : 2·82, 2·75, 2·91	2·83
Fused : 2·85, 2·96, 3·04	2·95

(To be continued).

THIRD REPORT OF THE COMMITTEE*

RE-APPOINTED FOR THE PURPOSE OF DRAWING UP A STATEMENT OF THE

VARIETIES OF CHEMICAL NAMES WHICH HAVE COME INTO USE,

FOR INDICATING THE CAUSES WHICH HAVE LED TO THEIR ADOPTION, AND FOR CONSIDERING WHAT CAN BE DONE TO BRING ABOUT SOME CONVERGENCE OF THE VIEWS ON CHEMICAL NOMENCLATURE OBTAINING AMONG ENGLISH AND FOREIGN CHEMISTS.†

PROCEEDINGS OF SOCIETIES.

CHEMICAL SOCIETY.

Thursday, March 4th, 1886.

Dr. HUGO MÜLLER, F.R.S., President, in the Chair.

CERTIFICATES were read for the first time in favour of Messrs. Carl Bennert, Ph.D., Blaydon, near Newcastle; Edwin Ebenezer Burnett, 118, Huddleston Road; Arthur Robert Ling, 14, Woburn Place, Russell Square, W.C.; Frank Morel, Aldergate Chemical Works, Southall; Dr. Robson Roose, 45, Hill Street, Berkeley Square, W.

The following were elected Fellows of the Society:—Messrs. James Henry Allan, Henry K. G. Bamber, Leopold Mandeville Deane, Preo Loll Dey, Adolph Dresel, Herbert Samuel Elworthy, John William Ellis, Caleb Ferrey, M.B., B.Sc., James Arthur Formoy, Francis W. L. Glenfield, Bertram Harvey Hart, Andrew Henderson, George Thomas Holloway, Arthur Percy Hoskins, William Lang, jun., Arthur Pillans Laurie, Peter MacEwan, Walter Newton, Eugene Obach, Oliver Quibell, James Galbraith Ross, Richard Spencer, Arthur John Starey, Francis Napier Sutton, Charles Metford Thompson, Julius Wertheimer, Sidney Williamson, Edward Willmore, William T. Wright, and Brougham Young.

19. "*A New Element: Germanium.*" By CLEMENS WINKLER.

The author, in a letter addressed to the Society, dated Freiburg, Saxony, February 21st, 1886, states that he has discovered in the mineral *Argyrodite* a new non-metallic element, closely related to arsenic and antimony, and that he has named it *Germanium*.

Argyrodite is a new mineral discovered at Freiburg by by A. Weisbach, consisting of silver, sulphur, and germanium.

20. "*The Influence of Temperature on the Heat of Chemical Combination.*" By S. U. PICKERING.

A large number of experiments have been made by the author, with the view of ascertaining whether the heat of combination is independent of temperature, or whether, if not, the variations are of a regular nature. According to Kopp's determinations of specific heats, the heat of combination of solids should be uninfluenced by temperature, but the methods available for ascertaining specific heats would be too imperfect to show any alterations in the heat of combination unless these were very great. The particular cases selected were the heat of hydration of a salt and the heat of formation of double salts. The sulphates were the salts chosen.

Every means was adopted for rendering the experiments as precise as possible; the temperatures employed were confined within the ordinary range of atmospheric temperatures; as many as seven different thermometers were used, the more delicate of which read to less than 1/3000° C., and a method was devised whereby the same portion of any instrument was used for every experiment with any particular substance, whatever the temperature might be. The proportion of salt to water taken was 1:400 formula weights with the single sulphates, and 1:800 with the double sulphates.

Hydrates in Solution.—The results when plotted as curves exhibit very remarkable features. In no case is the heat of dissolution of any of the salts represented by a straight line, nor even by a single curve, but consists of a series of curves more or less regular in their nature.

Hydrated potassium magnesium sulphate exhibits the greatest number of such changes; a straight line may be drawn so as to touch, or nearly touch, the portions of the curves at 2·5°, 7·5°, 15°, and 22·5° C., the portions intermediate between these points corresponding about 100 calories above this straight line. Hydrated magnesium sulphate exhibits similar peculiarities, but fewer in number, the points of minimum heat evolution being about 3°, 14°, and 22° C. With hydrated copper sulphate the heat of dissolution appears to be represented by a series of straight lines rather than curves. Hydrated potassium copper sulphate presents the appearance of one curve, broken only by a deep indentation extending from 12·5° to 15°. With hydrated sodium sulphate there is a depression between 5·5° and 10·5°, the heat of dissolution above this point being probably represented by a straight or nearly straight line.

The curves of the anhydrous salts generally exhibit peculiarities resembling those of the corresponding hydrated salts, but not always. With potassium sulphate there is a break at 14°; a similar one occurs with lithium sulphate, but in the case of sodium sulphate such a break is absent. The curves of these three salts do not show any marked resemblance.

The increase in the heat of dissolution of a salt which thus takes place at certain temperatures can only be attributed, in the author's opinion, to the formation of some new and higher hydrate. That an increase of temperature should favour the formation of such is not considered extraordinary, when it is remembered that the temperatures at which the observations were made are comparatively low, and that with sodium sulphate, where we have other reasons for considering a high temperature would

favour the dissociation of the salt from its water, no such increase takes place after 10·5°, a much lower temperature than in any other case. No special changes were noticed at 4° C., the temperature of the maximum density of water. The author considers that the heat of formation of these higher hydrates is probably not an inconsiderable quantity in comparison to that of the known hydrates of the salt, but it is impossible to determine its exact value in any special case.

The occurrence of these successive changes in the constitution of a salt in solution will involve successive variations in the specific heat of their solution; the temperature of the latter, therefore, will rise under the influence of a constant source of heat, not in a regular but in an undulatory manner.

Water of Crystallisation.—A comparison of the heat of dissolution of the same salt in the hydrated and anhydrous condition gives the heat of formation of the solid hydrated salt. When the various values obtained for this at different temperatures are represented diagrammatically they form a series of curves showing that the heat of this combination is not a constant quantity. With magnesium sulphate the heat of hydration increases from 13,100 cals. at 3° to 13,300 cals. at 23°, there being a small but questionable break at 14° C. With copper sulphate the variation is much more marked; the line forms one curve from 2° to 9°, another from 9° to 17°, after which it again rises, attaining the value of 11,320 cals. at 23°, whereas at 2° it was only 10,780 cals. The heat of hydration of the double salts shows similar irregularities, as well as a similar tendency to increase with the temperature. With sodium sulphate only is a decrease in value observed as the temperature rises, this decrease beginning at about 15°, after experiencing some remarkable fluctuations at lower temperatures.

These fluctuations in the heat of hydration of a salt the author attributes to intramolecular re-arrangements; changes of a nature similar to those which cause the same substance, sometimes even when an element, to exhibit different physical and chemical properties. The general tendency towards an increase in the heat of combination as the temperature rises is in accordance with what has already been observed in other cases.

From these variations in the heat of hydration it follows that the specific heat of a solid hydrated salt will be subject to small variations, as in the case of its solution, and also that it will not be exactly equal to the sum of the specific heats of the anhydrous salt and water, but generally slightly less.

It is observed that the temperature at which the heat of hydration of a solid salt is a minimum corresponds to an increased heat in the dissolution of the hydrated salt, as if the possibility of a higher hydrate being formed were due to there being less energy expended in retaining the water already combined.

Double Salts.—The heat of formation of the double salts, $MgSO_4,K_2SO_4$ and $CuSO_4,K_2SO_4$, in the solid and anhydrous condition, was calculated from the data already alluded to. This quantity appears to vary also with the temperature; with both salts it attains a minimum at about 14°, the extreme variation with the copper compound being as much as 640 cals., from −240 cals. to +400 cals. One of the most remarkable features in the variation of this quantity is that an increase in it occurs at those temperatures which are marked by a *decrease* in the heat of combination of the same double salt with its water of crystallisation, thus bearing out the conclusions previously drawn from a comparison of this latter quantity with the heat of dissolution, as to there being some principle of intramolecular compensation, whereby an increase in the energy of combination between any two portions of a molecule can take place only at the expense of the energy between these and the other portions.

21. "*The Salts of Tetrethylphosphonium and their Decomposition by Heat.*" By Professor E. A. Letts and Norman Collie, Ph.D.

The authors confirm Hofmann's statement that *tetrethylphosphonium hydroxide* is resolved on heating into ethane and triethylphosphine oxide; the change occurs quantitatively. The *chloride*, PEt_4Cl, is resolved quantitatively into triethylphosphine hydrochloride and ethylene. On heating the *carbonate* they obtained triethylphosphine together with its oxide, and diethylketone, carbon dioxide, and tetrane, whereas Hofmann and Cahours state that it yields triethylphosphine and ethyl carbonate. The *acid carbonate* behaves similarly. The *acetate* appears to undergo two distinct changes, and to be resolved partly into triethylphosphine oxide and methylethylketone, and partly into triethylphosphine, carbon dioxide, ethylene, and methane. The *benzoate* is decomposed in a similar manner, ethylphenylketone and benzene taking the place of ethylmethylketone and methane. The products of decomposition of the *oxalate* at 200° to 300° are triethylphosphine and its oxide, ethylene, carbon monoxide and dioxide, and perhaps diethylketone. If the oxalate be heated to 160° with the minutest trace of sulphur, a deep indigo-blue colour becoming green and finally yellow is produced: this reaction furnishes an excellent test for sulphur. The *sulphate* yields almost quantitative amounts of triethylphosphine sulphide and oxide, together with charred products. A concentrated solution of the *cyanide* decomposes when heated, and yields triethylphosphine oxide, ethane, and hydrogen cyanide; a small quantity of what appears to have been propionitrile was also obtained. The *iodide* decomposes in a complex manner, and yields charred products.

22. "*The Formation of Acids from Aldehydes by the Action of Anhydrides and Salts, and the Formation of Ketones from the Compounds resulting from the union of Anhydrides and Salts.*" By W. H. Perkin, Ph.D., F.R.S.

The method of preparing unsaturated acids from aldehydes discovered by the author has of late been the subject of much discussion, Fittig especially contending that condensation takes place between the aldehyde and the *salt*, and not, as the author supposes, between the aldehyde and the *anhydride*. Believing the arguments put forward by those who oppose this latter interpretation to be inconclusive, he has resumed the study of the subject; the experiments are as yet incomplete, however, and only one observation bearing on the question is fully discussed in the paper. The author has previously shown that when a mixture of isobutyric anhydride, sodium isobutyrate, and benzaldehyde is heated, carbon dioxide and butenylbenzene are produced; these result from the decomposition of phenylhydroxyisobutyric acid, which Fittig has proved to be the first product of the reaction. He now finds that on heating a mixture of benzaldehyde, isobutyric anhydride, and an acetate, about 60 per cent of the theoretical amounts of butenylbenzene and carbon dioxide are obtained; whereas, on employing acetic anhydride and sodium isobutyrate cinnamic acid was obtained in considerable quantity, and less than half as much carbon dioxide and butenylbenzene as in the previous experiments. These results afford strong evidence that condensation takes place between the aldehyde and the anhydride, and not between the aldehyde and the salt.

The paper mainly consists of an account of the results obtained on heating anhydrides with their salts. On boiling a mixture of butyric anhydride and sodium butyrate, carbon dioxide is gradually evolved and dipropylketone is formed. Isobutyric anhydride and sodium isobutyrate react in a similar manner. A mixture of sodium propionate with excess of propionic anhydride, heated in sealed tubes at 180—190°, yields carbon dioxide and diethylketone; and acetone is obtained in like manner from acetic anhydride and an acetate. The author believes that the formation of the ketone depends on the interaction of the salt and the anhydride, and that this is the case appears to be proved by the observation that methylpropylketone is obtained if a mixture of sodium acetate and butyric anhydride be heated.

23. "*A New Method of Preparing Tin Tetrethide.*" By Professor E. A. Letts and Norman Collie, Ph.D.

In preparing zinc ethide by Gladstone and Tribe's method, the authors obtained a liquid by-product which they ultimately ascertained was tin tetrethide. Experiments were therefore made with zinc-tin alloys containing from 1 to 50 per cent of tin; the yield of tin tetrethide, calculated as percentage of tin converted, varied from 27–56 per cent, but in most of the experiments about 50 per cent of the tin present was converted, whatever the composition of the alloy. The yield of tetrethide was almost proportional to the mass of tin in the alloy until it contained one-third tin; it then became almost inactive, and the time necessary to complete the reaction increased enormously. On adding powdered tin to the zinc-copper couple together with ethyl iodide, tin tetrethide was produced on heating; and a similar result was obtained when zinc ethiodide was heated with powdered tin, but it was necessary to raise the temperature to 160°. Alloys of zinc with 20 per cent antimony, aluminium, bismuth, and lead, when heated with ethyl iodide, gave only zinc ethide.

24. "*Contributions to the History of Cyanuric Chloride.*" By Alfred Senier, M.D.

On heating together cyanuric chloride, $C_3N_3Cl_3$, and sodium acetate in closed tubes at 100°, sodium cyanurate, $C_3N_3O_3Na_3$, and acetyl chloride are produced, but interaction takes place only partially. Silver acetate is not attacked by the chloride; and cyanuric acid and acetic anhydride do not act on each other. On heating sodium formate with cyanuric chloride, sodium cyanurate, carbonic oxide, and hydrogen chloride are formed. Sodium benzoate and cyanuric chloride give benzoyl chloride and sodium cyanurate, 88 per cent of the theoretical yield of the former being obtained. The action of cyanuric chloride on benzamide is similar to that of phosphorus pentachloride, and results in the formation of cyanuric acid, benzonitrile, and hydrogen chloride. *Benzoyl cyanurate*, $C_3N_3(C_7H_6O_2)_3$, is readily obtained on heating a mixture of benzoyl chloride and silver cyanurate at 100°; it is readily hydrolysed, if heated for a short time with water at 100°, into benzoic and cyanuric acids.

25. "*The Action of Naphthylamine on Cyanuric Chloride.*" By Harold H. Fries.

The author has succeeded in displacing the three chlorine-atoms in cyanuric chloride one by one by the group $NH{\cdot}C_{10}H_7$. The dichloride, $C_3N_3Cl_2(NH{\cdot}C_{10}H_7)$, and the monochloride, $C_3N_3Cl(NH{\cdot}C_{10}H_7)_2$, are obtained on mixing the proper quantities of cyanuric chloride and naphthylamine, both dissolved in ether; they crystallise from hot alcohol in needles, the former melting at 149°, the latter at 215°. When either of these bodies is heated with the proper quantity of amine at 100°, *naphthylmelamine*, $C_3N_3(NH{\cdot}C_{10}H_7)_3$, is formed; it melts at 223°.

26. "*Sulphine Salts containing the Ethylene Radical.*" Part I. *Diethylene-sulphide-methyl-sulphine Salts.*" By Orme Masson, M.A., D.Sc.

Two substances of the empiric formula C_2H_4S have been described, one being an amorphous insoluble non-volatile compound, concerning whose constitution nothing is known; the other is crystalline, dissolves in alcohol, ether, and carbon disulphide, boils at 200°, and, as Husemann has shown, has a vapour-density corresponding to the formula $(C_2H_4)_2S_2$. The author describes the preparation of this latter; he then discusses its constitution, showing that it is adequately represented by the formula $S\begin{Bmatrix}C_2H_4\\C_2H_4\end{Bmatrix}S$.

This sulphide unites directly with methyl iodide to form *diethylene-sulphide-methyl-sulphine iodide*—

$$S\begin{Bmatrix}C_2H_4\\C_2H_4\end{Bmatrix}S\begin{Bmatrix}CH_3\\I\end{Bmatrix}$$

A series of derivatives prepared from this iodide are described, viz.:—The iodide, $C_5H_{11}S_2I$; the tri-iodide, $C_5H_{11}S_2I_3$; the nitrate, $C_5H_{11}S_2NO_3$; the silver salt, $C_5H_{11}S_2NO_3{\cdot}AgNO_3$; the sulphate, $2(C_5H_{11}S_2)_2SO_4{\cdot}7H_2O$; the chloride, $C_5H_{11}S_2Cl$; the chloroplatinates—

$$(C_5H_{11}S_2Cl)_2PtCl_4, (C_5H_{11}S_2Cl)_4{}_3PtCl_4, (C_5H_{11}S_2Cl)PtCl_4, C_{10}H_{21}S_4Pt_2Cl_9);$$

the gold salt, $C_5H_{11}S_2Cl{\cdot}AuCl_3$; the mercury salt—

$$C_5H_{11}S_2Cl{\cdot}HgCl_2;$$

the hydroxide, $C_5H_{11}S_2OH$; a volatile oil, $C_{12}H_{24}S_5$.

In their general characters the salts of the base resemble those of trimethyl-sulphine, but they differ in some important particulars, of which the following are the most striking:—

1. There is much less tendency to form addition products with the halogens.
2. The salts are decomposed by potash.
3. The hydroxide undergoes a peculiar decomposition, slowly when cold, rapidly on heating; the chief product of which is the oil $C_{12}H_{24}S_5$.
4. The compounds formed by the chloride with platinic chloride are peculiarly various, and are possessed of characteristic properties.
5. None of the salts examined, with the exception of the sulphate, is at all deliquescent.

The constitution proposed by the author for this sulphine base represents it as trimethyl-sulphine in which two methyl-groups are displaced by the dyad (comparatively negative) group $S(C_2H_4)_2$. This view of their constitution affords an explanation of the first two of the above-mentioned characteristics of the base.

27. "*Sulphine Salts containing the Ethylene Radical.* Part II. *On Dehn's Reaction between Ethylene Bromide and Alkyl Sulphide.*" By Orme Masson, M.A., D.Sc.

In 1865 Dehn published an account of the action of ethylene bromide on ethyl sulphide (*Annalen*, Suppl. IV., 83), which he summed up in the following scheme:—

(1.) $2C_2H_4Br_2 + 2(C_2H_5)_2S = (C_2H_4)_2S_2 + 4C_2H_5Br.$
(2.) $C_2H_5Br + (C_2H_5)_2S = (C_2H_5)_3S.$
(3.) $C_2H_4Br_2 + (C_2H_5)_2S = (C_2H_5)_2(C_2H_4)S^{VI}Br_2.$
(4.) $C_2H_4Br_2 + C_2H_4S = (C_2H_4)_2S_2{}^{VI}Br_2.$

The truth of equations (1) and (2) was well proved; that of (3) and (4) rested on rather doubtful evidence.

If the compounds $(C_2H_5)_2(C_2H_4)S^{VI}Br_2$ and—

$$(C_2H_4)_2S^{VI}Br_2$$

really exist, they are unique specimens of a class of sulphinic salts, and are of considerable theoretic interest. An investigation, however, of the circumstances attending the formation of the salts to which Dehn attributed these formulæ, of the properties of their platinum salts (as described by Dehn), and of the analyses on which this theory was based, conclusively shows that Dehn was really dealing with salts analogous to those described by the author in Part I. of this communication. The author supports this conclusion by proving that sulphine salts possessed of the required properties are actually formed when diethylene disulphide is heated with ethyl bromide and with ethylene bromide. He therefore substitutes the following equations for Dehn's third and fourth:—

(3.) $C_2H_5Br + (C_2H_4)_2S_2 = (C_2H_4)_2S_2(C_2H_5)Br.$
(4.) $C_2H_4Br_2 + (C_2H_4)_2S_2 = \{(C_2H_4)_2S_2\}_2(C_2H_4)Br_2.$

28. "*The Identity of Certain Mixed Ethereal Oxalates.*" By L. Gordon Paul.

The author has compared the methylic ethylic oxide obtained, 1, by adding the theoretical amount of $CH_3{\cdot}OH$ to the chloride $COCl{\cdot}COOEt$, and 2, by adding the theoretical amount of $C_2H_5{\cdot}OH$ to the chloride $COCl{\cdot}COOMe$, and concludes that the two reactions furnish the same product. If an excess of alcohol be used, methylic oxalate in the one case, and ethylic oxalate in the other, is obtained in place of the mixed salt; but whereas the displacement of ethyl by methyl takes place at once and is very complete, that of ethyl by methyl is much more gradual and less complete. Methylic oxalate may be converted into ethylic oxalate by heating it with methylic

alcohol, and *vice versâ*. Methylic ethylic oxalate is converted by repeated distillation into a mixture of methylic and ethylic oxalates.

ROYAL INSTITUTION OF GREAT BRITAIN.

General Monthly Meeting, Monday, March 1, 1886.

WARREN DE LA RUE, M.A., D.C.L., F.R.S., Manager and Vice-President, in the Chair.

THE following were elected Members of the Royal Institution:—

John Abercrombie, Sen., M.D., F.R.C.P., William Henry Barlow, Esq., F.R.S., M. Inst. C.E., Alfred Carpmael, Esq., Henry Doetsch, Esq., John Piggin Fearfield, Esq., R. Gent-Davis, Esq., M.P., John Hopkinson, Esq., M.A., F.R.S., John Inglis, Esq., Major E. Cecil Johnson, Mrs. T. C. Leitch, Mrs. S. Joshua, George Palmer, Esq., Sir Ughtred Kay-Shuttleworth, Bart, M.P., Silvanus P. Thompson, Esq., Sir William Thompson, D.C.L., LL.D., F.R.S., Walter Tomlinson, Esq., M.A.

Seven Candidates for Membership were proposed for election.

The Presents received since the last Meeting were laid on the table and the thanks of the Members returned for the same.

UNIVERSITY COLLEGE, LONDON.

CHEMICAL AND PHYSICAL SOCIETY.

Thursday, March 4th, 1885.

C. E. CASSAL, F.I.C., F.C.S., President, in the Chair.

"*On some Antiseptics for Food Preservation.*" By H. L. SULMAN and E. E. BERRY, F.C.S.

The authors described their experiments on the antiseptic properties of the various borates, salicylates, and benzoates; especially with regard to the preservation of milk, for which purpose the two former classes have been extensively recommended and used.

Of the borates the free acid itself possesses the greatest efficiency; and several of the widely-advertised antiseptic compounds—such as "*aseptin*," "*glacialine*," and "*boroglyceride*," which contain boracic acid in admixture with borax, alum, glycerin, &c.—were found to owe their power almost entirely to their ratio of contained free H_3BO_3.

A sample of the last-named compound, "*Barff's boroglyceride*," purporting to be the boracic ether of glycerin, $C_3H_5BO_3$, was analysed, and found to consist of about 25 per cent of the true ether, with 75 per cent of free boracic acid and glycerin in equivalent proportions. In experimenting with the true compound (the ice-like solid) the authors obtained results slightly differing from the published descriptions, inasmuch as the addition of water in *any* proportion was found to immediately resolve the glyceric borate into the free acid and glycerin. This decomposition therefore occurs on adding the compound to any aqueous liquid, or when it is brought into contact with any animal tissue; and, in view of the necessarily somewhat restricted quantity of antiseptic capable of being used, the liberated glycerin has practically no antiseptic action. Hence it follows that the value of "boroglyceride" is entirely dependent upon the 45 to 50 per cent of free H_3BO_3, which it liberates on use. And its advertised beneficial effects in antiseptic surgery and in food preservation will be equally well obtained by employing half the quantity of the far cheaper boracic acid.

In reviewing the available evidence with regard to the physiological effects produced by the constant administration of small doses of boracic acid and the borates in food, the authors decide strongly against their employment as agents for food preservation, especially when applied to milk, on account of the greater risk to children and infants.

The still more serious objections which can be urged on these grounds against the use of salicylic acid and the salicylates (which for food preserving have been penalised in France upon the advice of a late French Commission) are rendered unnecessary in the case of milk, by the fact that this generally potent class of antiseptics is utterly useless for the purpose.

Benzoic acid is useless, owing to its tendency to precipitate the casein; but the best results were obtained by the use of sodic benzoate, which is quite tasteless, is one-third more powerful than boracic acid, and is entirely unattended by any evil physiological effects when taken in small quantities for prolonged periods.

CHEMICAL NOTICES FROM FOREIGN SOURCES.

NOTE.—All degrees of temperature are Centigrade unless otherwise expressed.

Comptes Rendus Hebdomadaires des Séances, de l' Académie des Sciences. Vol. cii., No. 8, February 22, 1886.

On the Equivalent of the Terbias.—Lecoq de Boisbaudran.—Inserted in full.

Use of Potassium Sulphate in the Fractionations of the Rare Earths.—Lecoq de Boisbaudran.

Analysis of Air collected at Cape Horn.—A. Müntz and E. Aubin.—The mean percentage of oxygen found was 20·864.

Action of Gaseous Hydrochloric Acid upon Iron.—F. Isambert.—The proportion of hydrogen set free in the gaseous mixture is so much the smaller as the temperature is higher. Thus a gas which no longer acts upon iron at the temperature of dull redness contains from 89 to 91 per cent of hydrogen, at bright redness from 67 to 69, and at a still higher temperature only 55 per cent. The action of hydrochloric acid, therefore, follows the same course as that of watery vapour upon iron in the experiments of H. Deville. The pressure of the gaseous mixture does not seem to exert any influence.

New Researches on the Alkaline Earthy Manganites.—G. Rousseau.—As the temperature falls the manganous acid combined with lime tends to become polymerised.

Observations relative to M. Joly's Note on the Titration of Phosphoric Acids by means of various Indicators.—R. Engel.—M. Joly in his investigation on the titration of phosphoric acid with various indicators concludes that the blue C4B, the reactions of which the author has studied, does not admit of "precise application." If this *savant* has in view merely the determination of phosphoric acid he combats an opinion which M. Engel has never advanced. The latter has, in fact, pointed out that on titrating disodic phosphate with normal potassa the change of colour begins at the 50th degree, whilst 59 degrees are theoretically necessary. Under the most favourable circumstances there would be therefore an error of about 16 per cent. The figures which M. Joly finds show that disodic phosphate, alkaline to litmus, is acid to the soluble blue, but the number of c.c. of normal potassa necessary to arrive at the point where the change of colour begins is smaller in M. Joly's experiments than in those of M. Engel. The latter used a concentrated solution, whilst M. Joly diluted 1 eq. of phosphoric acid with 6 litres of water. But it is well known that the trisodium and tripotassium phosphates are readily decomposed by water. The author considers that we may safely doubt the existence of a reagent, which in all grades of dilution will indicate the neutralisation of feeble acids,

or that of bodies having similar chemical functions. Thus the blue C_4B, which permits of the determination of prussic acid in a 25 per cent solution, is quite unfit for the determination of the same acid in laurel water. The law of definite proportions and that of multiple proportions do not hold good in all cases when the question is the neutralisation of dissolved acids by bases. The author has recently shown that on adding to a mol. of oxalic acid a mol. of ammonia or potassa the solution obtained does not contain respectively the acid oxalate of these bases, but a mixture of the neutral and the acid oxalate and the quadroxalate. If a little more or a little less of these acids is added the three salts still exist.

The Formation of Monatomic Alcohols derived from the Oil of Turpentine.—MM. Bouchardat and Lafont.—The authors have already shown that setting out from French oil of turpentine several acetates may be obtained of the same formula, but of very different properties. From these acetates the authors have since obtained the corresponding monatomic alcohols.

The Action, in the Cold, of Alcoholic Chlorides upon Ammonia and upon the Methylic Amines.—MM. Vincent and Chappuis.—This paper does not admit of useful abstraction.

Behaviour of Alkaline Hydrosulphides with Compound Ethers.—Christian Göttig.—It appears that acetic ether, and probably other ethers of its class, are not directly decomposed by the alkaline hydrosulphides, but only after the decomposition of these sulpho-bases.

Reply to H. E. Beyer on the "Action of Acetone upon Aniline."—C. Engler and P. Riehm.

Remarks on the above Reply.—C. Beyer.—A discussion on the right of Engler and Riehm to publish researches on a subject the continuation of which C. Beyer had reserved for himself in an earlier publication.

Action of Phenylhydrazin upon the Organic Anhydrides.—B. Hotte.—On heating equal mols. phthalic anhydride and phenylhydrazin to 150°, water is split off, and the resinous dark-red product yields phthalyl-phenyl hydrazin.

Chinolin Derivatives from Isatic Acid.—W. Pfitzinger.—Acetone in alkaline solution is condensed with isatic acid (two mols. of water being eliminated) to an acid of the composition of a methyl-chinolin- carbonic acid.

MISCELLANEOUS.

Petroleum.—At the Society of Arts on Monday, March 8th, Mr. Boverton Redwood, F.I.C., F.C.S., delivered the first of a Course of four Cantor lectures on "Petroleum and its Products." The lecturer commenced by giving a historical account of petroleum, pointing out that the valuable properties of this substance were undoubtedly well known to Herodotus and other historians who wrote during the five centuries preceding the Christian era, and that the inflammable nature of petroleum-gas was probably turned to account by the Persian Fire Worshippers as much as 2500 years ago. Having traced the progress of the petroleum and shale oil industries from their commencement to the present time, the lecturer proceeded to deal with the geographical and geological distribution of petroleum, and showed that there was hardly a country in which it had not been found, though not always in the same geological formation. The lecturer then referred to a representative series of specimens of petroleum from various parts of the world, in illustration of his statements as to the very variable physical characters of the material, and concluded by explaining the chemical composition of petroleum, showing that the Russian oil differs in this respect from the American, though carbon and hydrogen are the principal constituents of both.

NOTES AND QUERIES.

*** Our Notes and Queries column was opened for the purpose of giving and obtaining information likely to be of use to our readers generally. We cannot undertake to let this column be the means of transmitting merely private information, or such trade notices as should legitimately come in the advertising columns.

Sawdust.—Can any of your readers inform me by what process I can get a hard substance, such as can be moulded, from sawdust? I believe this is done by chemically reducing the sawdust to a pulp and submitting it to pressure.—J. N. Palmer.

MEETINGS FOR THE WEEK.

Monday, 15th.—Medical, 8.30.

EXPIRATION OF PARTNERSHIP.

BROOKE, SIMPSON, & SPILLER,

LIMITED,

ANILINE DYE MANUFACTURERS,

LONDON AND MANCHESTER.

Incorporated under the Companies Acts, 1862 to 1883, whereby the liability of Shareholders is limited to the amount of their Shares.

£150,000 Share Capital, in 30,000 Shares of £5 each, viz.:—

24000 A SHARES, entitled to Seven per Cent Preference Dividend.
6000 B SHARES, entitled to a Dividend, after payment of Seven per Cent on the A Shares.
All the B Shares, and 2000 of the A Shares, will be taken by the Vendors as part of the purchase.

The residue of the profits each half-year, after payment of Seven per Cent on Shares A and B, will be applicable for division proportionately between the A and B Shareholders.

In case the net profits for any five consecutive years shall amount to Forty per Cent, or an average of Eight per Cent per annum, on the total paid up Capital on both A and B Shares, the B Shares will be converted into A Shares.

17,000 A SHARES ARE NOW OFFERED FOR SUBSCRIPTION,

Payment for which is to be made as follows:—

10s. per Share .. .. on Application.
£2 per Share .. .. on Allotment.

And the balance as required at intervals of not less than Two Months, or the whole amount may be paid up on allotment, and interest will accrue from the date of payment.

THE REMAINING 5000 SHARES WILL BE ISSUED IF REQUIRED.

DIRECTORS.

* EDWARD BROOKE, Esq., J.P., 51, Nevern Square, S.W., and Pabe Hall, Conway, *Chairman.*
* ARTHUR BROOKE, Esq., Brockhurst, North Finchley, *Managing Director.*
* RICHARD SIMPSON, Esq., 4, Queen's Gardens, West Brighton.
* WILLIAM SPILLER, Esq., 66, Fitzjohn's Avenue, Hampstead.

(Sole Members of the Firm.)

EDWARD MUCKLOW, Esq., J.P., Elton Fold Works, Bury; Albyn Works, Glasgow; and 33, Faulkner Street, Manchester.
RICHARD JOHN FRISWELL, Esq., F.C.S., 115, Darenth Road, Stamford Hill.
HUGH DOMVILLE WYNTER, Esq., Howcaster Lodge, Higher Broughton, Manchester, *Manager of the Manchester Branch.*

* Will join the Board after allotment.

BANKERS.

Messrs. BROOKS & Co., 81, Lombard Street, London, E.C., and Messrs. CUNLIFFES, BROOKS, & Co., King St., Manchester.

BROKERS.

Messrs. W. G. BELLAIRS & Co., Stock Exchange, and 8, Draper's Gardens, E.C.

SOLICITORS.

Messrs. MORLEY & SHIRREFF, Gresham House, Old Broad Street, E.C.

AUDITORS.

Messrs. JOHN LITCHFIELD & SONS, 15, Spring Gardens, Manchester.

SECRETARY.

Mr. G. T. SMITH.

OFFICES.

Metropolitan Chambers, 10, New Broad Street, London, E.C.

The Company has been formed for the purpose of purchasing and taking over as a going concern as from the 1st January, 1886, the well-known business of Messrs. BROOKE, SIMPSON, and SPILLER (whose term of partnership expires this year), Patentees and Manufacturers of Aniline Dyes. Merchants, and Dry-salters, carrying on business at the Atlas Works, Hackney Wick, E.; Metropolitan Chambers, 10, New Broad Street, E.C.; 106, Portland Street, Manchester; 47, Peel Place, Bradford; and 30, Market Street, Huddersfield.

ATLAS WORKS, HACKNEY WICK.

These substantially-built and extensive Works are considered the largest and most efficient Aniline Dye Works in the Kingdom. The buildings comprise Laboratories, Offices, Warehouses, Store Rooms, extensive Vat Rooms, Melt Houses, Grinding and Crushing Mills, Drying Rooms, Boiler House (containing five 50 horse-power boilers), Packing Rooms, Water Tower, Well-house (with steam pump), Blacksmiths' and Joiners' Shops, &c., covering in all about two acres of land. The Artesian Well is 270 feet deep, and gives an unfailing supply of pure water, with an average discharge of about 22,000 gallons per hour. The Works are situate on the banks of the Lea Canal (connected with the Thames), 3¼ miles from the Bank of England, and comprise between five and six acres of Freehold Land. They have special facilities for deliveries inward and outward, and in water carriage, a canal frontage of about 550 feet, and a solidly-built loading wharf 232 feet long. They are bounded on the west by a well-formed road, under which the main culvert of the Metropolitan Board of Works runs, thus giving perfect drainage and free outlet for liquid refuse. The Plant and Buildings have been maintained in the highest state of efficiency, and are now being added to.

The output of solid colour for and the profits made in the year 1885 were the largest of the last four years.

The Vendors obtained Gold Medals at the Paris, London, and Inventions Exhibitions.

MANCHESTER WAREHOUSE, 106, PORTLAND STREET.

Large Stocks of Aniline Dyes are kept at this central Depot, where the vendors also carry on a remunerative Drysaltery Business under an efficient Staff and Management.

BRADFORD AND HUDDERSFIELD.

These Offices and Depots supply the immediate wants of Yorkshire customers, under the able management of Mr. Ernest Hickson.

LAND, BUILDINGS, PLANT, STOCKS, GOODWILL, &c.

The freehold land has been valued by Messrs. Fox and Bousfield, of 99, Gresham Street, E.C., at the sum of £16,150.

The Buildings, which are in excellent condition, and specially erected and adapted for the business, costing £37,103, have been taken at the figures shown in the last Balance-sheet, viz., £29,060, that is to say, less a depreciation of £8,043.

The Plant, Machinery, Engines, Boilers, Vats, Extractors, Condensers, &c., &c., the actual cost of which was £42,219, have been taken at the figures appearing in the last Balance-sheet, viz. £19,195, that is to say, less a depreciation on the cost of £23,024.

The Stocks of all finished products manufactured by the Vendors have been taken (and will be paid for in cash) at the prices charged in the last Balance-sheet, which are considerably less than the actual cost, and other Stocks and Raw Materials at and below cost.

It will thus be seen that any over valuation in the Land, Buildings, Plant, Stock, &c., has been carefully guarded against.

The consideration money to be paid for the Land, Buildings, Plant, and Goodwill, is the sum of £80,000, of which £40,000 will be paid by allotment to the Vendors of 2,000 A and 6,000 B fully paid up shares, and the Balance in cash.

AUDITORS' CERTIFICATE.

"15, Spring Gardens, Manchester,
20th February, 1886.

"Having regularly, every half-year, audited the books of Messrs. Brooke, Simpson, and Spiller, in London and Manchester, from the time they commenced business in 1868 up to the present, we hereby certify that from 1868 to 1877 exceptionally large profits were realised, the colours Magenta, Blue, and Violet being protected by Patents, the last of which expired in 1877; and that from the last-mentioned date to the end of 1885, the profits made and drawn have been such as would pay a dividend of over £12 per cent per annum on the share capital now proposed to be allotted.

(Signed) JOHN LITCHFIELD AND SONS,
Public Accountants."

GENERAL.

The Company acquire the property of the Vendors and take the profits as from the 1st January, 1886.

THE CHEMICAL NEWS.

Vol. LIII. No. 1373.

ON RADIANT MATTER SPECTROSCOPY:

Note on the Earth Yα.*

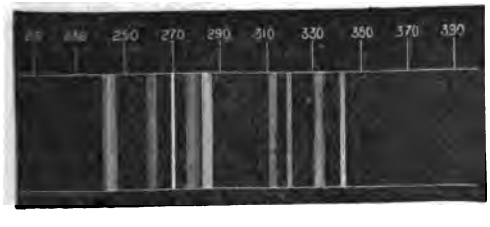
By WILLIAM CROOKES, F.R.S.

Among the samarskite earths which concentrate towards the middle of the fractionations there is one (or a group) which presents in the radiant matter tube a well marked phosphorescent spectrum differing from those I have already described.

The measurements of the bands and lines are given below:—

Scale of spectroscope.	λ.	$\frac{1}{\lambda^2}$.	Remarks.
10·325°	6446	2407	Approximate centre of a red band shaded off on the least refrangible side.
10·310°	6415	2430	Somewhat sharp edge of the red band.
10·185°	6189	2611	Approximate centre of a very faint orange band.
10·150°	6129	2662	Ditto Ditto.
10·130°	6094	2693	A sharp narrow orange-red line.
10·05°	5970	2806	Approximate centre of a narrow bright orange band. (Between this line and 2693 is a fainter semi-continuous orange band).
9·840°	5676	3104	Approximate centre of a narrow bright green band.
9·790°	5613	3174	Approximate centre of a narrow green band, not quite so bright as 3104.
9·690°	5495	3312	Approximate centre of a bright green band, wider than the other three green bands.
9·610°	5406	3422	Approximate centre of a narrow bright green band.

The accompanying figure gives the spectrum drawn to the $\frac{1}{\lambda^2}$ scale.



The earth giving the above spectrum, when sufficiently purified, presents all the characteristics of the earth discovered by Marignac, and provisionally called by him Yα.† Through the kindness of M. de Marignac I have been enabled to compare a specimen of Yα of his own preparation with the earth described above. The two earths agree in their chemical characteristics, and their phosphorescent spectra are practically identical.

No name has yet been given to this earth, as the discoverer appears to be in some doubt whether it is not identical with J. Lawrence Smith's earth mosandra.‡ A specimen of mosandra prepared by J. Lawrence Smith and sent me by M. de Marignac, gave a phosphorescent spectrum showing that it was compound, and that yttria was one of its constituents.

* A Paper read before the Royal Society, February 25, 1886.

VALUATION OF COMMERCIAL PHOSPHATES.

An Agreement arrived at between the Chemists of the Experimental Stations and the Manure Manufacturers of South Germany, upon a New Basis for Establishing the Commercial Value of Superphosphate and Precipitated Phosphate.*

By Prof. PAUL WAGNER, Ph.D.

For the last twenty years the need has been felt for establishing a basis for determining the commercial value of phosphatic manures other than that dependent upon the amount of total and soluble phosphoric acid which they contain. Superphosphates made from such phosphates as Lahn phosphorite have, in consequence of their containing so-called "reverted" phosphate, a higher agricultural value than that indicated by the amount of phosphoric acid soluble in water which they contain; and since phosphatic manures consisting exclusively of precipitated phosphates insoluble in water have lately been brought in increasing quantities into the market, the need for some other basis for valuing manures has become more and more pressing.

R. Fresenius, in conjunction with Neubauer and Luck, found, as is well known, in neutral ammonium citrate, a salt which in solution of a suitable strength, and at a given temperature and time for extraction, proved serviceable enough for separating the precipitated phosphates from that portion of phosphorite superphosphate insoluble in water. This method, however, did not satisfy the requirements of the manure trade, inasmuch as the manurial value of this (reverted) phosphoric acid compared to that of phosphoric acid soluble in water was unknown. In order to solve this question Petermann and Grandeau carried out some experiments, from the results of which they concluded that phosphoric acid soluble in citrate was of the same value as phosphoric acid soluble in water. This, however, was disputed in Germany, and the joint meeting of agriculturists and chemists held at Karlsruhe, in the year 1879, passed the following Resolution:—

"This meeting recognises the value of reverted phosphate for certain kinds of soil, and is in no way opposed to its determination, if required by the agriculturist or manufacturer, but considers that the experiments hitherto made do not furnish evidence sufficient to establish a valuation of reverted and precipitated phosphates."

Field experiments were now carried out, whilst at the same time a method was sought for to effect the determination of phosphoric acid soluble in the soil. Of the field experiments on the value of reverted and precipitated phosphates one has gradually become tired; they led to no issue, and it was impossible that they could do so. They have again been abandoned. Attempts to find a means, by merely laboratory operations, of determining phosphoric acid "soluble in the soil" have also proved fruitless, and it was indeed scarcely possible that they could succeed, since the very expression "phosphoric acid soluble in the soil" conveys no precise meaning, and moreover the means employed for this end could not themselves be held free from objection.

Ammonium citrate, it has been urged, is an entirely unsuitable material for determining phosphoric acid "soluble in the soil," as it dissolves only insignificant quantities of phosphoric acid out of Peruvian guano, bone-meal, and other similar manures which experience,

* Translated and contributed by H. H. B. Shepherd. From *Chemiker Zeitung*, 1886, x., 1, 2, 3.

has shown contain much effective phosphoric acid. Free 1 per cent citric acid, on the other hand, has been recommended as being far better, since it not only dissolves precipitated phosphate quite as well as does ammonium citrate, but it also takes up some 70 or 80 per cent of the phosphoric acid contained in bone-meal and raw Peruvian guano, and shows besides that ground raw phosphorite contains about 4 per cent of phosphoric acid soluble in the soil, which at any rate is correct, "for no agricultural chemist doubts that ground raw phosphorite used in large quantities *does* produce a certain amount of effect."

My own experiments have shown, however, that the manurial value of phosphoric acid soluble in 1 per cent citric acid varies, according as it is presented to the plants in the form of precipitated phosphate of lime, washed-out high-class superphosphate, or finely ground phosphate. Supposing the manurial value of the phosphoric acid soluble in 1 per cent citric acid to be represented by 100 in the case of precipitated phosphate of lime, its value in the case of washed-out high-class superphosphate would be represented by 160, and in the case of finely-ground raw phosphorite by 2. Citric acid is therefore not a suitable means for dissolving out phosphoric acid from the different commercial phosphates in a manner that will compare with that effected by the soil and the roots of plants.

In addition, however, to ammonium citrate and free citric acid, potassium oxalate has been proposed as a menstruum, thus showing to what precision the whole question has shaped itself in the practice of the manure trade! Besides phosphoric acid soluble in water the agriculturist can purchase now-a-days reverted phosphoric acid, phosphoric acid soluble in the soil, soluble in citrate or in citric acid, root-soluble, half-soluble, and precipitated-assimilable phosphoric acid; and he can have his analyses made by the methods of either Fresenius, Petermann, Halle (18th December, 1881), Tollens-Stutzer, or Liebig, or by the Anglo-Continental method; and if the agriculturist enquires what value is to be attached to these many-styled forms of phosphoric acid, he is told that this is not yet accurately known.

For some years I have been endeavouring to establish the ground-work necessary to throw some light upon this confused state of matters, and I proceeded upon the following lines:—If the agriculturist be offered pure superphosphate of lime, it ought to be no difficult matter for him to obtain an opinion upon its value. If the manure merchant's price for phosphoric acid soluble in water averages about 58 pf. per kilo., the farmer knows that he he will be right in paying 11 marks 60 pf. per 100 kilos. for a superphosphate containing 20 per cent of phosphoric acid soluble in water. It is different, however, in the case of high-class and phosphorite superphosphates or precipitated phosphate. The buyer has then no idea in what relation the value of the precipitated phosphoric acid stands to soluble phosphoric acid of pure superphosphate of lime. If such manures are to be freely saleable, one should be able to inform the agriculturist positively what percentage of phosphoric acid equal in manurial value to phosphoric acid soluble in water is contained therein. If this could be done the buyer would be in a position to tell exactly how much he could afford to pay for the manure and how it should compare as regards cost with pure superphosphate of lime. For the requirements of the manure trade, therefore, an analytical method is wanted which will give the phosphoric acid of phosphorite superphosphate, of high-class superphosphate, and of precipitated phosphate, in their equivalents of phosphoric acid soluble in water, a method which will show how much per cent of phosphoric acid of the manurial value of phosphoric acid soluble in water is present, or, in other words, the manurial value of the material expressed in terms of phosphoric acid soluble in water. Or, if we call such phosphoric acid simply "soluble" phosphoric acid, and agree that by this term we are to understand phosphoric acid of the same manurial value as phosphoric acid soluble in water, then the question presents itself as follows:—

1. By means of manurial experiments to fix the relative manurial values of certain phosphatic manures expressed in terms of "soluble" phosphoric acid, *i.e.*, in terms of phosphoric acid of the same manurial value as phosphoric acid soluble in water.
2. To find an analytical method which shall furnish results agreeing exactly with the percentage of "soluble" phosphoric acid obtained by the manurial experiments.

This question has been my study during a long series of years. As regards the carrying out of my experiments, however, and the details which had to be taken into consideration, I must here confine myself to merely cursory references.

The manures which I used were the following:—

1. Pure superphosphate of lime.
2. A commercial precipitated phosphate of lime, prepared by precipitation in a strongly acid solution, and termed dicalcium phosphate.
3. A commercial precipitated phosphate of lime, precipitated with excess of lime, and termed tricalcium phosphate.
4. A washed-out high-class superphosphate.
5. A washed-out phosphorite superposphate.
6. Finely ground raw phosphorite.

I thought it unnecessary to include also the superphosphates 4 and 5 in the original unwashed-out condition, as, in the presence of so overwhelming an amount of phosphoric acid soluble in water, the effect of the precipitated phosphate contained in them would not have been sufficiently marked. The washing-out of the superphosphates was itself a matter for careful consideration, inasmuch as variations, both qualitative and quantitative, in the precipitated phosphoric acid, arise according as the wash-water at first poured upon the superphosphate is allowed to filter faster or slower through the mass. The quantity of the wash-water used and the length of time occupied by the washing have also their influence, and the variations thus caused would be sufficient to affect the results of the manurial experiments to such a degree as to render the carrying of them out in practical working inadmissible. In the examination of this question I now started with the following consideration:—It is necessary in superphosphates to distinguish between—

1. The phosphoric acid which goes into solution on treating 20 grms. of superphosphate with 1 litre of water for two hours, and—
2. The phosphoric acid which remains undissolved in the residue.

The manurial value of the phosphoric acid referred to under 2 must be obtained by means of manurial experiments, and a suitable material for such experiments can be prepared by digesting 20 grms. of superphosphate in 1 litre of water, or 200 grms. in 10 litres, for two hours, with frequent shaking, collecting the residue upon a filter, and, without further washing, allowing it to dry at the ordinary temperature of the air. In this way I produced the so-called washed-out superphosphates. I must further remark that I carried out the experiments in zinc vessels holding about 16 kilos. of earth, and that I experimented upon three kinds of soil, viz., sandy soil poor in lime, loamy soil containing lime, and Rhenish-Hessian soil rich in lime. The moisture in the soil was kept as constant as possible, and at about the medium percentage (10 to 15). The crops upon which I experimented were barley, oats, peas, and grass.

I have already frequently expressed myself concerning the peculiarities of the results obtained by my method, but I now briefly communicate the following:—

1. The phosphoric acid found in bicalcium phosphate by the Fresenius method proved equal in value to 100 per cent of phosphoric acid soluble in water.

2. The phosphoric acid found in the tricalcium phosphate by the Fresenius method proved equal in value to 75 per cent of phosphoric acid soluble in water.
3. The phosphoric acid found in the washed-out high-class superphosphate and phosphorite superphosphate by the Fresenius method proved, on the average, equal in value to 70 per cent of phosphoric acid soluble in water.

I must here remark that these data have reference to the action which the phosphates, applied in the spring at seed-time, exercised on the crops; the so-called "after-effects" of the phosphates are therefore left out of consideration. Arrangements for carrying out the experiments so as to show indubitably the after-effects of the manures have only been at my disposal since the beginning of the year 1885, and I have naturally not yet been able to bring the work in connection with them to a conclusion.

4. The results of the manurial experiments give the following percentages of "soluble" phosphoric acid,—*i. e.*. of phosphoric acid equal in value to phosphoric acid soluble in water, contained in the manures used:—

	"Soluble" phos. acid.
Bicalcium phosphate	30·6 per cent.
Tricalcium ,, ...	16·4 ,,
Washed-out high-class superphosphate	17·9 ,,
Washed-out phosphorite superphosphate	3·0 ,,
Finely-ground raw phosphorite ..	0·1 ,,

Having obtained these results the first part of my task was accomplished. In five different phosphatic manures the percentages of "soluble" phosphoric acid was obtained, and it still remained to find a menstruum which under the same circumstances would dissolve phosphoric acid out of each manure in the above proportions,—that is to say, 30·6 per cent out of bicalcium phosphate, 16·4 per cent out of tricalcium phosphate, and 17·9 per cent out of washed-out high-class superphosphate.

After many experiments with all possible organic acids I arrived at the same conclusion as Tollens and Stutzer, viz., that of all organic acids citric alone can be considered admissible; but even this acid, or at any rate the exclusive use of it, proved unsuitable, since its action upon phosphate of iron and alumina is too weak in comparison with its action upon phosphate of lime. I therefore made experiments with its ammonium salts, and came to the same opinion as Fresenius, viz., that of all salts of citric acid only the ammonium citrate can be considered available. It followed from this that in a suitable mixture of neutral ammonium citrate and free citric acid the properties of both would combine to form a solvent available for the various phosphates. A few preliminary experiments confirmed this supposition.

Now that the preliminaries of the required method had been decided upon, I determined to take into consideration the details of the process and all the practical requirements necessary for a method intended to further the object in view.

I essentially kept in mind the following considerations:—

1. The method must allow of superphosphate being treated directly, *i.e.*, without having first to remove the phosphoric acid soluble in water.
2. In order that there may be no difficulty in obtaining a representative sample, sufficient of the material under examination must be taken for extraction (at least 5 grms. per ½ litre).
3. The length of time to be decided upon for the extraction must be such that in the event of 30 or 40 superphosphates being in hand at once they can be dealt with without inconvenience. The longer the time agreed upon for extraction, the less likely can any deviations from such time affect the results, and provided it be observed within an hour one way or the other, I recommend as most convenient that the period for extraction be from one day to the next.
4. Also the prescribed degree of temperature must be such as to render its maintenance easily controlled, so that deviations may not lead to differences. The so-called temperature of the room, 13° to 18° C., is most to be recommended.
5. The method must admit of the substance being rubbed fine, for in no other way can uniformity in the results be obtained.
6. A sufficient quantity of the menstruum must be available for rubbing up the substance. 100 c.c. of citrate solution are not enough for conveniently dealing with 5 grms. of substance.
7. The determination of the phosphoric acid must be made in the extract and not indirectly in the residue, and the phosphoric acid must be precipitated by molybdenum, so that the results turn out exact and reliable.

Having regard to these seven essentials I arrived, after many experiments, at the following method:—5 grms. of superphosphate or precipitated phosphate are rubbed up with some dilute citrate solution, poured into a half-litre flask, made up to the mark with dilute citrate solution, allowed to stand about 18 hours at the temperature of the room (13° to 18° C.), with frequent shaking, and then filtered.

50 c.c. of the filtrate are then treated with molybdenum solution, so that 1 c.c. shall be present for every milligrm. of phosphoric acid, and to this mixture as much concentrated ammonium nitrate solution is added as would amount to a fourth of the mixture. After standing for about 20 minutes in the water-bath it is allowed to cool and is then filtered; the precipitate is washed on to the filter with a dilute solution of ammonium nitrate, a hole made in the filter, and the precipitate washed back into the beaker with dilute ammonia (2½ per cent); the filter is well washed, and to the ammoniacal solution 20 c.c. of magnesia mixture are added drop by drop with constant stirring. After standing for one hour the precipitate is filtered off, washed with dilute ammonia (2 per cent) dried, and ignited.

Preparation of the necessary Solutions.

1. Concentrated citrate solution. 150 grms. of citric acid are placed in a litre flask, dissolved in water, and neutralised with ammonia. To the neutralised solution 10 grms. of citric are added, and the solution made up to the mark with water.
2. Dilute citrate solution. 1 volume of concentrated citrate solution is mixed with 4 volumes of water.
3. Concentrated ammonium nitrate solution. 750 grms. of ammonium nitrate are dissolved in water and the solution diluted to a litre.
4. Dilute ammonium nitrate solution. 100 grms. of ammonium nitrate are dissolved in water and the solution diluted to a litre.
5. Molybdenum solution. 150 grms. of ammonium molybdate are dissolved in water, the solution diluted to a litre, and mixed with a litre of nitric acid of sp. gr. 1·2.
6. Magnesia mixture. 110 grms. of pure crystallised magnesium chloride and 140 grms. of ammonium chloride are dissolved in 1300 c.c. of water and 700 c.c. of ammonia (8%).

I now give the results I obtained by this method in comparison with those calculated from the mean results of the manurial experiments.

These results agree satisfactorily, and it may be reasonably accepted that my method gives figures which show sufficiently near the truth the agricultural value of phosphorite superphosphate, high-class superphosphate, and

"Soluble" Phosphoric Acid.

	Calculated from the results of the manurial experiments.	Obtained by analysis.
	Per cent.	Per cent.
Bicalcium phosphate	30·6	29·3
Tricalcium ,, ...	18·0	19·1
Washed-out high-class superphosphate	17·9	16·9
,, phosphorite ,,	3·0	3·3
Finely ground phosphorite	0·1	0·6

precipitated phosphate in terms of phosphoric acid soluble in water.

It is now self-evident that the method could be further devoloped, and had not external pressure been brought to bear upon me I would have hesitated before proposing to introduce it at once into the practice of the manure trade. Requests to make determinations of phosphoric acid soluble in citrate in the above-named manure materials have, however, been so frequent of late at the experimental stations at Bonn, Darmstadt, Speier, and Wiesbaden that the immediate introduction of the method appeared very necessary.

At a meeting of those manure manufacturers of South Germany chiefly interested, held at Mayence on Nov. 30th, 1885, and called at the instance of the experimental stations of Bonn, Darmstadt, Marburg, Speier, and Wiesbaden, I found myself called upon to report upon the work I had carried out and to apply to them to test my process as to what extent in the various laboratories concordant results could be obtained. In consequence of this request the meeting appointed representatives of four experimental stations and four manure works as a commission, which carefully drew average samples of 8 different phosphatic manures and distributed them amongst 12 laboratories, and at a further meeting held at Mayence, on December 19th, reported upon the results obtained.

From the returns furnished by 11 of the laboratories it was ascertained that the variations between the separate results and the mean averaged as follows:—

	Per cent "soluble" phosphoric acid.
With high-class superphosphate .. I.	= ± 0·27
,, ,, .. II.	= 0·38
With phosphorite ,, .. III.	= 0·30
,, ,, .. IV.	= 0·32
	Mean = ± 0·32

Against this the variations in the determinations of the phosphoric acid soluble in water made by the same chemists amounted to—

	Per cent phosphoric acid soluble in water.
With high-class superphosphate .. I.	= ± 0·39
,, ,, .. II.	= 0·36
With phosphorite ,, .. III.	= 0·13
,, ,, .. IV.	= 0·18
	Mean = ± 0·26

From this we see that the mean differences in the determinations of the "soluble" phosphoric acid exceed those of the phosphoric acid soluble in water by only 0·6 per cent. The representatives of the manure manufacturers and those of the experimental stations of Bonn, Darmstadt, Speier, and Wiesbaden have therefore agreed unanimously to accept this method for the analysis of all superphosphates from January, 1886, and in consequence thereof to advertise in their price lists a guaranteed percentage of "soluble" phosphoric acid in the different superphosphates.

In the case of Thomas precipitated phosphate the results obtained were not sufficiently concordant, and the commission was requested to look closer into the matter and to report again in due course.

It is now to be hoped that the convention which met at Mayence, as well as all other manure manufacturers and agricultural chemists, will co-operate in this movement, in order that through the instrumentality of this agreement this most desirable reform in the trade in precipitated or "reverted" phosphates may be carried out in the interests of buyers and sellers alike.

CERIUM OXIDE, YTTRIA, GLUCINA, AND AMMONIUM CHLORIDE IN DILUVIAL CLAY.

By Dr. J. H. STROHECKER.

At Hainstadt, not far from Seligenstadt, there extends a thick diluvial bed of clay, derived chiefly from syenite, the several layers of which differ remarkably even in their outward aspect. The two upper layers (I. and II. *a*) give the following composition:—

Layer I.

Silica	47·5444
Titanium oxide	traces
Alumina	24·5937
Glucina	6·4399
Ferric oxide	0·9190
Cerium hydroxide	13·4214
Lanthanum oxide	0·8576

Besides calcium sulphate and carbonate, magnesia, phosphoric acid, potassa, and soda.

Layer II. *a* showed—

Silica	58·3331
Alumina	11·7607
Glucina	5·3833
Ferric oxide	0·6356
Cerium hydroxide	9·4012
Didymia	0·8474
Lanthanum oxide	2·6536
Yttria	1·6949

Besides magnesia, phosphoric acid, lime, calcium sulphate, potassa, soda, ammonium chloride (0·0529 per cent), and lignite.

The ceria and yttria betray, as their origin, orthite, which occurs in the syenite at Weinheim in the Odenwalde. The high percentage of Ce_2O_3 allows an inference as to the abundance of this mineral in the original rock.

The stratum No. I. extends below arable soil over the entire Hainstadt clay deposit, and its colour is of different degrees of intensity in different places,—light flesh-colour, pale and dark cinnamon,—so that the colouring-matter, cerium hydroxide, must be variously plentiful in different parts. The bricks made from this clay are a pale orange-yellow (from cerium oxide) if lightly burnt; but if strongly burnt they are of a leather-colour, in contrast to the ordinary ferric-oxide bricks. It is known that Ce_2O_3 takes a leather-colour, or even a silver-grey at a white-heat.

The stratum No. II. is divided into two layers, *a* and *b*. The former is coloured black by lignite, and gives lemon-coloured bricks, since Ce_2O_3 is reduced by the carbon on ignition to Ce_3O_4. The bricks of *b* are orange-red to orange-yellow.

The blue stratum, No. III., contains cerium oxide, though in a smaller proportion than the fwo former, and yields bricks of a paler orange than II. *b*.

Didymium oxide has not yet been detected with certainty in No. I., either by the spectroscope or by chemical reactions, though rose-coloured spots in ignited masses of the clay indicate its presence. It is found along with yttria in II. *a*, whilst lanthanum oxide is found in both. The Hainstadt cerite-clays are characterised by their proportion of glucina, the almost constant companion of the cerite oxides. The precipitate of cerium hydroxide with

ammonia and soda has exactly the appearance of iron hydroxide, though in a finely-divided state it appears of a cinnamon-brown, inclining to orange. The similarity of the two precipitates is so great that cerium hydroxide has probably often been taken for ferric hydroxide, especially as the ferrocyanide precipitates of both are scarcely, if at all, distinguishable. Cerium is most easily recognised by the colour of its oxides, the orange-red Ce_2O_3, the lemon-coloured Ce_3O_4, the sky-blue compound of cerous oxide and potassium, by its precipitate with oxalic acid, the formation of cerium-ammonium chloride, and its solubility in caustic potassa. The three cerium oxides have been detected in the ash of plants as early as 1880.—*Journ. f. Prakt. Chemie* (1886, p. 132).

LONDON WATER SUPPLY.

REPORT ON THE COMPOSITION AND QUALITY OF DAILY SAMPLES OF THE WATER SUPPLIED TO LONDON FOR THE MONTH ENDING FEBRUARY 28TH, 1886.

By WILLIAM CROOKES, F.R.S.,

WILLIAM ODLING, M.B., F.R.S., F.R.C.P., Professor of Chemistry at the University of Oxford.

and C. MEYMOTT TIDY, M.B., F.C.S., Professor of Chemistry and of Forensic Medicine at the London Hospital; Medical Officer of Health for Islington.

To COLONEL SIR FRANCIS BOLTON, *Water Examiner, Metropolis Water Act*, 1871.

London, March 7th, 1886.

SIR,—We submit herewith the results of our analyses of the 163 samples of water collected by us during the past month, at the several places and on the several days indicated, from the mains of the seven London Water Companies taking their supply from the Thames and Lea.

In Table I. we have recorded the analyses in detail of samples, one taken daily, from February 1st to February 28th inclusive. The purity of the water, in respect to organic matter, has been determined by the Oxygen and Combustion processes; and the results of our analyses by these methods are stated in Columns XIV. to XVIII.

We have recorded in Table II. the tint of the several samples of water, as determined by the colour-meter described in a previous report.

In Table III. we have recorded the oxygen required to oxidise the organic matter in all the samples submitted to analysis.

Of the 163 samples examined, the whole were found to be perfectly clear, bright, and well filtered.

The general character of the water supplied to the Metropolis during the month of February did not differ appreciably, in respect to the small proportion of organic matter habitually present, from that of the supply furnished now for some months past. Thus, the mean amount of organic carbon found in the Thames-derived supply for the month was 0·172 part in 100,000 parts of the water, as against a mean amount of 0·183 part in January, and of 0·170 part in December, corresponding to about three-tenths of a grain of organic matter per gallon.

The degree of colour-tint, somewhat in excess during the heavy floods of November, has since shown a steady continuous decrease. Moreover, since the period of these floods not a single daily sample has been met with to which even the expression "very slightly turbid" would apply; and this notwithstanding the exceptional and persistent low temperature of the last three months, a condition affecting appreciably the viscosity of the water, and in other ways impeding the processes of filtration.

We are, Sir,
Your obedient Servants,

WILLIAM CROOKES.
WILLIAM ODLING.

THE DIASTATIC ACTION OF SALIVA, AS MODIFIED BY VARIOUS CONDITIONS, STUDIED QUANTITATIVELY.*

By R. H. CHITTENDEN and HERBERT E. SMITH.

(Continued from p. 124.)

Influence of Proteid Matter on the Diastatic Action of Saliva in Neutral Solutions.

IT was formerly demonstrated by one of us† that the presence of 1 per cent peptone tended to increase the diastatic action of saliva in a neutral solution to such an extent that on an average about 4 per cent more starch was converted into sugar during 45 minutes at 40° C.; this with 25 c.c. of saliva in 100 c.c. of the digestive mixture. This effect we attributed to a direct stimulating action on the part of the proteid matter. Langley and Eves,‡ however, object to this conclusion, although they bring forward no facts to prove the contrary. Considering that litmus will not detect less than 0·001 per cent acid or alkali, they state that there may be in the neutralised fluid an excess of acid or alkali to this extent, and if, as may well be the case, ptyalin acts best in a neutral solution, the effect of the peptone might be due to its putting *hors de combat* the slight excess of acid or alkali which remains on apparent neutralisation. But, as Langley himself has shown, the proteid matter naturally present in 25 c.c. saliva, or even much less, is far more than sufficient to combine with and render inert any such amount of free acid or alkali. We see no other possible explanation of the action of peptones on the diastatic action of saliva in a neutral solution than a direct stimulation of the ferment. Moreover, Langley and Eves have found that when neutralised saliva is diluted a hundred times, peptone is still able to increase the rate at which it converts starch into sugar, from which they are forced to conclude that the small amount of acid or alkali which may be present, cannot exert, in such a dilution, any retarding influence. We present the following additional results confirmatory of our previous experiments.

In our present experiments we have, however, used much less saliva, and also smaller percentages of peptone.

SERIES XI.

20 c.c. of filtered saliva were neutralised, and then diluted to 100 c.c.

0·8 grm. of pure albumen-peptone was dissolved in water, made exactly neutral with Na_2CO_3, and the solution diluted to 100 c.c.

10 c.c. of the diluted saliva were employed in each digestion, and of the peptone solution quantities equivalent to 0·05, 0·1, and 0·2 grm. of peptone. Length of digestion, 30 minutes.

Per cent peptone.	Wt. Cu in one-eighth.	Total amount sugar.	Starch converted.
0	0·0834 grm.	0·3400 grm.	30·61 p.c.
0·05	0·0875	0·3568	32·11
0·10	0·0868	0·3544	32·01
0·20	0·0873	0·3560	32·04

Here, with the smaller amount of ferment, the increase is not so great as with the larger quantity of saliva and with the longer period of digestion; still the amount of starch converted is increased on an average about 1·50 per cent. It is interesting to note that under these conditions the full effect of the proteid matter is produced by even 0·05 per cent. Langley and Eves found the maximum effect with saliva ten times diluted to be produced by about 0·1 per cent peptone. In our experiment, however, the dilution of the saliva in the digestive mixture is 1 : 50.

‡ *Journal of Physiology*, vol. iv., No. 1.

Influence af Proteid Matter on the Diastatic Action of Saliva in Alkaline Solutions.

It was previously demonstrated by one of us that the presence of 1 per cent peptone in a digestive mixture containing 25 per cent saliva and 0·3 and 0·15 per cent sodium carbonate respectively, tended to nearly double the diastatic action, bringing it up almost to the action of saliva unmixed with alkaline carbonate.

We give here a few additional experiments bearing on this point.

The very noticeable difference in the action of small percentages of sodium carbonate on the diastatic activity of moderately dilute and very dilute saliva at once suggests the possibility of some connection between the dilution and the reduced percentage of proteid matter. What, now, is the influence of small amounts of peptone on very weak alkaline solutions of saliva? We will give the results of one series of experiments in answer to this question.

SERIES XII.

20 c.c. of saliva with an alkalinity equal to 0·110 per cent sodium carbonate were diluted to 100 c.c.; 10 c.c. of the diluted saliva were used in each digestion of 100 c.c.; consequently the alkalinity of the digestive mixture was equal to 0·0022 per cent sodium carbonate. Neutral peptone was added in varying quantities. The mixtures were warmed at 40° C. for 30 minutes.

Per cent peptone.	Wt. Cu in one-eighth.	Total amount sugar.	Starch converted.
0	0·0761 grm.	0·3104 grm.	27·94 p. c.
0·05	0·0823	0·3352	30·18
0·10	0·0841	0·3424	30·82
0·20	0·0853	0·3480	31·33

The same saliva neutralised converted 30·61 per cent of the starch into sugar; consequently the neutral peptone (0·2 per cent) caused the alkaline saliva to show a diastatic action considerably greater than the neutral saliva, but not equal in this case to the action of the same percentage of peptone on the neutralised saliva. Compare Series XI., made with the same saliva.

Still other experiments of the same nature have shown like results, and even more marked. Thus, while neutral saliva without peptone converted in one instance 18·16 per cent starch into sugar, a like quantity of the normally alkaline saliva (=0·002 per cent Na_2CO_3 in the digestive mixture) with 0·1 per cent peptone converted 31·90 per cent starch into sugar.

Increasing the percentage of carbonate to a point where previous experiment had shown almost complete stopping of the action of the ferment, it was found that 0·1 per cent of neutral peptone would, in the above dilution, bring the diastatic action up, almost to that of the neutral saliva.

SERIES XIII.

Thus 20 c.c. of saliva were neutralised and diluted to 100 c.c., 10 c.c. used in each digestion.

	0 Na_2CO_3 0 Peptone.	0·005 p c. Na_2CO_3 0 Peptone.	0·005 p.c. Na_2CO_3 0·10 p.c. Peptone.
Wt. Cu in 1-8th	0·0803 grm.	0·0181 grm.	0·0708 grm.
Total amt. sugar	0·3272	0·0800	0·2896
Starch converted	29·45 p. c.	7·20 p. c.	26·07 p.c.

With 0·025 and 0·050 per cent sodium carbonate, 0·1 per cent peptone availed but little: there was slight diastatic action, but not enough sugar formed to make the determination of it of any value. These results would seem to indicate that one action of the peptone in an alkaline solution is to combine with the alkaline carbonate and form a compound of quite different power: thus with 0·050 per cent sodium carbonate a corresponding larger percentage of peptone is required to increase the diastatic power. In addition to this action, however, there is still manifest the direct stimulating action of the proteid matter on the ferment; seen in one case in the increased percentage of sugar formed in the alkaline solution over the amount formed in neutral solution by the same saliva under like conditions.

As to the union of peptone and the alkaline carbonate we have a strong indication of a combination, in that the presence of peptone tends to diminish somewhat the destructive action of small percentages of sodium carbonate in diluted saliva.

Thus, while 10 c.c. of neutralised dilute saliva (1:5), warmed for one hour with 0·05 per cent sodium carbonate, converted after neutralisation 25·05 per cent starch into sugar, the same amount of saliva warmed for the same length of time with the same percentage of sodium carbonate, plus 0·4 per cent peptone, converted after neutralisation 32·68 per cent of the starch.

The peptone present had evidently in some way prevented the destructive action of the alkaline carbonate, and the most plausible explanation seems to be the probable formation of an alkaline proteid body.

(To be continued.)

ANALYSES OF COMMERCIAL FERTILISERS.*

(Continued from p. 126.)

MR. GLADDING read the following paper, which was ordered to be spread upon the minutes:—

"*On the Determination of Citrate-soluble Phosphoric Acid in Natural Guanos.*" By THOMAS GLADDING, A.M.

In the method adopted by the Association of Official Agricultural Chemists, at Philadelphia, 1884, for the estimation of the reverted or citrate-soluble P_2O_5 in superphosphates, 2 grms. of the fertiliser are digested with 100 c.c. of the solvent.

This amount of solvent is regarded as ample for the solution of all strictly precipitated P_2O_5 that may be present. It undoubtedly at the same time dissolves a considerable portion of the strictly insoluble P_2O_5 that is contained in the superphosphate; but this is unavoidable, and, as all superphosphates are treated exactly alike, no injustice is done by this course.

The agricultural chemist is frequently called upon, however, to determine the so-called available or citrate-soluble phosphoric acid in the many natural guanos that are in the market. These guanos have not been treated with acid, and do not contain, strictly speaking, any reverted phosphate. What, then, it may be asked, is the object of determining the citrate-soluble in these forms of fertiliser? Obviously there is only one object, and that is to determine their degree of solubility as compared with one another and with artificially treated manures.

In determining the citrate-soluble P_2O_5 in this form of fertiliser, the Association has not distinctly stated the amount of fertiliser that must be used to every 100 c.c. of citrate solution. In consequence considerable latitude is exercised at the present time in this direction, some analysts employing 2 grms. to 100 c.c. solvent, while others use the much smaller quantity of 0·4 grm. to 100 c.c. solvent, causing thereby much confusion and dissatisfaction.

The object of determining the available or citrate-soluble in these natural guanos is, as has been said, to furnish a means of comparison as to their relative solubility. Thus in my paper "On the Reversion of Phosphoric Acid" (*Am. Chem. Journal*, vol. vi., No. 1) I found that by treating several guanos in the same way exactly (2 grms to 100 c.c. cit. sol.) I obtained, as citrate-soluble, respectively—

* From the *Proceedings* of the Second Annual Meeting of the Association of Official Agricultural Chemists, at Washington, D.C., September 1, 1885. Edited by Charles W. Dabney, Jun., Ph.D., North Carolina Agricultural Experiment Station, Secretary.

Oruba guano	2·09 per cent.
Orchilla guano	4·81 ,,
Mona Island guano	6·82 ,,
Peruvian guano	13·14 ,,

This gives us at once a rough comparison of these guanos. Peruvian, for instance, is at least six times more easily soluble than Oruba guano.

Right here arises a strong objection to the use of 0·4 grm. to 100 c.c. solvent, or rather two objections.

First. In the above tests all but a trace of the Peruvian guano was dissolved. Now had I used 0·4 grm. of each my results on the Peruvian would consequently be the same as above, for I could not dissolve out more than there is present, while the Orchilla would have come up to the same amount at least as the Peruvian, if not more, and the Oruba would probably give at least 6 or 7 per cent. As a result all sense of comparison would be lost, and the comparative test be valueless. We may lay it down as an axiom—*A unit of comparison must not be greater than any one of the objects compared.*

Second. In the second place these guanos will inevitably be compared with superphosphates. Thus a large lot of Orchilla guano, tested by using 0·4 grm. to 100 c.c. citrate-solution, gave total P_2O_5 16·42; available or citrate-solution 13·05 per cent. An acid phosphate analysed at the same time was reported as containing total P_2O_5 14·59; available, 10·94. Comparing these reports side by side we have—

	Acid phosphate.	Guano.
Total P_2O_5 ..	14·59 per cent.	16·42 per cent.
Available ..	10·94 ,,	13·05 ,,
Insoluble ..	3·65 ,,	3·37 ,,

In other words, the guano is a far more valuable article than the acid phosphate,—a most erroneous conclusion.

But a direct argument for the use of 0·4 grm. of these guanos to 100 c.c. solvent is made as follows:—

Manufacturers mix these guanos with superphosphates in very small proportions, say 10 and 20 per cent. When, therefore, 2 grms. of such mixture is digested with 100 c.c. solvent we are employing only 0·2 and 0·4 grm. of the guano, respectively, to 100 c.c. citrate-solution. A much larger amount is dissolved than when 2 grms. are used to 100 c.c. Consequently, when analysing the guano before mixing with the acid phosphate, the same amount, 0·4 grm., should be taken.

In answer to this argument, it is true that where 0·4 grm. of such a guano is digested alone with 100 c.c. citrate-solution a very much larger percentage of P_2O_5 is dissolved than when 2 grms. are thus treated. But when this 0·4 grm. is mixed with 1·6 grms. of a superphosphate there remains, after washing out the soluble, a large amount of reverted and insoluble phosphates, as also a large amount of $CaSO_4$, organic matter, &c. Now in the presence of these foreign matters we have found that the action of the citrate on the $\frac{1}{5}$ grm. of admixed guano is greatly weakened, and is very nearly represented by the action on the 2 grms. of guano when treated alone with 100 c.c. solution. For some years our firm has analysed Orchillas, Curaçaos, &c., for available, using 2 grms. and 100 c.c. for manufacturers. The mixtures of these guanos with acid phosphates have analysed almost exactly what was expected by calculation from the analyses of the component parts.

To convince ourselves, however, on this point, we have taken a sample of Orchilla guano, mixed it with a superphosphate, and analysed mixture, with the following results:—

Analysis of Superphosphate.

(2 grms. to 100 c.c. cit.-sol.)

Total P_2O_5	11·55 p. c.
Available P_2O_5	9·75
Insoluble P_2O_5	1·80

(First mixture.)

1·8 grms. superphosphate.
0·2 grm. guano = 10 per cent guano.
Insoluble obtained, 3·00 per cent.

Analysis of Guano.

	(2 grms. to 100 c.c.)	(4 grms. to 100 c.c.)
Total P_2O_5 ..	16·42 p. c.	16·42 p. c.
Available P_2O_5	5·87	13·05
Insoluble P_2O_5	10·55	3·37

(Second mixture.)

1·6 grms. superphosphate.
0·4 grm. guano = 20 per cent guano.
3·88 per cent.

Calculating the theoretical results from analyses of components:—

(1) When 2 grms. guano were used to 100 c.c.:—

(First mixture.)

	Per cent.		Per cent.
1·8 grms. superphosphate	× 1·8	insoluble	0·0324 grm.
0·2 grm. guano	× 10·55	insoluble	0·0210
			2) 0·0534
			2·67

(Second mixture.)

	Per cent.		Per cent.
1·6 grms. superphosphate	× 1·8	insoluble	0·0288 grm.
0·4 grm. superphosphate	× 10·55	insoluble	0·0420
			2) 0·0708
			3·54

That is, the insolubles actually obtained were 0·23 per cent, and 0·34 per cent higher than they should have been by calculation, thus showing that the availables in the guano were rather above than under the truth.

(2) When 0·4 grm. guano was used to 100 c.c.:—

(First mixture.)

	Per cent.		
1·8 grms. superphosphate	× 1·8	.. ..	0·0324
0·2 grm. guano	× 3·37	.. ..	0·0067
			2) 0·0391
			1·95

(Second mixture.)

	Per cent.		
1·6 grms. superphosphate	× 1·8	.. ..	0·0288
0·4 grm. guano	× 3·37	.. ..	0·0134
			2) 0·0422
			2·11

If we had reported this guano to the manufacturer as containing 13·35 per cent available, 3·37 per cent insoluble, he would have calculated on getting these last figures on his mixtures, viz., 1·95 and 2·11 per cent. When on analysis his mixtures actually returned 3 per cent, and 3·54 per cent insoluble, an explanation would be in order. The above analyses were made just at the time of mixture. A mixture of 10 per cent guano and 90 per cent superphosphate was allowed to stand four days. The sample was then analysed, and even ground to a fine paste, instead of using a rubber pestle, as usual, so as to obtain as low an insoluble as possible. The analysis gave insoluble 2·80 per cent.

In conclusion, we believe the only just and safe course to be the employment in all cases of the same standard of measurement, the use of 2 grms. of all classes of fertilisers to 100 c.c. of citrate solution.

To avoid difficulties arising from washing we use the following method:—After digesting 30° minutes at 65° C. the flask is filled to the mark with water, cooled quickly, filtered till perfectly clear, an aliquot evaporated to dryness, ignited with magnesium nitrate to P_2O_5, estimated as usual. The reverted in superphosphates might be determined directly in the same way.

Laboratory of Stillwell and Gladding.

By consent of the Association Prof. W. C. Stubbs read the following paper, by Mr. B. B. Ross, an assistant-chemist in the laboratory of the Alabama State Chemist, and it was ordered to be spread upon the minutes.

"*Method of Determining Citrate-Soluble Phosphoric Acid by Elimination of Citric Acid.*" By B. B. Ross, Assistant in State Laboratory, A. and M. College, Auburn, Ala.

This method depends upon the precipitation of citric acid in neutral solutions by addition of calcium chloride, the solution being heated nearly to boiling in order to render the precipitate insoluble in the ammonium chloride formed. In the determination of citrate-soluble phosphoric acid by this method, the method adopted by the Association is followed as far as the filtration of the ammonium citrate solution, in which the residue from the treatment with water has been digested for half an hour at 65° C.

The following scheme of analysis was followed in arriving at the appended results:—

Carefully collect the filtrate and washings resulting from the ammonium citrate treatment; transfer to a cylinder, and dilute to 200 c.c.; mix well.

Take 50 c.c. and dilute to about 100 c.c.; add calcium chloride solution in excess, and heat nearly to boiling, stirring vigorously all the while after the solution begins to cloud; apply the heat very cautiously towards the last, and continue stirring assiduously until a copious white precipitate of calcium citrate is formed and well coagulated. The precipitate will subside immediately. Filter; wash well with very hot water, first by decantation and afterwards on the filter. To the filtrate add ammoniac hydrate in very slight excess; add 15 grms. of dry ammonium nitrate, and precipitate the phosphoric acid with molybdic solution. Proceed as with total phosphoric acid.

Calcium chloride solution: this is a neutral 20 per cent solution of calcium chloride.

It may be necessary to take an aliquot representing more than one-half grm. on account of a small percentage of citrate-soluble being present in the substance (less than 2 per cent), thus necessitating the addition of a larger quantity of calcium chloride. The calcium citrate precipitate is somewhat bulky, but if large filters are used it will not prove too unwieldy, and can be filtered and washed with great facility.

This process consumes very little time, and precipitation of the phosphoric acid with the molybdic solution can be accomplished within fifteen minutes after measuring an aliquot part of the filtrate obtained by treatment with ammonium citrate. Several experimental analyses of fertilisers have been made by this method, and all tests made by the above scheme have resulted satisfactorily. However, the limited amount of time employed in the examination of the subject has precluded a thorough investigation.

The following samples were subjected to analysis, and the results given below verified by additional tests.—

No. 1. South Carolina phosphate, sent by Prof. Jenkins for the purpose of testing the Association method.

No. 2. Navassa phosphate, also from Prof. Jenkins. In this sample, as shown by duplicate determinations, a portion of the phosphoric acid has reverted since our analysis was made last fall.

No. 3. Complete guano.

No. 4. Complete guano.

No. 5. Alabama phosphate rock.

No. 6. Phosphate containing a large percentage of citrate-soluble phosphoric acid.

(To be continued.)

Table of Results.

	1.	2.	3.	4.	5.	6.
Total phosphoric acid—	15·15	16·72	11·90	13·06	28·16	19·77

(To be continued).

Brooke, Simpson, and Spiller, Limited.—The firm of Brooke, Simpson, and Spiller, well known doubtless to most of our readers as having been for many years the largest manufacturers of alkaline colours in the United Kingdom, has been converted into a limited liability company. The share capital is £150,000 in 30,000 shares of £5 each. The former partners in the firm will join the Board of the new Company, and Mr. A. Brooke will act as managing director. As a proof that in spite of the imperfection of our patent laws coal-tar colours may be successfully manufactured in Britain we may mention that, according to the accountant's report, the profits made by the late firm from 1877 to the end of 1885 would have allowed of an annual dividend of 12 per cent upon the total share capital.

NOTICES OF BOOKS.

The Chemistry of the Coal-Tar Colours (Technological Handbooks). Translated from the German by Dr. R. BENEDIKT, and Edited, with Additions, by E. KNECHT, Ph.D., Head Master of the Dyeing Department of the Technical College, Bradford, Editor of the *Journal of the Society of Dyers and Colourists*. London: G. Bell and Sons.

WE have here a most valuable addition to English technical literature. We have no recent work which gives a comprehensive survey of this rich and apparently inexhaustible department of industrial chemistry.

The book opens with a brief historical account of the principal discoveries and inventions in this field, which may be said to have originated with the detection by Garden, in 1820, of naphthalene as a constituent in coal-tar.

In the first chapter the author treats of the optical properties of colouring-matters, the decomposition of light by the prism, the absorption-spectra of organic colouring-matters, fluorescence, and on the spectroscope as a means of detecting colouring-matters. There is here sound instruction on a subject too much neglected by many dyers and colourists. The views here laid down on primary colours are peculiar. Newton and his disciples, including one of the most eminent authorities on colours, Prof. Chevreul, recognise three primary colours, red, yellow, and blue; Young and Fresnel, with their numerous and distinguished followers, regard as primary colours red, green, and violet; and Dr. Benedikt differs from both parties by adopting four primary colours, red, yellow, green, and blue. Spectrum analysis the author considers as "only of minor importance to the colour chemist." We next find an account of the general chemical properties of the colouring-matters; an account of chromophorous and salt-forming groups; a classification of artificial colouring-matters according as they are basic, acid (including the sulphones), or neutral.

The methods of dissolving the colours are next taken into consideration—a process in which a few years ago, if not at present, grave errors were often committed. Dr. Benedikt very rightly recommends that methylated spirits used should be free from impurities, especially aldehyd and acetone, which act very injuriously on certain dyes. But to follow this good advice is not very easy in England, since the Inland Revenue does not allow methylated spirit, or even mere wood-spirit (methylic alcohol), to be sold duty free if the purification has been carried beyond a certain degree. Hence colours soluble in other media are preferable for use in this country.

In proceeding to dyeing, properly speaking, Dr. Benedikt gives an account of the chemical properties of the three principal fibres, silk, wool, and cotton, and considers the relations of these fibres to colouring-matters, substantive dyeing, adjective dyeing with mordants, the metallic hydrates, sulphur, metallic sulphides, silica, double cyanides, the oil mordants, soaps, tannin mordants, albuminous and gelatinous substances, fast and loose colours, testing colouring-matters, comparative dye-trials, colorimetry, and impurities in colouring-matters.

Part II. is devoted to coal-tar and to such of its constituents as have been found eminently useful in colour-making, *i. e.*, benzene, toluene, the xylenes, naphthalene, anthracene, and phenol.

In Part III. we find a classification of the coal-tar colours into the anilines, the phenols, the azos, and the anthracenes, each of them subdivided into several groups. The various colours are then made the subject of special treatment, including the composition, the constitution, and the synonyms of each, its uses, and the principles of its preparation.

This work will be valuable not merely to dyers, printers, colour-manufacturers, and technical students, but, in virtue of its great clearness, we can recommend it to all young chemists who are grappling with the organic department of the science. All such will find its thorough study an excellent discipline, even if they have no intention of concerning themselves with any branch of the tinctorial art.

CORRESPONDENCE.

ESTIMATION OF MAGNESIUM.

To the Editor of the Chemical News.

SIR.—Allow me to add my testimony to the value of a modification in the method of precipitating ammonium magnesium phosphate described in your issue of Feb. 26, 1886, by Mr. Lawrence Briant, F.C.S., (CHEM. NEWS, vol. liii., p. 99). This modification has been in use in my laboratory since 1880. The experimental tests were executed for me by my late pupil, Mr. W. P. Gibbs, now chemist to Messrs. Newton, Keates, and Co., St. Helens, and I communicated the idea to Dr. Voelcker in a private letter some time about May, 1881.—I am, &c.,

W. F. K. STOCK.

Darlington, March 10, 1886.

CHEMICAL NOTICES FROM FOREIGN SOURCES.

NOTE.—All degrees of temperature are Centigrade unless otherwise expressed.

Comptes Rendus Hebdomadaires des Séances, de l'Académie des Sciences. Vol. cii., No. 2, March 1, 1886.

On the Spectra of Erbia.—W. Crookes.—For the contents of this paper see CHEMICAL NEWS, vol. liii., p. 75.

Crystallisation of Sodium and Ammonium Paratartrate.—J. Joubert.—With reference to M. Bichat's communication in the *Comptes Rendus* for Feb. 22 last, the author describes the method which he used about ten years ago for the same purposes in M. Pasteur's laboratory. This method consists in passing, with all the precautions necessary for keeping out atmospheric dust, a continuous current of dry air over the surface of the solution of the salt. In this manner are obtained fine crystals of paratartrate without hemihedric facets.

Isomeric States of Chromium Sesquichloride (Green Sesquichloride).—A. Recoura.—The author applies thermo-chemical methods to the study of the isomeric states of this chloride. He concludes that the totality of his experiments forms a cycle in which by setting out from the green solution we arrive at a violet solution. The violet solution is a definite state.

Certain Proximate Principles of the Bark of Bitter Orange.—M. Tanret.—The author isolates and distinguishes a weak acid, $C_{44}H_{28}O_{14}$; a non-crystalline body excessively bitter, and which does not yield glucose on treatment with acids; a glucoside, isohesperidine; a bitter principle, aurantiamarine, which is a glucoside, and hesperidine in the form of a white powder.

Berichte der Deutschen Chemischen Gesellschaft zu Berlin Vol. xix., No. 1.

Action of Acetyl Chloride upon Pyridine.—M. Dennstedt and J. Zimmermann.—The authors have not succeeded in obtaining dehydracetic acid from acetyl-chloride, either by passing its vapours at different tempera-

tures through glass or iron tubes, or by heating it alone in a closed tube, or by heating with lead oxide.

On Conessine.—K. Polstorff and P. Schirmer.—Conessine, $C_{12}H_{20}N$, crystallises in tender silky needles. When dried it forms a loose mass, of a dazzling whiteness, fusible at 121·5. It is sparingly soluble in water, but very readily in alcohol, ether, chloroform, and benzol. The most dilute solution of its hydrochlorate gives a red-brown precipitate with an iodised solution of potassium iodide.

On Acid Diphenylether and some of its Derivations.—A. Rössing.—Not adapted for useful abstraction.

Do the Statical and Dynamical Methods of Determining Vapour Tension give Different Results? A Reply to G. W. A. Kahlbaum's Answer.—W. Ramsay and S. Young.—This paper would require to be accompanied by the accompanying tables and diagram.

Journal für Praktische Chemie.
New Series, Vol. xxxiii., Part 1 and 2.

Researches on Isatoic Acid and its Derivatives.—This investigation includes a number of memoirs describing reserches executed in the laboratory of the editor, Prof. E. von Meyer, with his co-operation or under his supervision. Isatoic acid, discovered by the late Prof. H. Kolbe, is identical with anthranil carbonic acid. The following are the memoirs in question:—

I. **On Isatoic Acid.**—E. von Meyer and Th. Bellmann.—This paper describes the behaviour of isatoic acid with benzoylchloride, hydroxylamin, phenylhydrazin, formic hydrate, phosphorus pentachloride, and calcium hypochlorite; the identity of isatoic acid and anthranilcarbonic acid is demonstrated. Acetylisatin is shown to be a compound not analogous to isatin in its constitution.

II. **On the Haloid Derivatives of Isatoic Acid.**—R. Dorsch.—The author has examined the behaviour of bromine with isatoic acid; the behaviour of monobrom-isatoic acid with hydrochloric acid and ammonia; the action of bromine upon nitro-isatoic acid; the action of chlorine upon isatoic acid; the oxidation of the haloid derivatives of isatin to the corresponding ones of isatoic acid; and in particular the oxidation of monobrom-isatin to monobrom-isatoic acid; the oxidation of dibrom-isatin to dibrom-isatoic acid; the behaviour of the latter with hydrochloric acid and ammonia; the oxidation of monochlor-isatin and dichlor-isatin respectively to mono- and dichlor-isatoic acids; and the behaviour of these with hydrochloric acid and ammonia, and an account of nitrobrom-isatin. Lastly, the author discusses the function of the halogens in the above-named compounds.

III. **On Paramethyl-isatoic Acid and certain Derivatives of Paramethyl-isatin.**—W. Panaotovic.—From the experiments here described it appears that paramethyl-isatin is quite analogous in its chemical behaviour to isatin. Hence paramethyl-isatoic acid must be regarded as paramethyl-anthranil-carbonic acid.

Part 3.

Sulphuretted Substitution-Derivatives of Butyric, Isobutyric, and Isovalerianic Acids.—J. M. Löven.—Just as the sulphides of the alcohol radicals can be oxidised to sulphones, sulpho-substituted fatty acids (sulphide-dicarbonic acids) can be transformed into sulphuryl-substituted (sulphon-dicarbonic) acids. In the ethers of these sulphone-acids each two atoms of hydrogen can be replaced. The acids thus arising by the introduction of alcohol-radicals are constituted symmetrically and are identical with the compounds formed by oxidation from sulpho-substituted fatty acids.

On Cyanuric, Di-, and Tri-thiocyanuric Acids.—Peter Klason.—Trithionic acid falls from very dilute solutions in short microscopic prisms of a faint yellowish colour. If precipitated from concentrated solutions it is amorphous and almost white. If boiled with water traces of it pass into sulpho-cyanogen. The author describes the potassium, barium, strontium, and calcium salts of this acid. Dithiocyanuric acid is distinguished from the tri-acid by the circumstance that in it an atom of oxygen is substituted for an atom of sulphur. Whilst trithionic acid belongs to the hydrosulphates, cyanuric acid must be regarded as an oxy-compound.

Cerium Oxide, Yttria, Glucina, and Ammonium Chloride in Diluvial Clays.—Dr. J. R. Strohecker.—(See p. 136).

Contributions to the Chemistry of Sea-Water.—Axel. Hamberg.—An examination of the relations between the sulphates and the chlorides in sea-water.

On Tetra-chlor-thio-pentetrachloride.—C. Willgerodt.—This compound melts without decomposition at 215°, and congeals at a few degrees lower. At 100° it becomes soft and pastey. It has a sharp, penetrating, but not unpleasant, odour. It dissolves freely in chloroform, ether, benzol, carbon disulphate, glacial acetic acid, and alcohol, and appears to sublime undecomposed.

The Preparation of Mono-nitro-anisoles, and Mono-nitro-phenetoles according to Kolbe's Method.—C. Willgerodt and M. Ferko.—The authors have succeeded in obtaining paranitro-anisol and paranitro-phenetol by this method in extraordinary purity. The melting-point of the former is not 51°, but 54°, and that of paranitrol-phenetol not 57° to 58°, but 60°. The corresponding ortho-compounds were obtained in the form of oils.

On certain Aromatic Iodide-Chlorides.—C. Willgerodt.—An account of phenyl-iodide-chloride, para-brom-phenyl-iodide-chloride, symmetric α-tribrom-phenyl-iodide-chloride, and paranitro-phenyl-iodide-chloride.

Part 4.

Communications from the Chemical Laboratory of the University of Leipzig.—E. von Meyer.—This consists of a memoir by M. Striegler on melanurenic acid. The principal results are that melanurenic acid forms well characterised salts both with acids and alkalies, the former of which are of little permanence. The acid character is therefore more decided than the basic properties of melanurenic acid. It is bibasic, and has probably the composition $C_6H_8N_8O_4$. With phosphorus pentachloride it forms phosphorus oxychloride and cyanuric chloride. With other reagents it is indifferent.

Contributions to the Knowledge of the Aromatic Ketones.—Karl Elbs.—In this memoir the author studies the processes for preparing the homologues of benzophenon, the reduction of aromatic ketones to secondary alcohols, the preparation of the β-pinacolines, and the synthesis of anthracenes from from aromatic ketones by splitting off water.

On certain Derivatives of Sulphurea.—G. McGowan.—The author has examined the behaviour of disulphurea dichloride with dilute nitric acid, the action of iodine chlorides upon sulphurea, and the action of potassium iodide upon disulphurea dichloride.

Researches from the Chemical Laboratory of Prof. Saytzeff at Kasan.—These consist of a paper by A. Tschebotareff and Al Saytzeff, on the reaction of ethyl-iodide upon zinc and butyrone, and the synthesis of ethyl-dipropyl carbinol; and a memoir by Gortaloff and Al. Saytzeff, on the reaction of methyl iodide and zinc upon butyrone, with the synthesis of methyl-dipropyl carbinol.

On New Compounds of Rhodium.—C. Vincent.—From the *Comptes Rendus*.

Journal de Pharmacie et de Chemie.
Series 6, Vol. xiii., No. 3, February 1, 1886.

Analysis of the Juices of Mulberries.—E. Falières.—This analysis refers not to the fruit but to commercial juices and syrups.

Study on Milk in the Paris Hospitals and on an Apparatus for its Preservation.—Dr. Adam.—The author denies the constancy of the composition of milk, which few, if any, authorities have asserted. The preservative apparatus cannot be described intelligibly without the accompanying figures.

Microscopic Search for Foreign Pulps in Preserved Tomatoes.—P. Famel.—This paper requires the accompanying illustrations.

Seven Cases of Poisoning by Preserved Tomatoes.—F. Doggett.—Three of these cases are due to stannous chloride and four to a salt of lead.

Researches on the Dangers of the Aniline Colours.—L. Poincarré.—The author gives a table showing the mean time in which doses of aniline colours (and of the crude materials from which they are derived) required to prove fatal:—Binitrobenzol, one day; picric acid, violet (?), dimethylaniline, safranine, four days; binitrotoluol and orthotoluidine, five days; magenta, chrysoidine, paratoluidine, and green (?), seven days; resorcine, eight days; toluol, nine days; naphthylamine, ten days; naphthol, diphenylamine, acetanilide, eleven days; phthalic acid, thirteen; and Hofmann's violet, twenty-two days. The mean dose which had been taken up to the time of death was:—Phthalic acid, diphenylamine, paratoluidine, and acetanilide, 1 grm.; naphthylamine and resorcine, 0·8; chrysoidine, 0·7; magenta and "green," 0·6; binitrotoluol, 0·4; violet, 0·3; Hofmann's violet, binitrobenzol, safranine, toluidine, orthotoluidine, and picric acid, 0·1 grm. The author remarks that the products used were free from mercury, &c. (It must be noted that he does not state what proportion the fatal dose bears to the living weight of the animal, and that his results do not agree well with those of other observers.)

Microscopic Organisms in the Air of the Sea.—MM. Moreau and Miquel.—The air of the sea taken at a great distance from land, or even on the shore and in ports when the wind blows from the open, is in an almost perfect state of purity. Near continents the land-winds drive before them an atmosphere always impure, but at 100 kilometres from the coasts this impurity has disappeared. The sea rapidly purifies the pestilential atmosphere of continents; hence every expanse of water of a certain breadth becomes an absolute obstacle to the propagation of epidemics. Marine atmospheres driven upon land purify sensibly the air of the regions which they traverse; this purification can be recognised as far as Paris.

The sea is the tomb of moulds and of aërial schizophytes.

MEETINGS FOR THE WEEK.

MONDAY, 22nd.—Medical, 8.30.
—— Society of Arts, 8. (Cantor Lectures). "Petroleum and its Products," by Boverton Redwood, F.C.S.
TUESDAY, 23rd.—Institution of Civil Engineers, 8
—— Royal Institution, 3. "The Function of Circulation," by Prof. Arthur Gamgee, F.R.S.
—— Royal Medical and Chirurgical, 8.30.
—— Society of Arts, 8. "Canada and its National Highway," by Alexander Begg.
WEDNESDAY, 24th.—Geological, 8.
—— Society of Arts, 8. "Domestic Electric Lighting," by W. H. Preece, F.R.S.
THURSDAY, 25th.—Royal, 4.30.
—— Royal Institution, 3. "Electro-Chemistry," by Prof. Dewar, F.R.S.
—— Royal Society Club, 6.30.
—— Society of Arts, 8. "Certain Appliances for the Utilisation of Refuse and Dust Fuels," by Walter G. McMillan.
FRIDAY, 26th.—Quekett Club, 8.
—— Royal Institution, 9. "On Certain Properties common to Fluids and Solid Metals," by Prof. W. Chandler Roberts-Austen, F.R.S.
SATURDAY, 20th.—Royal Institution, 3. "The Astronomical Telescope," by Howard Grubb, F.R.S.
—— Physical, 3. "On an Arc Lamp suitable for the Duboscq Lantern," by Prof. S. P. Thompson.

UNIVERSITY OF MELBOURNE.

CHAIR OF CHEMISTRY.

The Chair of Chemistry in the University of Melbourne being now VACANT, candidates for appointment are requested to send in their written applications, which should contain the names and addresses of their references, or be accompanied by copies of testimonials in triplicate, on or before the 29th instant, addressed to the undersigned. The duties of the Professor will be to teach—(1) Inorganic Chemistry; (2) Organic Chemistry; (3) Metallurgy; (4) Practical Chemistry, with general supervision of the laboratory practice by the students, and generally to perform the customary duties of a professor. The Professor will have the aid of a competent assistant.

The salary will be during the first five years £750 a year with a house, or £100 a year in lieu of a house; at the end of each successive fifth year the professor (if his work be approved by the Council) will be entitled to an additional sum of £150 until his salary amounts to £1200 a year and a house, or house allowance as aforesaid, when it will not be further increased. He will hold his office "quamdiu se bene gesserit."

(Signed) R. MURRAY SMITH.
Agent-General for Victoria.

Victoria Office, 8, Victoria Chambers, Westminster.

FOOD AND DRUGS ACT.

The County of Hants will at the next Easter Sessions appoint a PUBLIC ANALYST for the County for a term of three years.—Analysts desirous of applying for the office must send in their applications stating qualifications, terms as to remuneration, &c., to the Clerk of the Peace, County Hall, Winchester, on or before the 31st inst. The Analyst will only be required to analyse at his private laboratory, to which all samples will be sent free of charge. Payment per analysis. Number of samples not guaranteed.

CHEMICAL MANURE AND SULPHURIC ACID WORKS.

TO BE SOLD by Public Roup, within Dowell's Rooms, 18, George Street, Edinburgh, on Wednesday, 24th March, 1886, at 3 o'clock p.m. (unless previously sold by private bargain).

Chemical Manure and Sulphuric Acid Works, presently carried on by Hume Brothers and Company, Limited, at Bo'ness, Linlithgowshire, these extensive Works, which are in good going order, are well situated, and adapted for carrying on Manure Manufacturing. They lie close by the New Dock at Bo'ness and are connected therewith by railway sidings which run through the Works. Vessels of over 2000 tons burthen can be discharged in the Bo'ness Dock, which is fitted with the newest hydraulic machinery. A large sum has been spent on the fixed Plant at the Works, the greater part of which has been erected within the past three years, and the Mills, Engines, and other Machinery are all of the best description and in first-class order. The Furnaces, Acid Towers, and Acid Chambers are likewise in good order.

A comfortable Dwelling-house for Works-foreman, Laboratory Workshops, and convenient Offices are within the ground.

The whole ground, which extends to about 2 acres, 1 rood, 36 poles, 24 yards, is held upon a long lease, 86 years of which have yet to run. The ground rent is £39 13s. 7d. per annum.

For further particulars apply to Mr. James McGown, Manager, at Bo'ness; or, to Davidson and Syme, W.S., 22, Castle Street Edinburgh, who have the title deeds and articles of roup.

Analytical Laboratory to Let.—Two rooms with benches, gas-supply &c. Balances and library optional. Immediate possession if required. Rent, £30 per annum.—34, Old Broad Street, E.C. Apply to F. R. Johnson.

Chemical Works, established 39 years (in Midlands), making Vitriol, Oxide Iron, Ammonia, Manure, &c., for Sale by Private Contract (principals only).—Address, E.B., care of Mr. W. J. Gallop, Railway Station, Derby.

FOR SALE.

Sulphuric Acid Works, facing the Thames. Capable of producing 35 to 40 tons per week.—Apply, W. W., CHEMICAL NEWS Office, Boy Court, Ludgate Hill, London, E.C.

FOR SALE.

COMPLETE SET (unbound and uncut) of

THE CHEMICAL GAZETTE,

A Journal of Practical Chemistry.

17 Volumes; from November, 1842, to December, 1859.

Address, "Publisher," CHEMICAL NEWS Office, Boy Court, Ludgate Hill, London, E.C.

THE CHEMICAL NEWS.

Vol. LIII. No. 1374.

ON THE DECOMPOSITION OF POTASSIC CHLORATE BY HEAT.

By E. J. MAUMENÉ.

The Chemical Society, at its meeting on the 5th of November last, received a paper by Mr. Frank L. Teed on the Decomposition of Potassic Chlorate by Heat.

Having been myself occupied with this subject at several different times, I hope that the Society will be good enough to accept some observations which seem to me to be of the highest importance.

My first experiments on this subject go back as far as the years 1845 and 1846. They were published in the *Annales de Chimie et de Physique*, vol. xviii., p. 41 (3rd series).

With the object of finding out very accurately the weight of the residue left by the complete decomposition of the chlorate, I concentrated all my care in establishing two points:—

1st. To maintain the temperature at a sufficiently high point to keep the potassic chloride in complete fusion; I obtained this result in the following manner:—I placed bits of charcoal (gas was not then in use) of a uniform size, that of the little finger, in a very regular manner round the very hard glass retort which I was using. During the whole of the operation I prevented the contact of the charcoal and the glass, and I succeeded a great number of times in obtaining the chloride entirely liquid and perfectly transparent even after solidification. I place at the disposition of the Society some of the retorts which I used.

2nd. To determine if the weight of the glass would remain invariable in spite of my extreme precaution.

As the weight of the residue of chloride should be estimated by difference, it was necessary to be able to depend on the invariability of the glass to less than half a milligramme, a degree of accuracy quite possible in such experiments.

The variability of the glass seemed to me, *à priori*, to be a considerable source of error. The glass, even without touching the charcoal, or rather its ash, is exposed to a red-heat for two or three hours in a current of air and ash in a state of atomic powder, the presence of which is shown by even a rough experiment, such as heating a copper pot of water: this pot, though very bright at first, becomes covered before long with a white deposit, soluble in water, and composed almost entirely of sodic and a little potassic chlorides.

The retorts in which the chlorate is decomposed receive the same substances mixed with watery vapour; they absorb while decomposing, according to a well-known reaction, the principal part, viz., the sodic chloride—

$$SiO_2 + NaCl + HO = SiO_2.NaO + HCl.$$

This action is produced without altering the polish of the glass to an appreciable extent, and increasing the weight of the retorts, in the following manner:—

Tare of the Retorts.

Before.	After.	Increase of weight.
29·810	29·848	0·038
21·108	21·153	0·045
29·812	29·848	0·036
48·069	48·100	0·031
48·138	48·189	0·051
30·1865	30·2285	0·142
36·113	36·152	0·039

The Society sees of what interest this very simple observation was at a time when glass was considered unchangeable under the conditions indicated.

The complete work obtained for me a public recognition from Berzelius, of which I would not speak if it were not necessary to offer to the Chemical Society a guarantee of the value of my experiment (*Compte Rendu Annuel*, 1848, p. 12).

Since this period I have made a fresh study of the subject from another point of view, that of the change to heptachlorate.*

This point of view was forced on me by the general theory of chemical action of which the first conception was presented to the Académie des Sciences on March 6th, 1864, and which, in spite of its advantages, is very little known.

One of the proofs of the correctness of this theory seems to me to be the explanation of the fact, *inexplicable without it*, of the production of the heptachlorate by the decomposition of potassic chlorate.

Below is the proof, as it was published in the *Mondes* of June 13th, 1872, p. 262 (after a short preamble which is necessary to understand the calculation of the decomposition, and which I reproduce):—

Preamble.—All compound bodies submitted to the action of heat ought to be considered at the moment of their decomposition simply as mixtures of the two bodies of which they are formed; for example, a salt formed of an acid and a base is nothing more than a mixture of this acid and this base at the moment when heat brings about the decomposition of this salt. We can calculate, *à priori*, the results of the decomposition by applying the law of mixtures; the following are examples:—

3rd. *Decomposition of Potassic Chlorate.*—Before going any further I must beg the Society to allow me to make a slight deviation. It is now nearly twenty-two years since my "Theory" was published: during this long time I have never ceased accumulating information on analogous examples. I am able to state that I have never up to the present time found *any exception* to the rule which I have just mentioned. *Chemistry in its entirety can be calculated by means of the two laws of the "General Theory."*

We have for the two constituent bodies $ClO_5 = 75{\cdot}5$, $KO = 47$,—

$$\overline{|M|}\, n = \frac{75{\cdot}5}{47}.$$

Strictly speaking the calculation ought to be done with these two numbers, and I ought to write—

$$47ClO_5 + 75{\cdot}5KO = \ldots;$$

but this calculation is sometimes very fatiguing, and, while insisting on the necessity of doing it when very great accuracy is needed, I have simplified the numbers as follows:†—

$$n = \frac{75{\cdot}5}{47} = 1{\cdot}61, \text{ say } \frac{16}{10} = \frac{8}{5}.$$

$$8KO + 5ClO_5 = 2ClO_7,KO + 3KO_4 + 3ClK + 5O \ldots (\delta)$$

There remains $3ClO_5$ *free*.

This consequence of the Theory, this *free* $3ClO_5$, has perhaps influenced the minds of chemists more than anything else in making them reject the Theory itself without further examination.

But what can be more simple? that the two constituents of the salt, ClO_5 and KO, should be entirely separated, and therefore *free*, at the moment of decomposition, is undeniable. That these two bodies, free at a certain temperature, should form other bodies, *stable at the same*

* It would be preferable to call it *chlorogale*, according to the rule which I proposed—"Théorie Générale de l'Action Chimique," 1880, p. 493.

† Mistakes which I was unable to prevent in the *Mondes* oblige me to continue with that which was printed in my "Théorie Générale," p. 110 to 115.

temperature, is also undeniable and easy of comprehension.

The only point which is not so easy to understand is that the two bodies react at equal weights.

But the Chemical Society may find in my General Theory (of which I have the honour of bringing forward an example) a sufficient number of proofs of the accuracy of the calculations based on this fact to grant me its indulgence when I say *these calculations are never wrong.*

Since at equal weights 8KO can only react with $5ClO_5$, the three other molecules of ClO_5 in the retort are free at the moment of decomposition: *they are during a time more or less limited, but always very short,—nothing more than witnesses of the action of the five first molecules with the* 8KO.

Should this fact prevent them from reacting, *a little later*, with the products of the first reaction (which I call the normal reaction)? Evidently not! for example, they react with KO_4, *always following the law of equal weights*, and give ($KO_4=71$):—

$$\boxed{M}\ n = \frac{75{\cdot}5}{71} = 1{\cdot}06, \text{ say } 1{\cdot}00.$$

$$ClO_5 + KO_4 = ClO_7.KO + O \quad \ldots \quad (\gamma)$$

and since we have $3ClO_5$ at the same time as $3KO_4$, we get—

$$3ClO_5 + 3KO_4 = 3ClO_7.KO + 3O \quad \ldots \quad (\gamma)\times 3.$$

No other reaction is possible at this temperature.

Now if we wish to represent the first phase of the decomposition of the chlorate, that which produces the heptachlorate with any destruction of the salt (*the maximum production*), we can do it by simply adding the two equations (δ) and (γ)×3, as follows:—

$$\begin{array}{rrrrr} 8KO + 5ClO_5 & = 2ClO_7.KO & + 3KO_4 + 3ClK & + 5O & (\delta) \\ 3KO_4 + \quad 3ClO_5 & = 3ClO_7.KO & & + 3O & (\gamma)\times 3 \\ \hline 8KO \;.\; ClO_5 & = 5ClO_7.KO & & + 3ClK + 8O & (m). \end{array}$$

I have given sufficient proof of the soundness of this calculation by the direct extraction of ClO_7KO, obtained at a constant temperature in a bath of fusible metal or of solder.

The working out of the equation (*m*) leads us to—

1. Maximum production of heptachlorate.. 70·66
2. Oxygen given off .. .. 6·53

With the greatest care I have not been able to extract more than 68·20 of heptachlorate instead of 70·66; but I must not forget to state that the *simplified* calculation which I have just brought forward gives a figure a little too high, as we shall see directly.

As to the oxygen liberated, not having yet spoken of it I will say nothing now, but will revert to it later on.

I now come to the work of Mr. Teed.

Our colleague has evidently set himself to estimate the two products of which the value can be found with great accuracy.

1st. *Oxygen set free.*—This gas can be estimated by the difference in weight of the retort before and after heating. We need not fear that the glass has changed in weight, as carbon was not used; Mr. Teed used a small lamp (whether gas or oil it matters not).

2nd. *Chloride of Potassium produced.*—This body can be weighed with the greatest accuracy by dissolving in water, as Mr. Teed did, the residue of the decomposition, either partial or complete, of the chlorate, and estimating the chloride by means of a decinormal solution of nitrate of silver (with a chromate as indicator).

By this means Mr. Teed has studied the more or less advanced decompositions of the chlorate, and by comparing the results he has made use of the following terms in the equation for the maximum production of heptachlorate:—

$$10ClO_5.KO = 6ClO_7.KO + 4KCl + 12O \quad \ldots \quad (T).$$

Now the Chemical Society can at once see that the equation is in fact nothing more or less than the one I gave *thirteen years ago.* In fact if we multiply the equation (*m*) by $\frac{4}{3}$ it becomes—

$$10ClO_5.KO = 6{\cdot}25ClO_7.KO + 3{\cdot}75KCl + 10{\cdot}728O \ldots (m)\times\tfrac{4}{3}.$$

No one, I venture to say, can help understanding, even at the first glance, the reasons of the slight differences between the two equations of Teed and Maumené.

These differences come from two causes:—

The first is that Mr. Teed, still imbued with the classical hypothesis,—that is to say, having faith in the most simple coefficients,—has simply written—

6·0000 ClO_7 KO and
4·0000 ClK

without being able to guarantee the absence of all decimals.

The second cause is that M. Maumené, in spite of his recommendation to calculate, *in important cases*, with non-simplified numbers, has given the results simplified *arithmetically*, but slightly incorrect *chemically*, in order to diminish the shock of novelty of his theory.

The true numbers would be—

$$\begin{array}{rrrr} 75{\cdot}5KO + 47ClO_5 & = 18ClO_7.KO + 28{\cdot}5KO_4 + 29KCl + & & \\ & & +52{\cdot}5O & \ldots (\delta') \\ 28{\cdot}5KO_4 + 28{\cdot}5 & = 28{\cdot}5ClO_7.KO & + & \\ & & +28{\cdot}5O & \ldots (\gamma') \\ \hline 75{\cdot}5ClO_5.KO & = 46{\cdot}5ClO_7.KO & +29KCl + & \\ & & +81O & \ldots (m') \end{array}$$

or, dividing by 7·55,—

$$10ClO_5.KO = 6{\cdot}159ClO_7KO + 3{\cdot}841ClK + 10{\cdot}728O,$$

an equation of which the differences with that of Mr. Teed are sufficiently slight to really leave no doubt in the minds of competent people.

1st. Mr. Teed's equation is an approximation very near the truth, but an approximation.

2nd. M. Maumené's equation, dictated by a general theory, is an approximation still nearer the truth, as is proved more and more, as very exact experiments are made, like those of Mr. Teed.

Mr. Teed has observed, as I myself have already done, that the classic equation—

$$2ClO_5.KO = ClO_7.KO + KCl + 4O$$

has no justification. I should be permitted to repeat what I have so often said (*vox clamans in deserto*, or nearly so), —*No classic equation is correct.*

I must here call the attention of the Chemical Society to the method of calculating the second of my equations, viz., (δ').

Many persons would not willingly admit the possibility of $28{\cdot}5KO_4$ by the side of 29KCl: a body very rich in oxygen next to a body which had none, one would be tempted to say—

$$12KO.ClO_7 + 28{\cdot}5KO + 17KCl,$$

but it would be necessary, in order to divide the oxygen in this manner, for KO to be a body which has lost all tendency to peroxidation; and it is not for English chemists to learn the results of Mr. Vernon Harcourt's work (nor even the earlier works of Gay-Lussac and Thenard).

It is therefore necessary to divide the oxygen in such a manner as to form the greatest possible quantity of KO_4, because the existence of this body is not only possible at the temperature of the decomposition of the chlorate, but it is even more stable than the heptachlorate. And now, if the Society will continue to bestow on me this attention, which it may rest assured I will not abuse, I hope to have the honour of bringing before it a fact of the highest importance.

I have used KO_4 in my calculations because the *shock of novelty* of the theory, of which I have just spoken, forces me to use the results of experience, such as KO_4 without any alteration. But any chemist who asks him-

self why the alkaline peroxides are KO_4 for potassium, NaO_2 for sodium, &c., will certainly find no answer in classical chemistry armed with all its resources.

The Chemical Society will certainly not refuse to allow that the General Theory undertakes to reply to such questions, and makes the following answers:—The peroxide of potassium is not KO_4, but KO_5, or more exactly K_8O_{39}, because it is formed at equal weights. The peroxide of sodium is not NaO_2, but NaO_3, or more exactly Na_8O_{23}, because it also is formed at equal weights.

The researches made on these bodies before this theory gave KO_4 according to Vernon Harcourt,

NaO_2 „ „

NaO_3 „ Gay-Lussac and Thenard.

The General Theory leaves me no sort of doubt as to these indications, above all in such simple cases; I have commenced a series of experiments, of which the first results are very nearly K_8O_{39} and Na_8O_{23}. I shall publish them soon. But in the meantime, and in the conviction of having to admit these numbers, I have made the calculation of the decomposition of the chlorate with KO_5 (for simplicity) instead of KO_4. This modification will not sensibly affect the results, and not to fatigue the Society I will not insist on it.

I only ask permission, in closing, to commend to the Society the General Theory, the truth of which becomes more evident every day as the tests to which it is submitted are made with greater accuracy.

Mr. Teed was certainly not guided by it, and still he has just confirmed its indications by a new and perfectly independent proof.

THE DIASTATIC ACTION OF SALIVA, AS MODIFIED BY VARIOUS CONDITIONS, STUDIED QUANTITATIVELY.*

By R. H. CHITTENDEN and HERBERT E. SMITH.

(Continued from p. 138.)

Influence of Free Acid and of Acid-Proteid Matter on the Diastatic Action of Saliva.

THE influence of dilute acid solutions on the diastatic action of saliva is naturally a point of considerable physiological importance. In view of the rapid passage of the salivary secretions into the stomach, we need to have accurate knowledge of the exact influence of free acid and acid-reacting fluids on the ferment and its diastatic activity.

In considering this question we do not need now to take into account the older observations of Jacubowitsch, Lehmann, Schiff, Watson, Brücke, Hammarsten, and others, since these led to no agreement of opinion, and more recently acquired knowledge has rendered necessary different methods of procedure.

In 1881 it was announced by one of us† that the ferment of saliva was destroyed on being warmed for two hours with gastric juice containing 0·2 per cent hydrochloric acid; also that the same treatment with 0·2 per cent hydrochloric acid alone caused great destruction of the ferment, so that on neutralisation diastatic action was greatly diminished. At the same time it was pointed out that much smaller percentages of acid, even 0·025 per cent,‡ diminished the diastatic action of the ferment very materially. Shortly after this similar results were obtained independently by Langley,§ who, in an interesting paper on the destruction of ferments in the alimentary canal, pointed out that ptyalin from the parotids of a rabbit was destroyed by digestion with a small amount of gastric juice, and also that weak solutions of the ferment were more or less destroyed by heating at 40° C. with 0·014 per cent hydrochloric acid. In comparing these latter experiments with the preceding, it is to be remembered that the former were made with 25 c.c. of filtered human saliva,—a much stronger solution doubtless, both as regards the ferment and the albuminous matter present.

Later it was pointed out by one of us* that peptones have a very decided influence on the diastatic action of saliva in acid solutions; that while the presence of 0·025 per cent hydrochloric acid prevented the conversion of but 3·50 per cent of the starch into sugar, the presence of 1 per cent peptone allowed the conversion of 48·85 per cent of the starch, 7 per cent more than the saliva alone would convert under like conditions,—a fact which would indicate something more, on the part of the proteid matter, than a mere union of the peptone and acid. Undoubtedly there was a combination of the peptone and acid, but in addition there was manifested the direct stimulating action of the proteid matter. At the time these experiments were made, however, we were unaware of Danilewski's† method of testing for free acid with tropæolin oo, by which he proved the union of acids with various forms of proteid matter; compounds acid to test-papers, but not containing free acid. Falk‡ likewise noticed the influence of peptones on diastatic action, in an acid solution of malt infusion; thus by adding a small amount of 0·0135 per cent hydrochloric acid to an infusion of malt, and this to some starch paste, no reaction for sugar could be obtained; but by adding the same proportion of acid and some peptone, then the sugar reaction soon appeared. This fact Falk considered as evidence of the union of the acid and peptone.

In view of these results we have repeated some of our previous work, under different conditions, trying many additional experiments, especially as in a recent paper on the amylolytic action of saliva, Langley and Eves§ have arrived at some conclusions not in accord with our results.

a. Influence of Acid-Proteid Matter.

We have used the tropæolin test for the detection of free acid, whenever it has been necessary in our work, employing the method as recommended by Danilewsky. The tropæolin oo was dissolved in methyl alcohol (saturated solution), and, when a test for free acid was to be made, drops of the alcoholic solution were allowed to evaporate on a porcelain plate at 40° C., and then, while still at 40° C., a drop of the fluid to be tested was added and allowed to dry. Free hydrochloric acid causes the dry residue to take on a violet colour. We have made a number of trials to ascertain how small a percentage of free hydrochloric acid can be detected by this test. Using a standard solution of hydrochloric acid of known strength,‖ we have found that 0·003 per cent of this acid can be detected with certainty, a drop of such a mixture giving a distinctly recognisable violet colour. A smaller percentage cannot be recognised, and we have therefore invariably deducted the above amount in our various tests for free acid.

The amount of proteid matter naturally present in saliva, and which is capable of combining with acids, is apparently quite constant. Langley and Eves found, as a mean of several observations, that 5 c.c. of filtered neutralised saliva contained proteids capable of combining with 2 c.c. of 0·1 per cent hydrochloric acid. We have found, as a mean of eight determinations, that 20 c.c. of filtered neutralised saliva contained proteids capable of combining with 7·74 c.c. 0·1 per cent hydrochloric acid. In an attempt to ascertain approximately how much

§ *Loc. cit.*
‖ All of our standard acid solutions were of exactly the strength specified, as was proved by titration with standard solution of silver nitrate.

proteid matter this amount of acid signified, we took the results of our experiments with peptones, in which we found that one grm. of pure neutral peptone required 48·0 c.c. 0·1 per cent hydrochloric acid to saturate it. Consequently 1 c.c. of 0·1 per cent acid would combine with 0·0208 grm. peptone, and, assuming that the combining power of the proteids present in saliva is the same as that of peptones, the 20 c.c. of saliva would contain 0·16099 grm. proteid matter, equal to 0·804 per cent,—a result which at once shows that the combining power of the proteids of saliva and peptone must be quite different, or, as is more probable, that considerable of the acid added is used up in reacting with the phosphates of the alkalies present in the saliva.

Saliva, as a rule, does not contain much more than 0·5 per cent solid matter, and Hammerbacher has found in human mixed saliva 0·139 per cent albumen and ptyalin.*

A comparison of the diastatic action of neutral saliva considerably diluted, and similarly diluted saliva in which the proteids present have been saturated with acid, shows at once that acid-proteid matter, even though present in but small quantity, has a distinctly stimulating action on the salivary ferment.

The following experiments will illustrate this point, and also show the extent of the stimulation:—

SERIES XIV.

A. 40 c.c. filtered saliva were neutralised and then diluted to 200 c.c.

B. 40 c.c. of the above diluted saliva required 6·8 c.c. 0·05 per cent HCl to saturate the proteids present = 0·0074 per cent combined HCl.

Two digestions each were made with A and B, using quantities of the above salivas equivalent to 4 and 2 c.c. of the original saliva.

		Wt. Cu in one-eighth.	Total amount sugar formed.
20·0 c.c.	A ..	0·0913 grm.	0·3720 grm.
23·4	B ..	0·0987	0·4016
10·0	A ..	0·0850	0·3472
11·7	B ..	0·0940	0·3832

		Starch converted.
20·0 c.c.	A	33·49 per cent.
23·4	B	36·15
Increase		2·66
10·0 c.c.	A	31·26 per cent.
11·7	B	34·49
Increase		3·23

It is seen that the addition of the acid in this instance causes a very decided increase in the diastatic activity of the saliva. The amount of combined acid present in the 100 c.c. of digestive mixture in the two cases was 0·0017 and 0·0008 per cent respectively, yet the presence of this small amount of combined acid manifestly acts as a stimulant to the diastatic ferment.† Even still smaller percentages of acid-proteid matter have an equally decided action on the salivary ptyalin.

The following series of experiments illustrate this point, and at the same time are confirmatory of the preceding one:—

SERIES XV.

A. 40 c.c. filtered saliva were neutralised and diluted to 200 c.c.

B. 50 c.c. of the above diluted saliva required 4·75 c.c. 0·05 per cent HCl to saturate the proteids. The solution was distinctly acid to litmus-paper, and contained 0·0043 per cent combined HCl.

Four digestions were made with both A and B, using quantities of saliva in each case equivalent to 4, 2, 1, and 0·5 c.c. of the original saliva.

		Wt. Cu in one-eighth.	Total amount sugar formed.
20·0 c.c.	A ..	0·0925 grm.	0·3768 grm.
21·9	B ..	0·0959	0·3912
10·0	A ..	0·0827	0·3368
10·95	B ..	0·0876	0·3576
5·0	A ..	0·0671	0·2744
5·5	B ..	0·0751	0·3064
2·5	A ..	0·0305	0·1296
2·75	B ..	0·0375	0·1568

		Starch converted.
20·0 c.c.	A	33·85 per cent.
21·9	B	35·22
Increase		1·37
10·0 c.c.	A	30·32 per cent.
10·95	B	32·19
Increase		1·87
5·0 c.c.	A	24·69 per cent.
5·5	B	27·58
Increase		2·89
2·5 c.c.	A	11·68 per cent.
2·75	B	14·10
Increase		2·42

Here the same results are to be seen as in the preceding experiment, although the amount of proteid matter is much less. In both series of experiments it is to be noticed that as the percentage of combined acid is diminished, the difference between the diastatic activity of the neutral solution and the corresponding acid solution is increased; at the same time it is to be seen that in the first series of experiments, where the percentage of proteid matter is larger, there is a greater increase in the conversion of starch with the 23·4 c.c. of acid-reacting saliva than with the 21·9 c.c. of the acid-reacting fluid of the second series of experiments, with its smaller percentage of proteid matter.

(To be continued).

ANALYSES OF COMMERCIAL FERTILISERS.*

(Continued from p. 140.)

ON POTASH.

THE Committee on Potash made the following report:—

Methods of Estimating Potash.

The first meeting of Agricultural Chemists, held in Washington July 28, 1880, recommended the following method of estimating potash:—

Solution in water, removal of sulphates, phosphates, and magnesia by barium hydrate, clearing with oxalate or carbonate of ammonia, and precipitating with platinum chloride.

This method has at least the merit of brevity.

At the meeting of the same Association in Cincinnati, August, 1881, no action was taken with reference to potash.

At the Atlanta convention, May, 1884, Dr. MEMMINGER described a method of determining potash, given below:—

* *Jahresbericht für Thierchemie*, 1881, 269.

† Doubtless these percentages of combined acid are too high, since, as before mentioned, some of the acid added probably reacts with the phosphates naturally present in the saliva.

* From the *Proceedings* of the Second Annual Meeting of the Association of Official Agricultural Chemists, at Washington, D.C., September 1, 1885. Edited by Charles W. Dabney, Jun., Ph.D., North Carolina Agricultural Experiment Station, Secretary.

Two to 2·50 grms. of the fertiliser are weighed from a weighing tube into a beaker (capacity about 400 c.c.). In the case of ammoniated fertilisers, the fertiliser is first subjected to carbonisation at a low temperature, when cotton seed or the like is present. To the material is added 5 c.c. of strong hydrochloric acid and then a little water. Heat is applied, and when the mass is at the temperature of 212° F., boiling water is added until the entire bulk will come to about 200 c.c.; to this is added a slight excess of barium chloride, and after a few minutes' boiling a strong ammonia is added until the mass is entirely alkaline. To this is then added first a slight (very slight) amount of milk of lime, then carbonate of ammonia in excess, and then a slight excess of oxalate of ammonia. The entire contents of the beaker are then brought to the boiling point and there kept for two or three minutes. After the mass has had time to precipitate the fluid is decanted, and after two decantations with boiling water (using 200 c.c. each time) the entire mass is thrown on a filter and washed three or four times with boiling water.

The filtrate is now evaporated in a porcelain dish over the direct flame of a Bunsen burner, and after the evaporation is carried to near the crystallising point of the salts present a little strong ammonia is added and then a few c.c. of oxalate of ammonia. The precipitate which now forms is thrown on a filter and the filtrate caught in a large crucible. After a sufficiency of washing the filtrate is evaporated very carefully until perfectly dry, and then the ammonium salts gotten rid of by ignition over a Bunsen burner. The carbonised mass contained in the crucible is moistened with 1 c.c. of very dilute hydrochloric acid (1 c.c. strong HCl to 4 c.c. of H_2O) dissolved in a little boiling water, and filtered into a weighing crucible (porcelain). The mass is washed until there is no reaction with either litmus-paper or silver nitrate, the contents of the crucible carefully evaporated until no more than about 2·5 c.c. remain in the crucible, and to this is added about 10 c.c. of 95 per cent alcohol, and 5 c.c. of standard bichloride of platinum solution. The precipitate then formed of bichloride of platinum and of potassium is allowed to stand over-night, and in the morning, after the crucible has been jarred to make the precipitate fall to the bottom, the supernatant liquid containing an excess of platinum solution is either poured off or else sucked up by means of a very fine pipette. (I have found this better and easier than decantation.) After three or four washings with alcohol (95 per cent), using about 10 c.c. each time, the same process is employed for removing it, allowing time for each subsidence of the precipitate. The crucible is now placed in a steam bath, and the temperature kept at about 230° F., until the weight of the precipitate is constant. Of course the weight of the crucible subtracted from the weight of the crucible plus the precipitate dried at 230° F., gives the weight of the bichloride of platinum and potassium. In the case of kainite salts I employ the same plan of procedure, using, however, in the precipitations much less of ammonia and carbonate of ammonia, and seldom using oxalate. The original 2 or 3 grms., however, which is contained in my final filtrate after ammonium salts are gotten rid of, is, of course, brought to a definite bulk, and then an aliquot portion taken, so that I shall not have to use too great a quantity of bichloride of platinum.

Professor NOYES suggested the following improvements on the above plan:—

I precipitate with platinum chloride in a small weighed beaker, evaporate, take up with alcohol, wash by decantation, pouring off through a small filter, then extract the filter with hot water, washing into the beaker containing the main precipitate, evaporate to dryness, and weigh. During this last evaporation it is advisable to add a drop or two of aqua regia to avoid reduction to metallic platinum.

Professor STUBBS said, speaking of the above method:—
I use for washing potassic platinic chloride alcohol of 95 per cent purity mixed with one-sixth of its bulk of ether.

Dr. WILEY gave his experience in the use of the Gooch crucible in potash determinations:—

Mr. President, I have heard a great deal of discussion to day about estimating potash on a weighed filter. Now, sir, I think the use of paper filters in such estimation is a relic of barbarism. The perforated platinum of crucible, with its blanket of asbestus pulp, is to chemistry what the breech-loader and needle-gun are to war. The day of flint-lock muzzle-loading muskets and of weighed paper filters has passed. The Gooch filter is the great labour-saving machine of chemical industry. In potash determinations the double salt can be first dried and weighed. Then the salt is decomposed by ignition in a stream of hydrogen, the potassium chloride washed out, and the crucible dried and re-weighed. Thus an easy and reliable check is placed on every determination.

At the same Convention the Committee on Potash, consisting of Drs. E. H. JENKINS, W. J. GASCOYNE, and H. W. WILEY, made the following recommendation:—

That for the present nothing better could be suggested for the determination of potash than the plan adopted by the Washington convention.

The report was adopted.

At the Philadelphia meeting, September 1884, the above Committee on Potash reported the following method, which was adopted:—

Boil 10 grms. of the fertiliser with 5 c.c. of strong hydrochloric acid and 300 to 400 c.c. of water for 10 minutes. Cool the solution, and, without filtering, make it up to 1000 c.c.; mix thoroughly and filter through a dry filter.

Take an aliquot corresponding to 0·5 or 1 grm.; dilute, if necessary, to about 150 c.c.; heat to boiling, and precipitate the sulphuric acid with a slight excess of barium chloride solution. Without filtering add an excess of barium hydroxide, and heat again to boiling. Filter and wash, at first by decantation, till the washings are free from chlorides. Heat the filtrate nearly to boiling and precipitate the barium salts with ammonium carbonate and a little ammonia solution. Filter and wash, evaporate filtrate and washings to dryness, and ignite *below a red heat* till the ammonium salts are removed and the organic matter is oxidised as completely as possible. The residue, consisting of chlorides of potassium and sodium, with some charcoal and possibly a little barium salt, which escaped precipitation, is digested with hot water, a few drops of ammonium carbonate are added, and the solution filtered and washed. The filtrate and washing are again evaporated to dryness, and ignited gently.

The mixed chlorides are dissolved in water, an amount of platinum tetrachloride solution is added more than sufficient to form the double salt with all the potash and *soda* present, and the solution is evaporated at or below 100° C., so nearly to dryness that it becomes solid on cooling. To the cold mass 10 to 20 c.c. of strong alcohol (80 to 95 per cent) are added, and the mass is well broken up with a stirring rod or pestle. After standing 5 to 10 minutes the supernatant liquid, which must have a reddish colour from excess of platinum tetrachloride, is poured on a filter, more alcohol is added to the mixture of the double salts, and the whole stirred and pulverised and washed by decantation until the washings are perfectly colourless.

The precipitate is then brought on the filter by means of a wash-bottle containing alcohol. The salt is dried at 100° C. and weighed. After weighing, the salt is dissolved from the filter with hot water, and the filter is dried and weighed together with any platinum which may have been reduced in drying down the solution with platinum tetrachloride or other impurities.

The actual potash is reckoned from the weight of the double chloride of potassium and platinum by multiplying by 0·19308.

Potassium chloride is reckoned from the double salt by

multiplying by 0·3056. These factors are based on the following atomic weights:—

Platinum	197·18
Potassium	39·13
Chlorine	35·46
Oxygen	16·00

At the same meeting a committee was appointed, consisting of H. W. Wiley, W. J. Gascoyne, and Clifford Richardson, to examine anew the subject of potash determination and report at the annual meeting of the Society at Washington, September, 1885.

Glancing at the method used for estimating potash in fertilisers in other countries, the following points are brought to view:—

The method in use in Germany twenty years ago for estimating potash in crude kainite is given by Stohmann.*

(1.) Precipitation of sulphuric acid with barium chloride, separation of the magnesia by barium hydrate, precipitation of calcium and excess of added barium by ammonium carbonate, evaporation, and ignition, and final estimation of potash by platinic chloride.

(2.) The liquid after treatment with barium chloride is evaporated to dryness with oxalic acid, the residue ignited, the chlorides dissolved in water, the magnesia filtered off, and the potash estimated with platinic chloride.

To avoid the repeated filtration the following method was employed:—

(3.) About 10 grms. of the finely-powdered salt are treated with 300 c.c. hot water brought to a full boil and without minding the insoluble portion treated drop by drop with barium chloride. The barium sulphate settles rapidly, and, therefore, with care almost all excess of barium can be avoided. The whole, after cooling, is made up to 100 c.c., the volume of the precipitate having little influence on the result.

It is now filtered, and 100 c.c. of the filtrate corresponding to 1 grm. of the salt mixed with a solution of platinic chloride, which contains at least 2 grms. of platinum. This is now evaporated to dryness on the water-bath, treated with 80 per cent alcohol, rubbed up with a glass stirring rod, and washed by decantation until colourless. The whole is then brought on to a weighed filter, dried at 100°, and weighed.

(To be continued.)

THIRD REPORT OF THE COMMITTEE†

RE-APPOINTED FOR THE PURPOSE OF DRAWING UP A STATEMENT OF THE

VARIETIES OF CHEMICAL NAMES WHICH HAVE COME INTO USE,

FOR INDICATING THE CAUSES WHICH HAVE LED TO THEIR ADOPTION, AND FOR CONSIDERING WHAT CAN BE DONE TO BRING ABOUT SOME CONVERGENCE OF THE VIEWS ON CHEMICAL NOMENCLATURE OBTAINING AMONG ENGLISH AND FOREIGN CHEMISTS.‡

Brooke, Simpson, and Spiller, Limited. — The letters of allotment and regret were posted on Saturday. The amount of shares applied for was nearly three times in excess of those offered.

On the Risk of Fire from Nitric Acid.—G. Lechartier.—The author points out that if nitric acid, of the sp. gr. 1.50 or upwards, comes in contact with straw, *e.g.*, by the fracture of a carboy, the heat liberated is, under many circumstances, sufficient to set up spontaneous ignition.—*Comptes Rendus.*

THE CHEMICAL LABORATORIES AT UNIVERSITY COLLEGE, LIVERPOOL.

THE new Chemical Laboratories in connection with University College, Liverpool, which were opened on the 22nd inst. by the Earl of Derby, mark a new and important step in advance, being the first instalment of building undertaken by the College on a scale of academical completeness. A chair of chemistry was included in the original scheme of the College, promulgated in 1878, and endowment for the same was eventually provided by the munificence of Mrs. Grant, of Rock Ferry, who contributed a sum of £10,000 for this express purpose. Dr. Campbell Brown, who for nearly fifteen years had held the position of Lecturer in Chemistry to the Medical School, was elected Professor shortly after the opening of the College in January, 1882, and both before and since that time has, among many other services to the College, spent unwearied pains on providing suitable equipment for the important department committed to his charge.

The entire block is designed for the various branches of chemical study. The work was entrusted to Mr. Alfred Waterhouse, R.A., whose previous experience in the erection of similar laboratories for the Owens College, the Yorkshire College, and the Central Technical Training College at South Kensington, have given him unrivalled mastery among English architects of this particular branch of building. The plans of all the most important Continental laboratories, as well as of those in Great Britain, were carefully studied in designing the plans, and all the latest improvements in ventilation, fittings, and internal arrangements have been carefully compared, and, where practicable, embodied or adapted.

The buildings occupy the western confines of the College site, and are placed in immediate and convenient connection with the Medical School block. The west front contains the principal entrance, which is surmounted by the water-tower, while the eastern elevation looks out upon the College grounds. The most characteristic feature in the building is the large pentagonal apse, which looks southwards, and forms the containing wall of the large lecture and practical theatres, which have been designed expressly with a view to lecturing requirements.

The polygonal angles are relieved with buttresses running up the entire height of the building, and terminating in ornamental head-pieces in terra-cotta. The lower theatre is lighted with dual windows introduced in each of the five polygonal facets, while corresponding ornamental arcading is introduced in the exterior facets of the upper theatre, which (to facilitate artificial darkening) is in part lighted from the roof. This outer polygonal apse is flat-roofed, backed by the gable roof that is carried the full length from side to side of the interior portion of the theatre.

The main front is enriched by the entrance porch and tower, which intervene between the large lecturing theatre annexe and the body of the building, which contains the various supplementary laboratories, museums, and class-rooms, while the tower itself is occupied by the main staircase and minor rooms. The central portion of the building is designed in three gables facing the street, and is built in three storeys. Near one end of this rises the bold and lofty chimney, rendered necessary by the elaborate furnace and ventilation arrangements, which will be described later.

The entire design will be eventually completed by the erection of two large laboratories for qualitative and quantitative analysis placed side by side.

The practical theatre is specially arranged for a large class of students to follow by actual experiment on their own part the demonstrations given by the lecturer, whose table is placed in the middle of the room a few feet away from the back wall and between the entrances. The students' working benches are fifty-two in number, and are arranged in six concentric rows rising one above the other. These rows form segments of circles described from the lecturer's position as a centre. It is hoped that by this arrangement the acquisition of a knowledge of elementary practical chemistry will be greatly facilitated and rendered more thorough. The containing wall of the room opposite the lecturer is itself polygonal. The practical theatre measures 48 feet 6 inches in width and 42 feet 6 inches from the wall behind the lecturer to the centre of the opposite wall. The height of the room is 19 feet 6 inches. There are lofty windows in the polygonal walls and also at both sides of the room. The working benches for students are arranged in pairs, each pair having a small fume chamber and porcelain sink in common, but provided with separate cupboards, drains, gas nozzles, &c. Each student has 4 feet of bench length, the dual bench being about 8 feet long. The lecture table is 20 feet long and 3 feet wide, fitted with every necessary appliance, and on the wall behind are blackboards, fume chambers, cupboards, and shelving. Large fume chambers are also provided for the students' use in addition to the small ones provided in their benches.

Close to the preparation room and practical theatre is the sulphuretted hydrogen room, twenty feet six inches by fourteen feet, with special ventilation and niches for the supply of that malodorous gas for students' use. The remainder of this lower floor of the building is occupied by two rooms for storage, each twenty-two feet by sixteen feet three inches, a lavatory of the same size, retiring rooms for students, heating apparatus, fan chamber, and coal cellar. It may here be stated that the building generally is supplied with warmed fresh air, heated by hot water in large channels below the ground floor, and rising through vertical flues in the thickness of the walls to the various rooms. The fresh air is cleansed by passing through a sheet of water as it enters the building, and its entrance is accelerated by a fan driven by a gas-engine, and also by the method adopted for the extraction of foul air. The chemical fumes from the various fume chambers and other appliances, as well as the naturally vitiated air of the rooms, are drawn downwards through special extraction flues to the base of the upcast ventilating shaft, whose draught is accelerated by the spare heat from the adjacent smoke flue, aided when desired by an open furnace, which can be lit at the base of the shaft. Hot water for drawing off at various points in the building is provided by a separate service, and steam is also laid on for heating students' air ovens, for evaporation and distillation, and to such places as are likely to require its use in experiments. The heating apparatus is arranged to give a temperature of 60° when the external temperature is 25°.

Ascending the principal staircase to the second floor we find the corridors arranged as on the basement, the two southern ones leading to either side of the lecture theatre, and including between them the area and a preparation room for the service of the lecture theatre. The lecture theatre is forty-two feet six inches long and forty-eight feet six inches broad. It has three lofty windows at each side and two sky-lights at the back part of the room, while at night it is lighted by three Bower gas lights; the lecturer has the power of darkening it in the daytime for any special purpose by screens of opaque blinds running in grooves. The seats are arranged in concentric segments of circles having the lecturer's position as their centre, so that every one directly faces the lecturer. It is intended to seat 212 students with sufficient room to use the book-boards for writing and taking notes of the lectures; but 260 can be seated in the ordinary way. The lecture table is twenty-five feet long by three feet wide, and is provided with gas, steam, hot and cold water, with oxygen, hydrogen, and sulphuretted hydrogen supplies; separate taps on the table communicate with an air blast and a vacuum, while wires bring a current of electricity when required. Two flues opening on the table convey fumes and offensive gases to the main upcast shaft.

The table is also provided with a pneumatic trough, a mercury trough, and other conveniences. Behind the table are cupboards for reagents, blackboards, and diagram racks. Overhead is a cove in the ceiling for the purpose of deflecting outwards to the audience the sound of the lecturer's voice. In the wall behind the lecture table is a large fume-chamber, whose glass doors open to the lecture room in front and to the preparation room behind, a powerful draught on each side communicates with the main ventilation shaft. The base of this fume-chamber is a granite table, which is set on rails and can on occasion be moved forward to the lecture table or backward into the preparation room, which also communicates directly with the theatre by a door in the rear of the lecture table.

An ante-room for lecturers, and a large room for apparatus and diagrams, adjoin the lecture theatre. The north corridor of this floor communicates with a private laboratory for a few of the most advanced students, with the professor's room adjoining; a small class-room twenty-two feet by sixteeen feet three inches; and on the other side a chemical museum twenty-eight feet by twenty-four feet.

A staircase leads to two small rooms in the tower and the large water cistern; and also gives access to a lead flat, and a range of storage rooms in the roof. A lift travels from the basement to this storage floor. If we descend the principal staircase to the first floor landing we reach a corridor corresponding to that on the other floors. At the far end of this corridor is the east entrance from the college grounds. South of the corridor are rooms for gas analysis, a room arranged for operations in sealed tubes and other special operations in organic chemistry, a dark room for photography, photometry, &c., and a ladies' cloak room and lavatory. The corridor running north leads on the east to the organic laboratory (twenty-eight feet six inches by twenty-four feet), which will be used temporarily as a quantitative laboratory. The walls are of cream and dark gold-coloured glazed bricks, and the room is supplied with hot and cold water, steam, hot air baths, fume chambers, evaporating niches, and chambers for organic combustions and other conveniences. West of the corridor are three rooms, each twenty-two feet by sixteen feet three, viz., a room for water analysis and distillations requiring steam; a balance room also used as a reading and writing room—to which it is hoped friends will contribute books of reference—and a gas furnace room intended ultimately to communicate with the future large quantitative laboratory. Arches at the end of the north corridor are bricked up at present; but will ultimately lead to the large quantitative and qualitative laboratories, each sixty feet by thirty feet.

PROCEEDINGS OF SOCIETIES.

PHYSICAL SOCIETY.

March 13th, 1886.

Prof. BALFOUR STEWART, President, in the Chair.

THE following were elected Members of the Society:—Prof. U. S. Pickering and Mr. A. C. Hayward.

The following communications were read:—

"*On the Growth of Filiform Silver.*" By Dr. J. H. GLADSTONE.

It has long been known that if a piece of metallic copper be placed in a solution of nitrate of silver, replacement of one metal by the other will take place, the silver being deposited in the crystalline form, sometimes having a resemblance to fern leaves, or as superposed hexagonal lates, or knobs. It was observed, however, as far back as 1872, by the late Mr. Tribe and the author, that if nitrate of silver were decomposed by suboxide of copper, instead of the metal, the silver presented itself in threads, which rarely, if ever, bifurcate, but frequently turn at sharp angles or twist in every direction. This was described in the British Association Report for 1872, and it was observed that the same forms occurred in native silver. More recent observations have shown that the particular character and rapidity of formation of these threads depend very much upon the strength of the solution and the condition of the suboxide. Hydrated suboxide will scarcely decompose a 2 per cent solution, even after standing. The threads, which bend at a sharp angle, usually do so at 60° or 120°; other threads, however, are symmetrically curved, but, especially in strong solutions, they are given to twisting about in every direction, and generally terminate in irregular knobs of silver. As a rule a thread continues to grow of the same thickness as it commenced, but it sometimes enlarges for a while into a flat plane, or becomes encrusted for some distance with small crystals of silver. When the solution is very nearly exhausted of silver, fine arborescent forms appear; but with the suboxide there are never produced the fern-leaved forms, or hexagonal plates, or the other distinctly crystalline structures which characterise the growth from metallic copper. During the reaction the suboxide is changed into black protoxide and metallic copper, which dissolves; and the change will take place as well with the acetate and sulphate as the nitrate. If a mixture of suboxide and metallic copper be employed, not only do the distinctly crystalline and the filiform forms make their appearance, but strange intermediate forms come into existence.

"*Apparatus for Measuring the Electrical Resistance of Liquids.*" By Prof. REINOLD.

The apparatus consists of two bottles connected by a horizontal tube. The whole is filled with the liquid to be examined and immersed in water, by which means, and by thermometers inserted in each bottle, the temperature may be regulated and accurately ascertained. The electrodes are platinum plates, one dipping into each bottle. Two fine tubes terminate near the ends of the connecting tube, and electrodes are fitted into them at some distance from the ends: by connecting these to a quadrant electrometer, or a condenser and galvanometer, the difference of potential between the ends of the tube can be compared with that at the ends of a known resistance in the same circuit.

"*On Chromatic Photometry.*" By Capt. ABNEY and Lieut.-Col. R. FESTING. (This paper had been previously communicated to the Royal Society.)

A series of experiments have been made by the authors to determine the comparative luminous effect of different parts of the spectrum. A monochromatic light from any part of the spectrum of the electric arc was obtained by a method devised by Capt. Abney, and previously described by him to the Society [Physical Society, June 27, 1885]. The photometric effect at different parts of the spectrum was compared with that due to a candle at different distances by Rumford's photometer. In using this it was found best to place the candle in a given position, and obtain a balance by moving the slide upon which the spectrum was formed, and through a slit in which part of the light was allowed to pass, rapidly to and fro. For each position of the candle there are thus two corresponding positions of the slit. From the results of these observations a curve may be drawn showing the luminosity at different points. From the method by which it is obtained it is evident that the curve of one observer is not directly comparable with that of another, since a deficiency of perception in any part of the spectrum would affect the light of the candle as well as that examined. Since, however, the curves obtained by a great number of persons coincide very closely with those obtained by the authors, they have felt justified in adopting them as the normal curves. In the case of the electric arc the normal curve attains a maximum rather nearer the red end of the

spectrum than the blue. Assuming the normal curve, any other curve may be compared with it by increasing or decreasing its ordinates so that no part of it shall lie without the normal curve: in curves thus obtained, several of which were shown, deficiency in colour perception is often very clearly marked. By the use of two or more slits in the movable slide experiments were made upon mixtures of colours, and it was found in all cases that the luminous effect of a mixture of colours was the sum of the luminous effects of its components. It was also found that the colour of the comparison and the quantity of light admitted to form the spectrum were without effect upon the form of the curve. Light from the sun and from an incandescent lamp were similarly examined, though it should be observed that the result for sun-light differs notably from that given by Maxwell. An examination has also been made by light after passing through a turbid medium, and an expression of Lord Rayleigh's—

$$I' = Ie^{-x\lambda^{-4}}$$

where I is the original radiation, I' that after passing through the medium, λ the wave-length of the light, and x a constant depending upon the medium, has been closely verified.

CORRESPONDENCE.

"AN IMPORTED ART."

To the Editor of the Chemical News.

SIR,—As a chemist fairly conversant with the "literature" upon the preparation and characters of the mineral colours, I beg to ask—in the interest both of chemists and artists—for your kind permission to add a few words to the notice of Mr. H. C. Standage's "Artists' Manual of Pigments" (CHEMICAL NEWS, vol. liii., p. 118).

Of the actual value of the information contained in the volume in question there can be, as your reviewer remarks, no manner of doubt, inasmuch as I find it mainly consists of a long series of unacknowledged extracts, direct and indirect,—mostly direct,—from the valuable and well-known edition of "Field's Chromatography," by Salter, published by Messrs. Winsor and Newton in 1869. We are thus afforded interesting evidence of the progress of an art amongst us which—like the Colorado beetle—we have hitherto fondly thought indigenous to America, viz., that of the author whose "works" may be said to be the result of "*moments of abstraction.*"

The extent of the wholesale appropriation in the book before us is remarkable. In his short preface Mr. Standage makes no mention whatever of the sources of his information, nor of his indebtedness to any text-book or authority upon the subject. The general reader will naturally infer that the pages which follow are in some part chronicles of the author's labours, or that the letterpress, at least, is original. Upon examination, however, they prove to be—so far as the colours described are concerned—a curious and interesting, if not a very ingenious, mosaic, consisting almost entirely of paragraphs, sentences, phrases, and obvious paraphrases, taken direct from Field's volume: these are sparingly interspersed with a few at present unidentified sentences, which, from not having been traced to any other source, and from their frequent inaccuracy, I am inclined to attribute to Mr. Standage himself.

Let anyone who may think this an exaggeration carefully compare, as I have this afternoon done, the ten pages devoted to green pigments with the same section in "Field's Chromatography," and it will be found that no less than seven pages are "mosaiced" direct; paragraphs and sentences inserted verbatim; sentences clipped, inverted, and transposed, linked together or separated under fresh headings. Half a page is occupied by an *acknowledged* quotation from Bouvier, and the balance is composed of such obvious "remarks," "conditions of permanency," "tests for adulterations," &c., as can be inferred or paraphrased from the foregoing.

Turning thence, at haphazard, I opened the leaves at "Orient Yellow"—reprinted entire; "Mars Red," ditto; "Carmine," part reprint, part mosaic; and so on with all the other colours I have compared. This, too, with only one pair of inverted commas to a ten-line reprint (viridian), which, however, has no accompanying reference. In the whole book Salter's name is only mentioned twice, in connection with some trivial fact, whilst that of Field is honoured by exclusion. In one of the final chapters the student is referred to various works, from which more precise details may be obtained wherewith to satisfy the cravings of the Science and Art Department Examiner; yet here also all mention of "Field's Chromatography" is rigorously—or, as the author remarks in a similar passage, "vigorously"—excluded.

The author's scientific status may be gauged by his *naïve* remark on the now almost universally accepted theory of primary colours, and of the secondary nature of yellow. He says:—"I cannot here enter into the question of which colours should be considered as true primaries, but from my own knowledge of colour science I remain steadfast to the old original theory of *red*, *yellow*, and *blue* being the three primaries."

The value of the original sentences which embellish the work, and serve to mortar together the more solid paragraphs of information, may be gathered from the following, culled in addition to those noticed by your reviewer:—"*Venetian ochre;* sulphate of iron prepared by calcining sulphate of iron." Venetian ochre is, of course, Fe_2O_3. "Red ochre, usually a sulphate of iron, or ferric sulphate": *usually* peroxide of iron also. "Vermilion . . . must not be used with iodine, since it does not dry quickly." (!) Who, outside of Hanwell, *would* use iodine, or even an iodide,—not excepting HgI_2,—in painting a picture! "Thénard's blue, a salt of calcium calcined with alumina or oxide of tin": in reality stannate of cobalt; and this *gem*—"Baryta White: in composition it consists of 137 equivalents of barium, 32 of sulphur, and 64 of oxygen; the constituents in these proportions constitute the *neutral* sulphate of baryta. *Note.*—Sometimes this white is not entirely freed from sulphuric acid, in which case it has two equivalents of hydrogen, and is known as the acid sulphate of baryta." Really! If Mr. Standage refers to the compound $BaH_2(SO_4)_2$, I may remind him that it is only produced in small quantities by prolonged immersion of an insoluble barium salt in concentrated sulphuric acid, and is immediately decomposed by water. These samples of chemical knowledge are unfortunate if we judge them by a sentence in the Preface:—"This ignorance (of the modern artist) is due to his being practically unacquainted with the chemical nature and qualities of his pigments and vehicles."

In leaving all expressions of the value of the "Artists' Manual of Pigments" to the readers of it and of these few lines, I cannot but recall Dr. Johnson's famous *mot* on a like occasion:—"There is much in your book, sir, which is both new and true; but that which is new is not true, and that which is true is not new."—I am, &c,

H. LIVINGSTONE SULMAN.

Laboratory, 14, Chetwynd Road, N.W.,
March 17, 1886.

THE SPECTRA OF ERBIA.

To the Editor of the Chemical News.

SIR,—In reference to Mr. Crookes's observation in his recent paper on erbia, that this earth when illuminated with sunlight or electric light gives a spectrum with dark bands, I should like to state that I have frequently noticed the same effect with many solid compounds of

erbium and didymium, and ordinary daylight suffices to give a very distinct spectrum of dark lines similar in every respect to the absorption spectrum of the compounds in solution. The spectra were only examined with a small pocket-spectroscope, and a closer comparison would probably reveal some slight differences.

I believe it is better known that the two earths when heated to redness (best with phosphoric acid on a platinum wire in a Bunsen burner) give spectra of bright lines corresponding to the dark lines of their absorption spectra.

These two phenomena are what were to be expected from the abnormal absorption and the accepted laws of radiant energy.—I am, &c.,

T. S. HUMPIDGE.

Aberystwith, March 22.

AN EXAMINATION QUESTION.

To the Editor of the Chemical News.

SIR,—Having been desired, at examination, to state what products would be obtained by the action of phosphorus trichloride upon glacial acetic acid, I answered that the reaction gave acetyl chloride and phosphorus acid.

Being afterwards told that I should have included hydrochloric acid, I referred to the text-books, beginning with the most recent.

Morley (1886) gives no HCl in the equation (in which acetic acid is $C_2H_3O.OH_2$), but directs that the mixture be "warmed until no more hydric chloride escapes." Remsen (1885) gives no HCl. Armstrong (1884), Roscoe and Schorlemmer (1881), Fownes-Watts (1877), Schorlemmer (1873), Frankland (1872), also give no HCl.

Miller (1869) does give HCl as one of the products, as does Watts's translation of Gmelin (1856), on the authority of Béchamp (*Comptes Rendus*, 1855).

Thorpe (1880, *Journ. Chem. Soc.*, xxxvii., 186) gives the equation $3C_2H_4O_2 + 2PCl_3 = 3HCl + P_2O_3 + 3C_2H_3OCl$, and his experiments were confirmed by those of John Muir.

I shall be thankful if any of your readers can tell me where to find the account of experiments which contradicted those of Thorpe and Muir and led Roscoe and Schorlemmer, Armstrong, Remsen, and Morley to omit the HCl from their equations.—I am, &c.,

AN OLD STUDENT.

PS. I find that in "Miller's Organic Chemistry," edited by Armstrong and Groves in 1880, the equation given by Miller in 1869 has been corrected (?) by omitting the HCl.

CHEMICAL NOTICES FROM FOREIGN SOURCES.

NOTE.—All degrees of temperature are Centigrade unless otherwise expressed.

Comptes Rendus Hebdomadaires des Séances, de l' Académie des Sciences. Vol. cii., No. 10, March 8, 1886.

Isomeric States of Chromium Sesquichloride.—A. Recoura.—The author here describes the grey modification. He recognises two isomeric states of the sesquichloride; the green, with which is connected the anhydrous violet form, and, on the other hand, the grey. If dissolved in water these two varieties constitute two extreme states which may be transformed into each other by passing through all the intermediate conditions. The blue-grey solution is the stable state for dilute solutions and the green for those which are concentrated.

A Compound of Methylic Alcohol and of Copper Sulphate.—M. de Forcrand.—If pure anhydrous methylic alcohol is allowed to react in the cold upon anhydrous copper sulphate a green colour quickly appears either in the mass of copper sulphate or in the liquid. This colour is due to a compound of the two bodies slightly soluble in an excess of methylic alcohol. The higher homologues of methylic alcohol do not form similar combinations.

Action of Ammonia and Water upon Chloroform.—G. André.—The author obtains ammonium formiate and hydrochlorate and carbon monoxide. If the temperature has not exceeded 180° there remains a portion of unaltered chloroform.

Action of Picric Acid upon Turpentine and Thymene.—M. Lextreit.—Picric acid combines with oil of turpentine, forming a compound which approximates to the borneols. With thymene the result is similar.

Journal de Pharmacie et de Chemie.
Series 6, Vol. xiii., No. 4, February 15, 1886.

A Substance sold under the Name of Crystallised Hopeine.—A. Petit.—This substance, though having a slight odour of hops, has in its appearance, its crystalline form, and in all its reactions a close resemblance to morphia.

Ureometer.—F. Bellamy.—This instrument cannot be described intelligibly without the aid of the accompanying illustration.

Study of the Principal Red Colouring-Matters of Coal.—M. Frehse.—The author's point of view is the recognition of coal-tar reds as used for the colouration of wines, bon-bons, &c. He gives methods for detecting ponceau, soluble red, roccelline, "purple," Bordeaux red, violet I, orchil red, the croceines, ponceau A, acid magenta, ordinary magentas, with garnet, grenadine, cerise, roseine, geranium, the eosines, safranine, rosaline, Biebrich red, rose Bengale, Magdala red.

Experiments on Fatty Matters.—MM. Dubois and Padé.—Already noticed.

Note on the Determination of Oxygenated Water.—C. Blarez.—The author refers to a method and an apparatus for this purpose proposed by M. de Thierry, and remarks that he has for some time utilised this reaction for the same purpose.

Ferric Chloride with Potassium Ferricyanide as a Reagent.—MM. Hager and Reeb.—Fifteen drops ferric chloride (sp. gr. 1·280) and 15 drops of a saturated solution of potassium ferricyanide are mixed with 60 c.c. of water, acidulated with 5 drops of hydrochloric acid (sp. gr. 1·061). If a reducing agent is brought in contact with this test the colour turns from red to blue in consequence of the formation of Turnbull's blue. The solvents such as alcohol, ether, chloroform, amylic alcohol, benzol, have no effect. The blue colour should appear instantly, or at furthest within eight to ten minutes. The presence of morphine in a salt of quinine is thus shown with great ease. The author gives tables of the substances with which it reacts and of those with which it is indifferent.

Toxicity or Non-Toxicity of the Compounds of Copper.—M. du Moulin.—Doses of ½ grm. to 1 grm. of basic copper acetate were administered daily to dogs and rabbits for six weeks without producing poisoning. Copper oxide and carbonate have been also administered to rabbits for a year without producing any appreciable injury.

Detection of Small Quantities of Albumen in Urine.—H. Bretet.—The author finds that the nitric acid test when it gives negative results is not always satisfactory. He therefore proposes that Méhu's test should also be employed, *i.e.*, the urine, which if not distinctly acid should be first acidulated with a few drops of acetic acid, is saturated with sodium sulphate, and coagulation is then effected by applying heat only to the upper part of the liquid.

Influence of Bile and Biliary Acids upon the Digestive Action of Pepsine and Trypsine.—MM. Chittenden and Cummins.—From the CHEMICAL NEWS.

Hæmostatic Liquid.—M. Rothe.—The young shoots of the nettle are extracted with alcohol at 60 per cent.

Disinfection of Rooms.—M. Koenig.—The author recommends mercuric chloride. The windows, chimney, &c., are carefully closed up and 50 grms. mercuric chloride are placed in any suitable vessel, which is then set on a pan of burning charcoal, the operator immediately leaving the room and closing the door. After about four hours he re-enters, with a cloth over his mouth and nose, and throws open the windows. After some hours of ventilation a slight stoving with sulphur is made to follow, which neutralises any remnants of mercury. This process not merely disinfects but destroys all kinds of vermin.

Separation of Strychnine from the Animal Organism.—M. Plúgge.—Sonnenschein's reagent (sulphuric acid and cerous oxide) is the most sensitive reagent for strychnine, being capable of detecting 0·0000005 grm. of strychnine. Strychnine passes into the urine in great part undecomposed. The elimination of strychnine from the animal system requires a long time. A week after a single dose has been taken traces of it may be detected in the urine.

Biedermann's Central Blatt fur Agrikultur Chemie.
Vol. xiv., Part 11.

Principles and Limits of the Purification of Putrid and Putrescible Waters.—Prof. Dr. J. König.—The author proposes to allow foul waters to trickle down and through wire nets, thus obtaining results fully equal to those of irrigation over meadows. He likewise passes furnace- and chimney-gases through sewage, &c., as disinfectants.

The Dephosphorisation of Iron by the Thomas Process, and its Significance for Agriculture.—Dr. M. Fleischer.—The bulk of the phosphoric acid in these slags is in combination with lime; a small portion possibly with magnesia. All the phosphoric acid may be extracted by continued treatment with water containing phosphoric acid, whilst the iron remains practically undissolved. Thomas slags give off far more phosphoric acid to soils than do apatites, coprolites, and other natural phosphatic minerals.

Gases in Floating and Submerged Leaves. — N. Gréhant and J. Peyron.—From the *Comptes Rendus*.

Experiments in Vegetable Physiology. — Prof. H. Hellriegel.—The author has examined whether the degree of concentration in which nitrogen occurs in the nutrient liquids of the soil has an essential effect upon its utilisation. The crops obtained in the experiments were found to depend solely on the quantity of the nitrogen present.

Experiments on the Uninterrupted Cultivation of Wheat and Barley at Woburn.—Dr. A. Voelcker.—From the *Journal of the Royal Agricultural Society*.

On a Ferment which inverts Cane-Sugar. — A. Ladureau. — The author points out the necessity of cleansing the saccharometer tubes with dilute hydrochloric acid, phenol, or salicylic acid. Washing with water is not sufficient.

Vol. xiv., Part 12.

On Nitrogenous Organic Compounds in Arable Soils. — Dr. G. Loges. — On evaporating hydrochloric extracts of arable soils, even though very poor in humus, the author invariably obtained black residues. On analysis these were found to be organic nitrogen compounds.

Weathering of Sandstones. — Julius Stocklasa.— Sandstones consist of grains of silica cemented together with calcium carbonate and calcium and aluminium silicates. Magnesium and ferrous carbonate were present only to a small extent. By the continued action of the atmosphere the cement is washed away, and the free silica remains in disconnected grains.

On Certain Plant Destroyers.—An entomological paper.

Importance of the Cellulose Fermentation for the Nutrition of Animals.—W. Henneberg and F. Stohmann. Cellulose is a food of great value, 266 parts being equal in value to 100 parts of fat.

Bulletin de la Société d'Encouragement pour l'Industrie Nationale. 3rd Série. Vol. xii., December, 1885.

Report given in by M. Aimé Girard on behalf of the Committee of Chemical Arts on the Researches of M. Livache with Reference to the Drying Power of Oils.—M. Livache has devised a new process for preparing what used to be called "boiled oils." He finds that if finely divided metallic lead is moistened with linseed oil oxygen is taken up to the extent of 14 to 15 per cent without the aid of fire, and consequently without danger. This reaction distinguishes the drying oils from the non-drying class.

Series 4, Vol. i., No. 1, January, 1886.

This issue contains no chemical matter.

NOTES AND QUERIES.

*** Our Notes and Queries column was opened for the purpose of giving and obtaining information likely to be of use to our readers generally. We cannot undertake to let this column be the means of transmitting merely private information, or such trade notices as should legitimately come in the advertising columns.

Hard Varnish.—Can any of your readers tell me where I can obtain a varnish which will stand a high temperature, such as boiling water, without softening or cracking.—H.C.

MEETINGS FOR THE WEEK.

MONDAY, 29th.—Medical, 8.30.
—— Society of Arts, 8. (Cantor Lectures). "Petroleum and its Products," by Boverton Redwood, F.C.S.
TUESDAY, 30th.—Institution of Civil Engineers, 8
—— Chemical, 8. (Anniversary.) Election of Office Bearers and Council.
—— Royal Institution, 3. "The Function of Circulation," by Professor Arthur Gamgee, M.D., F.R.S.
WEDNESDAY, 31st.—Society of Arts. "Methods for Rendering the Blind Self-supporting," by T. R. Armitage, M.D.
THURSDAY, April 1st.—Royal, 4.30.
—— Royal Institution, 3. "Electro-Chemistry," by Prof. Dewar, F.R.S.
—— Chemical, 8. (1). "The Determination of Boiling-points," (2). "The Action of a Red-heat on Chloroform," by Prof. W. Ramsay and Dr. S. Young. "The Use of the Electric Light to influence Chemical Change," by Dr. H. E. Armstrong, F.R.S. "Some Sulphur Compounds of Barium," by S. H. Veley.
FRIDAY, 2nd.—Royal Institution, 9. "Telescope Objectives; their Preparation and Testing," by Howard Grubb, F.R.S., F.R.A.S.
—— Society of Arts, 8. "The History of Archæology in India," by James Gibbs,, C.S.I., C.I.E.
—— Geologists' Association, 8.
SATURDAY, 3rd.—Royal Institution, 3. "The Astronomical Telescope," by Howard Grubb, F.R.S.
—— Society of Arts, 3. "Electricity," by Professor George Forbes, M.A., F.R.S.E.

FOR SALE.

COMPLETE SET (unbound and uncut) of

THE CHEMICAL GAZETTE,

A Journal of Practical Chemistry.

17 Volumes; from November, 1842, to December, 1859.

Address, "Publisher," CHEMICAL NEWS Office, Boy Court, Ludgate Hill, London, E.C.

FOR SALE.

Sulphuric Acid Works, facing the Thames.

Capable of producing 35 to 40 tons per week.—Apply, W. W., CHEMICAL NEWS Office, Boy Court, Ludgate Hill, London, E.C.

THE CHEMICAL NEWS.

Vol. LIII. No. 1375.

SUGGESTIONS AS TO THE CAUSE OF THE PERIODIC LAW, AND THE NATURE OF THE CHEMICAL ELEMENTS.*

By THOS. CARNELLEY, D.Sc.,
Professor of Chemistry in University College, Dundee.

The truth of the Periodic Law, as enunciated by Newlands, Mendeljeff, and Lothar Meyer, is now generally allowed by most chemists. Nevertheless but little has been done towards attaining a reasonable explanation of the Law.

The object of the present paper, therefore, is to offer a few suggestions on this subject.

The Periodic Law not only throws considerable light on many relationships and points of analogy which had previously been observed, but has also led to the discovery of numerous others of both theoretical and practical importance, and has opened up views of the elements and their compounds which have been of great service in attaining a correct knowledge of their mutual relationships.

Granting the truth of the Periodic Law, we cannot help theorising as to its cause, and thence, by a natural step, as to the nature of the elements themselves. Even long before the discovery of the law many chemists—more especially Gladstone, Cooke, Pettenkofer, Odling, Kremers, and Dumas—had pointed out certain numerical relationships existing between the atomic weights of bodies belonging to a given group, and had thence been induced to seek for explanations of such relationships. These chemists hence supposed that the elements belonging to the several natural groups were not primary, but were made up of two or more simpler elements. These considerations, as to the compound nature of the elements, were very ably discussed, more especially by Dumas and Gladstone (*Phil. Mag.* (4), v., 313; *Comptes Rendus*, xlv., 709, 731; xlvi., 951; xlvii., 1026). A perusal of their papers on this subject is extremely interesting in view of the more recent discoveries of Newlands, Meyer, and Mendeljeff, and show how nearly the law was detected prior to its first enunciation by Newlands in his "Law of Octaves."

The views of Dumas and Gladstone may be expressed somewhat as follows:—The atomic weights of any group of closely allied elements, when written down in numerical order, form an arithmetical progression represented by $a+xd$, in which a is the first term and d the common difference. Thus in the case of the magnesium group we have—

	Be	Mg	Ca	Sr	Ba
$a=8$ ..	8	24	40	88	136
$d=16$ ..	a	$a+d$	$a+2d$	$a+5d$	$a+8d$

Now this relationship, as pointed out by both Gladstone and Dumas, is exactly similar to that which holds in the case of the homologous series of organic chemistry. For example:—

Methyl	$CH_3=15=a$
Ethyl	$C_2H_5=29=a+d$
Propyl	$C_3H_7=43=a+2d$
&c.	

In other groups of elements, however, the relations are not so simple, and it is necessary to assume such a complex expression as—

$$a+xd+xd'+xd''+\&c.$$ Thus:—

$a=19$ ..	F	Cl	Br	I
$d=16{\cdot}5$..	19	35·5	80	127
$d'=28$ ..	a	$a+d$	$a+2d+d'$	$2a+2d+2d'$

The conclusions of these chemists, however, were more or less fragmentary, and referred only to particular and isolated groups of elements. At that time the Periodic Law had not been propounded, and more general conclusions were therefore impossible, for the *general* application of the above facts would have necessarily implied a discovery of the Law prior to that made by Newlands.

In the light of the Periodic Law I wish to make a general extension of the fragmentary conclusions of Dumas. But I propose to arrive at this extension from a totally different standpoint and in a totally different way. It is an extension to which I have been led quite independently of the previous suggestions of Dumas, Gladstone, and others. In brief, what I wish to do is to bring into juxtaposition the Periodic Law, and an extended generalisation of the analogy of the elements to the alcohol radicles. At the same time I should wish my conclusions to be considered rather as *endeavours* after truth than the truth itself.

These conclusions are based on the relationships which I have observed to obtain between certain physical properties and the atomic weights of the elements and those of their compounds.

The relationships to which I refer have in part been published in various periodicals, but I wish more especially to direct attention to three of these, viz.:—

1. In this paper (*Phil. Mag.* (5), xviii., 1) a careful comparison was made of the melting- and boiling-points, and heats of formation, of the normal *halogen* compounds of the *elements*, and it was shown that certain well-defined relationships existed between these properties,—relationships which were dependent in a marked manner on the atomic weight of both the positive element and the halogen.

2. This paper (*Phil. Mag.* (5), xx., 259) dealt in a similar manner with some of the physical properties of the normal *alkyl* compounds (methides, ethides, &c.) of the elements, and it was shown that the *same relationships* obtained as in the case of the corresponding halogen compounds.

3. In this paper (*Ibid.* (5), xx., 497) it was shown that both the normal halogen and normal alkyl compounds of the hydrocarbon radicles* exhibit (with one exception, see Table I.) relationships similar to those of the corresponding compounds of the elements.

The relationships which were found to exist among all the above four classes of compounds were very numerous, but there were ten which were especially of importance; and for the purpose of giving some idea of the weight of the evidence which these relationships furnish, it will be well to state, in the following table, the number of cases in which they have been applied in each of the above classes of compounds, and the number of exceptions:—

	No. of cases in which the rules have been applied.	Number of exceptions.
I. Halogen compounds of the elements	3248	180=5·5%
II. Alkyl ditto..	942	54=5·7 ,,
III. Halogen compounds of the hydrocarbon radicles	877	11=1·2 ,,
IV. Alkyl ditto..	1110	60=5·4 ,,
Total	6177	305=5·0 ,,

For the reasons pointed out in my first paper (*q. v.*) 5 per cent of exceptions is very small, and is due chiefly

* A Paper read before the British Association, Aberdeen Meeting.

* For the definition of these radicles see Table IX.

to errors in the experimental melting- and boiling-points; thus no less than forty-five of the above exceptions are due to the boiling-point of propane being taken too high.

Examples of the kind of relationships referred to are given in the following Tables (I. to VII.). The arrows show the direction in which the melting- or boiling-point alters with the atomic weight. In the case of the halogen compounds of the elements, both calculated (*Phil. Mag.* (5), xviii., 1) and experimental data are given, in order that the Tables may be more complete.*

* So far as the determinations of the molecular magnetic rotations of the halogen compounds of the hydrocarbon radicles, made by Dr Perkin (*Chem. Journ.*, 1884; *Trans.*, 577), will allow a conclusion to be drawn, these physical constants also exhibit relationships similar to those given below in the case of the melting- and boiling-points. If this be true it is very probable that the molecular magnetic rotations of the halogen compounds of the elements would behave in a similar manner.

(To be continued).

A NEW SEWAGE PROCESS.

By A. McDONALD GRAHAM, F.C.S.

Some years since, when acting as chemical adviser on a large colliery in the North of England, and being much interested in obtaining a thoroughly trustworthy method of estimating the sulphur in coal and coke, I was led to examine the process proposed by Mr. Teikichi Nakamura, student of the Imperial College of Engineering, Tôkiô, Japan, and described in the *Journal of the Chemical Society* for 1879.

In order to save your readers the trouble of reference I think it would be better to insert Mr. Nakamura's own description of the process, which is as follows:—"The process consists in heating the coal below a red-heat in contact with alkaline carbonates, by which the coal, whether bituminous or not, rapidly undergoes—without evolution of smoke—complete atmospheric oxidation in a manner hardly to have been expected. The details of the method are as follows:—I take 3 or 4 parts of sodium carbonate to 1 part of coal in very fine powder. Intimately mix, in a large platinum dish or crucible, with a dry glass rod, and heat the mixture in the dish or crucible, loosely covered, at first so gently as not to volatilise hydrocarbons,—that is, so that no smell, or only a very faint aromatic odour, is observable,—a matter which is much easier of execution than might be supposed. Keep at a low temperature for some time; then raise the heat by slow degrees, without letting it reach that of visible redness, until the surface, which is at first of a dark grey colour, becomes only faintly grey. No smoke or odorous gas should escape during the whole of the oxidation. When the surface becomes only faintly grey, raise the temperature to a faint red-heat and keep it stationary for about forty to sixty minutes, at the end of which time the mass will become almost perfectly white or reddish if the coal contains iron, from the complete combustion of the coal. The mass is then treated with water, filtered, and the sulphate is determined in the usual way. It is rather remarkable that coal, and even coke, is burned completely at so low a temperature. Alkaline carbonates seem, however, to have no chemical action, but to act simply mechanically. The spaces between the particles of the carbonates acting as chimneys, the oxygen wanted being of course taken from the air. The combustion travels from the surface towards the bottom. Stirring the mixture during the oxidation impedes the process instead of hastening it, probably by closing the passages left by the consumed coal. The alkaline carbonates unchanged to sulphate remain unaltered."

After a careful consideration of the above process, it occurred to me that this principle of slow oxidation might be made available for the production of a sewage precipitant in the first place, and also for burning off the precipitated organic matter and making the residual mud again of use for the purpose of defecating and clearing the sewage in those cases where the mud does not contain sufficient plant-food to make it of value as a manure, and after a number of experiments extending over several years I have succeeded in elaborating a process which is satisfactory to myself, and which works well in practice. In carrying out my experiments I have observed that when a large excess of pyrites are acted on by the process sulphurous anhydride is formed and passes off in the gaseous state, and sulphate of iron remains in the mixture. If any oxide is added to the mixture, such as oxide of zinc, iron, or manganese, then a sulphate of the metal is also obtained.

In order to obtain a good sewage precipitant by this process an oxide must be selected which will form a stable salt with sulphuric acid, and is not liable to peroxidise, and which can also be acted on any number of times; and it is absolutely necessary that this oxide should exist in large quantities, and be obtainable at a moderate price. Binoxide of manganese fulfils these conditions, and in order to form my sewage precipitate I take this oxide, and add to it iron pyrites in a fine state of division, more than sufficient to convert the whole of the oxide of manganese into sulphate. As a medium for conveying the oxygen of the air to the mixture I use about 5 parts of finely-divided clay to 1 part of manganese. This is cheaper than carbonate of soda, though somewhat slower in its action, and in the many experiments I have performed I have found that very few samples of clay are attacked during the operation. After well mixing the powdered binoxide with the pyrites and fine clay, I place them in a muffle furnace, and heat the mixture gently at first, and afterwards to incipient redness, or about 1000° to 1200° F. After heating for about three or four hours the oxidation will generally be found to be complete, and the whole of the manganese will be converted into sulphate, together with a part of the iron. The mass when cool should be sprinkled with water, and allowed to remain in a damp condition for a week or more.

Two chemists, of much experience as practical analysts, have examined the process quantitatively, operating upon 3 or 4 lbs. of the mixture, and have obtained excellent results.

In operating on the sewage the sulphates of manganese and iron may be used with a certain proportion of clay, which is a well-known defecator of sewage. Charcoal may also be associated with the manganese, &c., if the sewage is much discoloured. Should the sewage be acid, from the influx of chemical refuse or any other cause, it will be necessary to use a little lime; but in a general way the sewage will be found to be sufficiently alkaline to ensure the precipitation of the manganese and iron, and the constant use of lime should be avoided. An effluent water obtained by the addition of much lime to a sulphate of alumina or iron has been found by experience to generate sulphuretted hydrogen and other offensive gases.

The effect of clay in carrying down organic matter may be demonstrated by a simple experiment. Take 10,000 grs. of fresh urine, and, after allowing it to stand for two hours, agitate it well with 50 grains of clay previously dried and powdered. No alteration will be apparent in the urine at the close of the operation; but on carefully collecting the clay on a filter, and drying it at a temperature below 100° C., it will be found, by the soda-lime process, to contain about 4 to 5 per cent of ammonia. Of the action of the charcoal it is unnecessary to speak.

In order to convert the sewage mud into a useful precipitant it must first be dried. Formerly the drying process was attended with much difficulty and expense, but as the nature of the product to be treated has become better understood the drying difficulty has been to a great extent surmounted. It is found by experience that after such a precipitating medium as alumina, iron, or manganese has passed through the sewage, it has acquired a new property,—that of spontaneous heating when mixed with organic matter, &c. If, therefore, the mud obtained by the use of such precipitants on the sewage be deprived of superfluous water by means of a filter-press, and placed in heaps in a sheltered situation, a natural heating takes place, the thermometer frequently rising as high as 180° F. when inserted in the middle of the heap. This faculty of spontaneous heating has been attributed, and I believe correctly, to the small quantity of phosphoric acid recovered from the sewage by the precipitating medium. After this heating process has taken place the mud will be found to be in a dry and friable condition, and can be readily brought into a fine state of division. It should then be furnaced with sufficient iron pyrites to re-convert the manganese and iron into sulphates. The oxidation of the organic matter by this process is very complete, and not the slightest nuisance is caused by the operation.

Iron pyrites (smalls) are now practically unsaleable, and exist in enormous quantities. If copper pyrites are used arrangements can be made for recovering the copper. It is estimated that a ton of the precipitating mixture, containing about 15 per cent of the mixed salts of man-

ganese and iron, and 85 per cent of fine clay, can be prepared for about 16 shillings, and the mud can be regenerated for about 8 or 9 shillings per ton.

The effluent water produced by the use of the clay, sulphate of manganese, &c., is clear and free from smell. It will keep for any length of time in an open or close vessel without giving off unpleasant gases or developing organic germs.

THE DIASTATIC ACTION OF SALIVA, AS MODIFIED BY VARIOUS CONDITIONS, STUDIED QUANTITATIVELY.*

By R. H. CHITTENDEN and HERBERT E. SMITH.

(Continued from p. 148.)

c. Influence of Acid-Proteid Matter—(continued).

In the last series of experiments where 21·9 c.c. of B are used the amount of combined acid in the digestive mixture is but 0·00094 per cent HCl, so that where the smaller amounts of acid-reacting saliva are used the percentage amount of combined acid is very small indeed.

Increasing the amount of saliva used, and thereby the percentage of acid-proteid matter, brought us finally to a point where the acid-proteid matter failed to stimulate the diastatic action of the ferment, and even began to show a tendency to retard its action.

The following series of experiments, using saliva wholly undiluted, illustrates this point:—

Series XVI.

100 c.c. of filtered saliva were neutralised, requiring 32 c.c. 0·2 per cent HCl = A.

52·8 c.c. A = 40 c.c. of the original saliva required 12·15 c.c. 0·1 per cent HCl to combine with the proteids, making saliva B; the fluid was distinctly acid to litmus, and contained 0·0187 per cent combined acid. Three digestions were made with both A and B, using quantities of the fluids equal to 20, 10, and 5 c.c. respectively of the original saliva.

		Wt. Cu in one-eighth.	Total amount sugar.

26·4 c.c.	A ..	39·68 p.c.	0
32·48	B ..	38·96	0·00608 p.c.
Decrease ..		0·72	
13·2 c.c.	A ..	37·52 p. c.	0
16·24	B ..	39·73	0·00304 p. c.
Increase ..		2·21	
6·6 c.c.	A ..	34·79 p. c.	0
8·12	B ..	37·74	0·00152 p. c.
Increase ..		2·95	

In this series of experiments, where the percentage of combined acid in the digestive mixture is much greater than before, the same increase in diastatic action is noticed. With the largest quantity of saliva, however, where the amount of combined acid is 0·006 per cent, we seem to have reached a point where the acid-proteid matter ceases to stimulate and begins to retard the action of the ferment. That this is actually the case we have proved by another experiment confirmatory of the preceding one, using in the digestion, however, 2 grms. of starch instead of 1.

Thus, while an amount of neutral saliva equal to 20 c.c. of the original secretion converted 39·08 per cent starch into sugar, the same amount of saliva having all of its proteid matter combined with acid converted under the same conditions 38·21 per cent of the starch, a decrease of 0·87 per cent; in this case, however, the amount of combined acid present in the 100 c.c. of digestive mixture was 0·008 per cent.

It thus seems plainly proven that up to a certain percentage the presence of acid-proteid matter in the saliva tends to decidedly stimulate its diastatic action. We cannot therefore agree with Langley and Eves that ptyalin acts best in every instance in a neutral solution, for our results certainly show an increased action of the ferment in the presence of the acid-proteids, except where the latter are present in comparatively large amount.

The only possible fallacies which suggest themselves here are traces of undetectable alkali in the starch and the presence of phosphates of calcium or magnesium. This result, moreover, makes clear many statements previously recorded which would otherwise be difficult of explanation. Thus it has been recorded by Astaschewsky* that the saliva of the parotid gland possesses a very faint acid reaction, and that the maximum of the diastatic action of parotid saliva corresponds with the strongest acid reaction; but in these observations doubtless the acid reaction was in every case due to acid proteids, and not to free acid. Again it was found by one of us† that the presence of 0·005 per cent HCl decidedly increased the diastatic action of saliva, but while the observation was correct the result was wrongfully attributed to 0·005 per cent free acid when it should have been attributed to the same percentage of combined acid, where doubtless the proteid matter was not wholly saturated. Likewise Watson's‡ oft-quoted result, where the addition of a drop of strong acid to saliva gave him an increased diastatic action, was doubtless due to the acid-proteid matter formed, and not to free acid, though it may have been due to partial or complete neutralisation.

We endeavoured to ascertain whether the acid-proteid matter formed by the addition of acid to undiluted saliva would have any destructive action on the diastatic ferment when warmed at 40° C. Of course only a slight action, if any, could be expected, still it seemed of sufficient importance to warrant the experiment. Accordingly two mixtures were prepared as follows:—

	A.	B.
Saliva	20·0 c.c.	20·0 c.c.
HCl 0·2 p.c. to neutralise	6·8	6·8
HCl 0·2 p.c. to combine with proteids	—	3·2
H_2O	13·2	10·0
	40·0	40·0
	Neutral.	0·016 „ HCl combined.

These two solutions were warmed at 40° C. for one hour, then neutralising and equalising‖ mixtures were added, after which starch and water to 100 c.c. The results were in A a conversion of 38·68 per cent of the starch into sugar, and in B a conversion of 38·26 per cent, so that, while there may have been some little destruction of the

‖ Equivalent amounts of standard acid and sodium carbonate solutions, so that A, for example, might contain the same amount of sodium chloride as B.

ferment, it is plain that the diminished action noticed in the two preceding cases, in the presence of the larger percentages of acid-proteid matter, was probably due to simple retardation, since the percentage of combined acid was not more than half that in the above experiment.

We have studied the influence of acid-proteid matter on salivary digestion still further by experimenting likewise with peptones; and in studying the influence of acid-peptones on the action of the ferment we have been impressed with the striking effect of very minute quantities of acid on the ordinary action of peptones, increasing it very decidedly. It has already been shown that the presence of 0·05, 0·1 and 0·2 per cent of neutral peptone produces, in neutral solutions, a like increased diastatic action; with 0·5 per cent peptone the increase is as much as with 0·2 per cent,—that is, in the case of saliva considerably diluted. With acid-peptones, however, the effect produced is quite different, and the amount of combined acid necessary to produce this different effect is quite small.

Peptones as usually prepared contain a small amount of combined acid. The sample we used required per grm. 0·014 grm. Na_2CO_3 to make it neutral: this would be equivalent to 0·00964 grm. HCl. Consequently the percentage of combined acid in the peptone, assuming it to be hydrochloric acid, would be 0·964 per cent. With such an acid-peptone the following experiments were tried:—

Series XVII.

20 c.c. saliva were neutralised and diluted to 100 c.c.; of this solution 10 c.c., equal to 2 c.c. of original saliva, were used in each digestion. Four experiments were tried, in three of which 0·050 grm., 0·100 grm., and 0·200 grm. of the above acid-peptone were added. Following are the results, after warming the mixtures at 40° C. for thirty minutes.

Per cent peptone.	Wt. Cu in one-eighth.	Total amount sugar formed.	Starch converted.
0	0·0766 grm.	0·3128 grm.	28·16 p.c.
0·05	0·0873	0·3560	32·05
0·10	0·0897	0·3656	32·91
0·20	0·0929	0·3784	34·21

Comparing these results with those obtained by similar percentages of neutral peptone the difference is sufficiently striking, and yet the percentage of combined acid in the digestive mixture, where there is present 0·20 grm. of acid-peptone, is but 0·0019 per cent calculated as HCl.

Experimenting with peptones completely saturated with acid, and in this case with what was known to be hydrochloric acid, results similar to the above were obtained, with, however, several suggestive deviations. The following series of experiments will serve to illustrate the main points of interest:—

Series XVIII.

40 c.c. filtered saliva were neutralised and diluted to 200 c.c.; 10 c.c. of this diluted fluid were used in each experiment.

A standard solution of peptone saturated with hydrochloric acid was also prepared.

The following percentages of peptone and combined acid were contained in the different digestive mixtures of 100 c.c.

	Peptone. Per cent.	Combined HCl. Per cent.
1.	0	0
2.	0	0·0006*
3.	0·01	0·00057
4.	0·020	0·00115
5.	0·040	0·0023
6.	0·060	0·00345
7.	0·080	0·0046

* To saturate the proteids naturally present in the saliva.

Following are the results of the digestions:—

	Wt. Cu in one-eighth.	Total amount sugar.	Starch converted.
No. 1	0·0872 grm.	0·3560 grm.	31·85 p.c.
2	0·0896	0·3656	32·91
3	0·0901	0·3672	33·06
4	0·0935	0·3808	34·28
5	0·0892	0·3640	32·77
6	0·0775	0·3160	28·45
7	0·0495	0·2048	18·43

It is to be noticed, first, that in this series of experiments the peptones, being completely saturated with acid, are present in much smaller percentages proportionally than the combined acid is, and the effect produced is a diminished diastatic action in the case of Nos. 6 and 7, in the presence of an amount of combined acid which, in the case of the proteids naturally present in saliva, has no retarding action whatever, but on the contrary a stimulating action. The addition of a larger amount of peptone to Nos. 5, 6, and 7, for example, the percentage of acid remaining the same, tends to bring up the diastatic action very decidedly.

It would appear from these results, moreover, assuming that the combining power of peptone is the same as the proteids present in saliva, that the presence of say 0·003 per cent combined HCl in the form of saturated acid-peptone has a retarding action, while the same percentage of combined HCl in the form of saturated salivary proteids has, in the case of saliva of the same dilution, a decided stimulating action. At the same time it is to be remembered that when acid is added to saliva some considerable acid may be used by the inorganic salts with formation of acid phosphates, for example. These results, moreover, indicate that such is doubtless the case. Increasing the percentage of peptone to say 1 per cent admits of the addition of larger amounts of hydrochloric acid without particularly retarding the action of the ferment; thus, as Langley and Eves state, "0·0075 per cent hydrochloric acid may be added to saliva diluted 10 or 20 times, provided 1 per cent peptone be present, and yet its action on starch be about equal to that of the saliva without peptone or acid."

Again it would appear that small percentages of acid-proteid matter, either peptones or the albuminous bodies present in saliva, tend to increase the diastatic action not only beyond the natural action of the saliva, but also somewhat beyond the action of the saliva plus the same percentage of neutral peptone. Thus, while the presence of a few hundredths of 1 per cent of neutral peptone in saliva diluted 1:50 caused about 1·5 per cent increased conversion of starch, acid peptone cause in thirty minutes 2·17 per cent increased conversion. Again, as has been seen, the acid-proteids of saliva cause a like increase. Large percentages of acid proteids, however, in which the albuminous matter is completely saturated, distinctly retard the diastatic action.

These results harmonise in a general way with the previous results obtained by one of us,* in which it was found that the presence of 1 per cent peptone in an acid-reacting fluid, which by itself almost completely stopped the diastatic action of the saliva, increased the diastatic action of the ferment above the action of the neutral saliva and also above the action of the neutral saliva plus the 1 per cent of neutral peptone.

We next endeavoured to ascertain how much of the retarding action of the acid-peptone is due to destruction of the ferment. Without giving details we have found that with saliva ten times diluted there is a noticeable destruction of the ferment in the presence of 0·028 per cent of combined acid, although it is not great. In this case it is to be understood that the amount of peptone present is only such as would furnish this percentage of combined acid. The following percentages of starch converted

* Chittenden and Ely, *loc. cit.*

(after neutralisation and equalisation) show the amount of destruction under the different conditions.

SERIES XIX.

Length of time at 40° C.	Per cent combined HCl.	Per cent peptone.	Starch converted.
	0	0	31·65 p.c.
30 min.	0·014	0·25	31·18
30	0·028	0·50	30·82
60	0·028	0·50	29·74
30	0·057	1·00	27·73

It is thus manifest from our results that the retarding influence of the larger percentages of acid-peptones is out of all proportion to their power of destruction. Still larger percentages of acid-saturated peptones produce a much greater destruction. Thus, by warming 10 c.c. of a neutral dilute saliva (1 : 5) with a solution of peptone saturated with acid, in such proportion that the mixture contained 0·430 per cent combined HCl, there was in thirty minutes an almost complete destruction of the ferment.

(To be continued.)

ANALYSES OF COMMERCIAL FERTILISERS.*

(Continued from p. 150.)

Results of Method.

A MIXTURE containing 24·83 per cent potassium sulphate gave, by method 1, 24·52 per cent K_2SO_4; by method 2, 25·51 per cent K_2SO_4; by method 3, 24·58 per cent K_2SO_4.

It appears that treatment with oxalic acid tends to give somewhat higher results than are otherwise obtained, and this opinion is corroborated by some of the data to follow.

The use of oxalic acid to convert nitrates into carbonates was also suggested by Mr. Clifford Richardson.†

Nitrates are, after conversion into carbonates, readily obtained in the form of chlorides. It is doubtful whether a single evaporation with hydrochloric acid is sufficient to convert all nitrates present into chlorides.

G. Krause‡ gives the method in use a decade ago at Strassfurt for estimating potash. It is not greatly different from that described by Stohmann. The salt, after solution, is treated with the slightest excess of barium chloride, made up to a standard volume, and an aliquot part of the filtrate taken for the estimation. This is evaporated to dryness in a porcelain dish after treatment with an excess of platinic chloride. The residue is moistened with a few drops of water and then treated with 2 to 3 c.c. alcohol of 90 to 95 per cent, and well rubbed with a glass rod. It is then washed by decantation, and, after having been dried at 120° to 130°, weighed on a tared filter.

Since the potash of commercial fertilisers is derived almost exclusively from kainite the fact that precipitated barium sulphate constantly incorporates the portion of the potassium chloride formed must not be lost sight of. It is true this loss is trifling, but at least its existence should be recognised.

West‖ has studied the disturbing effect of this substance and recommends the use of a factor for correction of results of a magnitude depending on the amount of sulphuric acid present. This is previously determined by titration with barium chloride and potassium chromate.

Ulex§ recommends the use of a 20 per cent glycerin solution in connection with the platinic chloride solution. For a mixture containing 0·5 grm. potassium chloride he uses 5 c.c. of the glycerin solution and 10 c.c. platinic chloride sp. gr. 1·1. On evaporation the glycerin is left as a syrup, the crystals of the double salt are more perfectly formed, and much less alcohol is required for washing.

In 1880 Mr. R. R. Tatlock issued a circular in which he proposed to estimate potash in its salts as follows :—

Take 35 grms. of the sample, dissolve in water, filter, and make up to 500 c.c. Place 10 c.c. of this solution in a small porcelain dish, add 20 c.c. water and then 30 c.c. of the platinic chloride solution containing 7 grms. platinum in 100 c.c. Evaporate on water-bath, but not to complete dryness, add a few drops of water, evaporate a second time, and treat the precipitate with 2 c.c. of the platinic chloride solution, stirring well. Bring the precipitate on a filter and wash it with 1 c.c. platinic chloride solution, and then wash dish, precipitate, and filter with as little 95 per cent alcohol as possible Dry the filter on the water-bath, transfer the precipitate as completely as possible to a small platinum dish, dry at 100°, and weigh. Incinerate the filter, which still contains traces of the precipitate, weigh the residue consisting of platinum and potassium chloride, calculate as K_2PtCl_6, and add to weight of salt found in platinum dish.

Zuchschwerdt* and West compared the results obtained by this method with those given by the method of Fresenius and a modified method of their own. Two determinations by the method of Fresenius gave 100·013 and 100·005 per cent, respectively. A mean of thirteen determinations of the same salt (chemically pure KCl), by Tatlock's method, gave 99·683 per cent. Nine determinations of the same by the author's modified method gave 100·023 per cent.

The radical defect of Tatlock's method is found in the solubility of potassio-platinic chloride in solutions of platinic chloride. In any case the method could only be used successfully in the absence of other acids than hydrochloric.

Following is an outline of the method employed by Zuchschwerdt and West :—

Dissolve 10 grms. of the sample in 500 c.c. of water, filter and take 20 c.c. of the filtrate Add to this in a porcelain dish 7 c.c. solution of platinic chloride (7 grms. platinum in 100 c.c.). Evaporate to consistence of syrup with frequent stirring. By this means free hydrochloric acid is mostly driven off. After cooling add 10 c.c. 95 per cent, alcohol, wash with alcohol, on to a tared filter, dry at 110° to 115°, and weigh.

David Lindo† has made an extensive study of the estimation of potash as platinum double salt. When only sodium and potassium chlorides are present, he recommends the following method :—

The sample dissolved in water should not contain more than 1 per cent of the two salts. To this a solution of platinic chloride is added, containing by weight twice as much platinum as there are sodium and potassium chlorides present. Evaporate to dryness on water-bath and dry for two or three minutes. Cool and treat residue with 20 c.c., 98 per cent, alcohol, filter by upward filtration, and wash three or four times with small quantities of alcohol of the same strength as above. Rub the precipitate to impalpable particles in a little alcohol. Decant the alcohol, bring the precipitate on a tared filter, wash two or three times with alcohol, dry at 130° and weigh. In nineteen experiments with mixed chlorides, in which the sodium chloride varied from 20 to 30 per cent of the potassium, the mean of the potassium chloride obtained was 100·04 per cent. According to Lindo, K_2PtCl_6 is difficultly soluble in a half saturated solution of ammonium chloride. In the presence of sulphates, Lindo proposes to use a solution of ammonium chloride, previously saturated with platinic chloride. He experimented on a mixture of 65 parts potassium chloride, 25 parts magnesium sulphate, and 10 parts sodium chloride.

As a mean of ten experiments he found that he had recovered 99·99 of the potassium. For full details of the work I refer to the original papers, which are too long for further quotation.

Dreyfus* has proposed another modification for the estimation of potash. Ten grms. of the sample are incinerated after treatment with strong sulphuric acid. The ash is exhausted with hot water, the filtrate made up to 500, and 50 c.c. used for the potash determination by treatment with barium hydrate, filtration, and estimation with platinic chloride in the usual way.

An examination of the indirect methods of alkali estimation and of the disturbing influence of large quantities of sodium chloride on the direct estimation of potash as K_2PtCl_6 has been made by Dr. M. Kretschy.†

Interesting experiments in the estimation of potash in fertilisers may also be found in the report on the methods employed in the estimation of potash and phosphoric acid in commercial products prepared by Mr. A. H. Allen.‡

Dr. R. Fresenius‖ discusses the factor which should be employed for converting K_2PtCl_6 into KCl. He concludes, after carefully examining the results obtained by the several proposed factors, that 100 parts of K_2PtKCl_6 dried to a constant weight at 130° contain 30·56 parts of KCl.

(To be continued).

PROCEEDINGS OF SOCIETIES.

CHEMICAL SOCIETY.

Thursday, March 18th, 1886.

Dr. Hugo Müller, F.R.S., President, in the Chair.

Messrs. A. Dresel, Albert Ivatt, and Edward Willmore were formally admitted Fellows of the Society.

Certificates were read for the first time in favour of Messrs. Cosmo Innes Burton, 11, Upper Phillimore Gardens, W.; Arthur William Clayden, North Lodge, Bath College, Bath; Christopher Hodgson, 144, Blake Street, Barrow-in-Furness; John William King, St. George's Hospital, W.; Henry Oliver Minty, 731, Wandsworth Road, S.W.; Richard Lloydd Whiteley, University College, Nottingham.

The following papers were read:—

30. "*Note on the Combustion of Cyanogen.*" By Harold B. Dixon, M.A.

A few years ago, on discovering that a spark might be sent through a well-dried mixture of carbonic oxide and oxygen without causing explosion, the author made several experiments on well-dried cyanogen and oxygen. These experiments seemed to show that cyanogen, like carbonic oxide, would not explode when dry. On returning to this investigation last autumn, the author discovered that the non-explosion of cyanogen previously observed was due not to the absence of moisture, but to the insufficient temperature of the spark. A spark 1 m.m. long from a Voss machine may be passed through a mixture of cyanogen and oxygen without causing explosion or any appreciable decomposition of the cyanogen. A mixture of the gases dried by standing in contact with anhydrous phosphoric oxide for two months exploded with violence when a strong spark was passed through it. A similar mixture which had stood in contact with a stick of potash also exploded violently.

It was found that the initial rate of explosion of carbonic oxide and oxygen increased rapidly with the amount of aqueous vapour present in the mixture: similar experiments made with cyanogen and oxygen showed that the initial rate of explosion diminished on adding aqueous vapour. It seems evident, therefore, that the explosion of cyanogen and oxygen does not depend upon the presence of water, which merely acts as a diluent in the mixture.

The author has shown that when a platinum wire is raised to redness in a well-dried mixture of carbonic oxide and oxygen, the wire glows intensely for a short time, and that complete combination takes place between the carbonic oxide and oxygen without visible flame. A precisely similar phenomenon is observed when a platinum wire is raised to full redness in cyanogen and oxygen: the wire glows brightly, and the cyanogen is oxidised to carbon dioxide. The tube is filled with orange vapour both when the oxygen is present in excess and in defect, but to a smaller extent in the latter case. No flame is visible round the glowing coil of wire. When the wire is only raised to dull redness no action seems to take place; on breaking the circuit the wire cools immediately, but when once the action has begun the wire continues glowing half a minute after the circuit is broken.

Discussion.

The President remarked that it appeared to him that the cause of this remarkable behaviour of cyanogen just brought under the notice of the Society depended probably not so much on the greater heat effect of the larger—or rather the longer—spark as on its greater potential energy, which starts the explosive wave, for it is generally supposed that the degree of temperature in a small spark is much the same as that of a larger one of the same electromotive force.

Dr. Armstrong said that the study of the behaviour of mixtures of cyanogen and oxygen, in comparison with that of mixtures of carbonic oxide and oxygen, was of peculiar interest, as cyanogen was one of the few gases which decomposed with evolution of heat. It was well known that a certain minimum electromotive force was required to electrolyse liquids, and to effect the electrolysis of gases a minimum—relatively very high—electromotive force was doubtless also required: an explanation of Mr. Dixon's observations might perhaps be based upon this circumstance.

31. "*On the Constitution of the Naphthalene-Derivatives.*" By R. Meldola.

Having been unable to attend the meeting of the Society when Mr. Stallard read his paper on the bromophthalic acids published in the current number of the *Journal* (p. 187), I may take this opportunity of pointing out that the new proofs advanced by him in favour of the constitution $CO_2H : CO_2H : Br = 1 : 2 : 3$ for the bromophthalic acid of m. p. 174° to 176° appear to me to be perfectly conclusive. The same conclusion has, in fact, been simultaneously arrived at by Guareschi (*Atti d. R. Accad. d. Sci. d. Torino*, vol. xxi., January 24th, 1886), who has obtained a chlorophthalic acid of m. p. 124° (anhydride, m. p. 124° to 125·5°) by the oxidation of γ-dichlornaphthalene. The constitution of this chlrophthalic acid is analogous to that of the bromophthalic acid obtained by Smith, Guareschi, and myself, and the isomeric acid of Alèn, which has the constitution—

$$CO_2H : CO_2H : Cl = 1 : 2 : 4,$$

and melts at a lower temperature (148° according to Alèn, 130° to 134° according to Krüger).

In accordance with this evidence it becomes necessary to modify the formula of Guareschi's nitrobromonaphthalene (m. p. 122·5°) as proposed by Mr. Stallard, and as the discoverer has himself pointed out in the paper referred to. The formula given by me in my last paper (*Trans.* 1885, 513) for the dibromonaphthylamine of m. p. 105° must also be corrected, and I may here point out that the constitution of this substance and of its derived di- and tri-bromonaphthalenes can be now definitely established. The corrected formulæ will be—

* *Bul. Soc. Chem.*, 38, p. 162.
† *Zeit. Anal. Chem.*, 15, pp. 37 *et seq.*
‡ Chemical News, vol. xxxv., Nos. 917 and 918, and vol. xxxvi., Nos. 920, 922, and 923.
‖ *Zeit. Anal. Chem.*, 1882, pp. 234 *et seq.*

Dibromonaphthylamine, m. p. 105°, Br : Br : NH_2 = = 1′ : 1 : 3
Dibromonaphthalene, m. p. 74°, Br : Br = 1 : 1′
Tribromonaphthalene, m. p. 110°, Br : Br : Br = 1 : 1′ : 3.

The alternative formula Br : Br : NH_2 = 1′ : 4 : 2 for the dibromonaphthylamine is excluded, because it does not give γ-dibromonaphthalene on displacing the NH_2 group by H.

The dibromonaphthylamine of m. p. 101° to 102° (*Trans.*, 1885, 514) must accordingly have the constitution—

$$NH_2 : Br : Br = 1 : 3 : 3' \text{ or } 1 : 3 : 2',$$

but there is at present no evidence to decide which of these formulæ is correct. That the second Br. atom does not occupy an α-position in the unsubstituted nucleus appears from the fact that I failed to obtain the 1 : 2 : 3 bromophthalic acid from it by oxidation. Further, as this dibromonaphthylamine gave only a slight trace of phthalic acid when oxidised, it would appear that the second Br atom does not enter the substituted nucleus. Unfortunately I have not enough of the dibromonaphthylamine left to repeat the oxidation experiment, but I find on reference to my laboratory notes that the oxidation was twice performed with different preparations, and with the same result in each case. The minute quantity of phthalic acid formed certainly does not appear to me sufficient to establish the formula Br : Br : NH_2 = 3 : 2 : 1, which is the only other one admissible (*Trans.*, 1885, 514).

The chief discrepancy at present remaining to be cleared up is the apparent identity of the two dibromonaphthalenes of m. p. 74°. I have re-examined the specimens in my possession, and, as far as melting-point and crystalline form can be trusted as indications of identity, these two dibromonaphthalenes are certainly indistinguishable from one another; nevertheless they may be isomeric, as I have already pointed out (*Trans.*, 1885, p. 516) that naphthalene derivatives which are known to be isomeric may have the same crystalline form and melting-point. The question can only be decided by a further study of the derivatives of the dibromonaphthalenes in question, but I regret that the quantity at my disposal is much too small to enable me at present to extend the research in this direction. The bromophthalic acid used by H. v. Pechmann (*Ber.*, xii., 2126) may have been the meta-compound, the production of erythroxyanthraquinone from the corresponding bromobenzoylbenzoic acid being due to intra-molecular migration to the ortho-position on fusion with alkali.

I may take the present opportunity of pointing out that the dibromonaphthalene (m. p. 68°) obtained by Canzoneri (*Gazzetta*, xii., 424) from Smith's monobromo-β-naphthol, is in all probability identical with the orthodibromonaphthalene described in a former paper (*Trans.*, 1883, 5). It has been argued that the investigations of Beilstein and Kurbatow (*Annalen*, ccii., 228) show that β-dinitronaphthalene (m. p. 176°) has both NO_2 groups in the same benzene-ring, most probably in the meta-position (Jacobson, *Inaug. Diss.*, 1882, 37). If so, ζ-dichloronaphthalene (m. p. 83°), obtained by Atterberg (*Ber.*, ix., 1730) by the action of PCl_5 upon this dinitronaphthalene, is analogous to the metadibromonaphthalene (m. p. 64°) described by me in 1879 (*Ber.*, xii., 1962).

Discussion.

Dr. ARMSTRONG said that as regards the constitution of β-dinitronaphthalene, the production from it of *dinitrophthalic acid* (Beilstein and Kurbatow), by the action of nitric acid in sealed tubes, was not satisfactory evidence; and Jacobson's contention that Liebermann and Dittler's nitro-α-naphthol (m. p. 128°) could not well be an ortho-derivative because the amidonaphthol prepared from it did not furnish a quinone on oxidation, was equally unsatisfactory as being negative evidence; there was no obvious flaw in Atterberg's argument that ζ-dichloronaphthalene is an α-α-derivative ("Watts's Dictionary," vol. viii., Pt. II., p. 1376). The argument from analogy is apt to break down on comparing benzene with naphthalene, as two new "laws" come into force in the case of naphthalene, namely, the tendency for substitution to take place in both "rings," and the marked tendency to form α-derivatives. The formula given by Prof. Meldola to the dibromonaphthylamine melting at 101° to 102° must be accepted with reserve on this latter account.

32. "*Action of Ammonia on Chromyl Dichloride.*" By SAMUEL RIDEAL, B.Sc.

Dry ammonia gives with chromyl dichloride ammonium chloride, nitrogen, and brown oxide of chromium, the reaction being expressed by the equation—

$$3CrO_2Cl_2 + 8NH_3 = 6NH_4Cl + N_2 + Cr_2O_3 \cdot CrO_3.$$

No addition products or chromammonium bases are formed when the vapour of chromyl dichloride burns in an atmosphere of dry ammonia under the ordinary temperature and pressure. This explanation of the reaction agrees with the observation of Persoz, that 20·98 parts of chromyl dichloride absorb 79·1 parts of ammonia.

33. "*Note on the Estimation of Resin in Soaps.*" By C. R. ALDER WRIGHT, D.Sc., F.R.S., and C. THOMPSON, F.C.S.

We have had occasion to make a number of experiments with various of the methods hitherto proposed for the determination of resin in soaps, with the general result of finding that one and all leave much to be desired in the way of accuracy. Sutherland's process (oxidation by nitric acid) in some instances gave fair results; but this occurs mostly through the balancing of two opposite sources of error, viz., incomplete removal of resin by oxidation, tending to *increase* the percentage of fatty acid found, and oxidation of true fatty acids, tending to *decrease* it. Treatment of aqueous soap solution by various processes intended to throw out of solution true soaps of fatty acids leaving dissolved resinates did not answer at all well in our hands: sometimes fatty soaps were retained in solution, and resinates were often mechanically carried out of solution along with the fatty soaps, and no certainty of complete separation was ever attainable.

On the whole the process recommended by Gladding (CHEMICAL NEWS, April 14, 1882) seemed to give figures most in accordance with the truth, provided the nature of the fatty matters contained in the soap examined were approximately known so as to permit of the application of a correction-factor variable to some extent with this nature. The method consists in separating the fat acids, dissolving about 0·5 grm. in 95 per cent alcohol, neutralising with saturated alcoholic potash, then addding a few additional drops and boiling to saponify any small quantity of glyceride present (through imperfection in manufacture, &c.); after cooling, ether is added to 100 c.c., and finely powdered *neutral* silver nitrate, and the whole well agitated; finally a known fraction of the ethereal solution of silver resinate, &c., is treated with hydrochloric acid, and the liberated resin, &c., weighed after evaporation of the ether. According to Gladding (who, however, only quotes a very small number of test experiments) 100 c.c. of alcoholic ether dissolves 23·5 m.grms. of oleic acid, when "pure fat acid" (mixture of stearic and oleic ?) is thus treated; and this correction-factor he found to be applicable with accuracy when Castille soap, linseed-oil soap, and soaps containing known amounts of resin were examined.

Our experience, however, is that 23·5 m.grms. (representing 4·7 per cent on 0·5 grm. fatty acids and resin) is a correction-factor by no means universally applicable. With pure stearic or oleic acid it is much too large; with acids from castor-oil far too small; with various mixtures it is not far from the truth. Thus the values given in the Table were obtained as the result of a large number of observations which, moreover, did not always show a high degree of concordance, notwithstanding all the care taken to avoid sources of error; partly no doubt this is due to the circumstance that different specimens of oils, &c., were employed in the production of the soaps treated.

The temperature was throughout not far from 18° C., but was not kept absolutely uniform, which circumstance may again partly account for apparent irregularity in the solubility of the silver salts.

Although Gladding's correction of 23·5 m.grms is not strictly applicable in all cases, yet the figures in the Table indicate that it is not far from the truth in at least a number of instances of mixtures likely to occur in actual manufacture: in such cases a tolerably fair approximation to the truth is attainable by assuming that the weight of the resin apparently found in 0·5 grm. of fatty acids should be diminished by some 25 m.grms., or, what is the same thing, that the percentage of resin found in the total fatty acids, &c., is 5 per cent too high. But this correction cannot be regarded as applicable universally.

Nature of fatty matters in soap examined.	Fatty matters dissolved (as silver salt) in 100 c.c. of alcoholic ether. Maximum. M.grms.	Minimum. M grms.	General average. M grms.
Pure stearic acid..	16·0	8·0	11·6
Pure oleic acid	15·0	9·0	12·0
Nearly pure palmitic acid..	30·0	28·0	29·1
Cotton-seed oil	34·0	20·0	26·9
Castor oil	62·0	49·0	53·9
Cocoanut oil (fatty acids dried on water-bath) ..	17·5	12·0	14·8
Cocoanut oil (fatty acids dried over H_2SO_4	23·0	19·0	21·1
Stearic and oleic acids, in nearly equal proportions	22·0	18·0	19·1
Stearic acid and cotton-seed oil, in nearly equal proportions	—	—	25·5
Oleic acid and cotton-seed oil, in nearly equal proportions	—	—	24·5
Stearic acid and cocoanut oil (water-bath), in nearly equal proportions	—	—	23·4
Oleic acid and cocoanut oil (water-bath), in nearly equal proportions	—	—	25·6

A source of error that should not be overlooked is that the concentrated alcoholic potash used as directed by Gladding is liable on keeping to become dark-coloured, and in so doing to contain more or less notable amounts of resinoid matter (from action on the alcohol or impurities contained therein. Several milligrammes of increment in the ether residue may readily be brought about by the use of such potash solution. Another source of error is the decomposition of certain of the insoluble silver salts of fatty acids by light, causing in some instances appreciable amounts of additional matter to become dissolved in the alcoholic ether.

34. "*The Properties of the Nitrobenzalmalonic Acids.*" By Charles M. Stuart, M.A.

On boiling benzalmalonic acid, $C_6H_5{\cdot}CH : C(COOH)_2$, with water, it is resolved partly into benzaldehyde and malonic acid (1), and partly into cinnamic acid and carbon dioxide (2); the three nitro-derivatives behave similarly. the percentage amounts converted in accordance with the first and second modes of change being shown in the accompanying Table (see next column).

Benzalmalonic acid and its para- and meta-nitro-derivatives form additive compounds with bromine and with hydrogen bromide, which are decomposed by water. The ortho-nitro-derivative is converted both by the action of bromine and hydrogen bromide into a condensation product which is not decomposed by water or alcohol. The author suggests that this behaviour may be regarded as an argument in favour of Kekulé's benzene formula.

From cinnamic acid and malonic acid he has obtained a phenyl-butindicarboxylic acid,—

$$C_6H_5{\cdot}CH : CH{\cdot}CH : C(CO_2H)_2;$$

	Boiled for 1 hour. I.	II.	Total.	Boiled for 15 min. I.	II.	Total.
Benzalmalonic acid—						
	85·2	—	—	57·8	1·41	59·2
	85·8	10·8	96·6	58·3	1·25	59·5
	84·4	10·6	95·0	—	—	—
Paranitrobenzalmalonic acid—						
	80·2	14·8	95·0	61·54	3·89	65·4
	82·7	12·4	95·1	62·64	3·77	66·4
Metanitrobenzalmalonic acid—						
	83·1	10·4	93·5	61·3	6·3	67·6
	79·9	14·4	94·3	62·5	5·8	68·3
	79·7	12·6	92·3	—	—	—
Orthonitrobenzalmalonic acid—						
	24·5	5·7	30·2	8·7	1·18	9·88
	23·6	6·5	30·1	8·71	1·25	9·96
	24·4	6·4	30·8	—	—	—

this melts at 208°, but is resolved into CO_2 and cinnamenylacrylic acid.

Salicylic and malonic acids give coumarincarboxylic acid; this melts at 187° without decomposing, but is resolved at a higher temperature into CO_2 and coumarin.

Anniversary Meeting, March 30th, 1886.

The following Officers and Council were elected:—

President—H. Müller, Ph.D., F.R.S.

Vice-Presidents who have filled the Office of President—Sir F. A. Abel, C.B., D.C.L., F.R.S.; Warren De la Rue, D.C.L., F.R.S.; E. Frankland, D.C.L., F.R.S.; J. H. Gilbert, Ph.D., F.R.S.; J. H. Gladstone, Ph.D., F.R.S.; A. W. Hofmann, D.C.L., F.R.S.; W. Odling, M.B., F.R.S.; W. H. Perkin, Ph.D., F.R.S.; Sir Lyon Playfair, Ph.D., K.C.B., F.R.S.; Sir H. E. Roscoe, LL.D., F.R.S.; A. W. Williamson, LL.D., F.R.S.

Vice-Presidents—W. Crookes, F.R.S.; J. Dewar, M.A., F.R.S.; David Howard; G. D. Liveing, M.A., F.R.S.; T. E. Thorpe, Ph.D., F.R.S.; W. A. Tilden, D.Sc., F.R.S.

Secretaries—H. E. Armstrong, Ph.D., F.R.S.; J. Millar Thomson, F.R.S.E.

Foreign Secretary—F. R. Japp. M.A., Ph.D., F.R.S.

Treasurer—W. J. Russell, Ph.D., F.R.S.

Other Members of Council—H. T. Brown; T. Carnelley, D.Sc.; M. Carteighe; Frank Clowes, D.Sc.; A. E. Fletcher; R. J. Friswell; R. Meldola; R. Messel, Ph.D.; J. A. R. Newlands; S. U. Pickering, M.A; W. Ramsay, Ph.D.; Thomas Stevenson, M.D.

NOTICES OF BOOKS.

An Introduction to the Study of Chemistry. By Ira Remsen, Professor of Chemistry in the Johns Hopkins University. New York: Henry Holt and Co.

This work, which decidedly belongs to the superior grade of chemical manuals, is one of the "American Science Series, Briefer Course." In his Preface the author makes some very important remarks on the educational value of chemical study. He holds that in teaching chemistry two mistakes are commonly made. "The first is that of considering the profoundest theories of the science before the student is prepared for them. Hence they make little impression upon his mind, and he only learns *to repeat words about them* without having any real comprehension of them."

We beg to call especial attention to the words which we have italicised. The view is fast gaining ground that not merely in chemistry, but in all departments of the physical and natural sciences, the student should begin not with books, but with the phenomena themselves. When the facts in question have been witnessed and duly

observed,—there is a difference between witnessing and observing,—then, and only then, the words in which such phenomena can be described become clearly and fully intelligible. Text-books are then of use for co-ordinating what has been observed. The student who has read much about chemistry before seeing chemical phenomena seems bewildered when he enters the laboratory. He is not unlikely to ask the teacher "But what am I to observe?" Verbalism seems to have entered into his inmost being.

Prof. R. Galloway pointed out in one of his works the significant fact that in grammar-schools the junior forms seemed better able to observe and understand phenomena than their seniors. The exclusive attention paid to words and abstractions seems to beget in the mind the defect or the vice of inobservance.

"The other mistake," according to Prof. Remsen, "is that of giving directions for experiments without making it clear to the student why they are performed or what they teach. The result is that he sees little or no connection between the subjects treated in the text-book and the things which he works with in the laboratory."

"The first object of a course in science should be to develop a scientific habit of thought." Expanding this proposition of the author's, we may say that the educational object of the study of any science is to cultivate in the student the power of observation. He must learn to see every feature of the phenomena presented to him, and see all this correctly, not mixing up guesses with actual perceptions.

Slovenly, random experimentation is justly denounced as being of little value. Says the author:—"When teachers of chemistry acquire this feeling, and work in this spirit, the educational value of laboratory courses will be greater than it frequently is now. The average playing with test-tubes and precipitates is of questionable benefit. As it has been dignified by the undeserved name of scientific training, and put forward in place of the real thing, many thinking (?) men have been led to question the value of scientific training, and to adhere to the old drill in grammatical forms and mathematical problems."

We should be the last to defend slovenly, random experimentation. At the same time we think that the greatest error in teaching chemistry, in England at least, is one which Prof. Remsen overlooks. This error is to treat chemistry as something to be read about, committed to memory, and ultimately examined in. Says our author:—"A slovenly laboratory course in chemistry is a poor substitute for a well-conducted course in mathematics or languages." In fact the former does not profess to be a substitute for the latter. But neither is the best course in languages, nor even in mathematics, of any avail towards teaching the arts of observation, and of drawing right inductions from the facts observed.

The author has in this work selected for special consideration such substances and such phenomena as he considered best suited for giving an insight into the nature of chemical action.

CHEMICAL NOTICES FROM FOREIGN SOURCES.

NOTE.—All degrees of temperature are Centigrade unless otherwise expressed.

Comptes Rendus Hebdomadaires des Séances, de l' Académie des Sciences. Vol. cii., No. 11, March 15, 1886.

Application of the Diagram of Colours to Experiments made on a Colour-blind Subject.—R. Ferret.—The author concludes that all the colours which a colour-blind eye confounds together have their representative points on one and the same right line parallel to a direction which is constant for this eye. He raises the questions: Is the direction of confusion absolutely the same for all colour-blind persons, making abstraction of the three classes of colour-blindness generally admitted? Is not, in certain persons less thoroughly colour-blind than Maxwell's subject, the direction of confusion not a direction for which the errors committed in the evaluation of the divergences existing between the different colours would pass through a maximum? Is not the infirmity of those rare cases mentioned as recognising among all colours merely the differences of light and shade not the result of two forms of colour-blindness relating to two different directions, so that the places of the colours confounded by these persons are planes mutually parallel.

New Apparatus for the Determination of Oxygenated Water.—Maurice de Thierry.—This apparatus cannot be intelligibly described without the accompanying figure.

Potassium and Sodium Selenides.—O. Fabre.—The author has obtained four sodium selenides, three of which contain respectively 16, 9, and 5 mols. of water, while the fourth is anhydrous. The potassium selenides are less stable; the author has here also obtained and examined three hydrates containing 19, 14, and 9 mols. of water and an anhydrous form. The method followed has been to pass gaseous hydroselenic acid into strong alkaline solutions. To obtain pure products it is necessary to operate in an atmosphere of nitrogen.

Formation and Dissociation of Barium and Strontium Manganates.—The decomposition of the alkaline-earthy manganates in an oxidising fire seems to traverse a cycle. At a dull red it is almost null; at the heat of a Bunsen burner it becomes very perceptible and the manganite formed corresponds to the type MnO_2RO. At a temperature between the melting-points of silver and copper the dissociation reaches a maximum corresponding to the formation of a dimanganite, $2MnO_2,RO$. At a stronger heat, between the melting-points of copper and gold, the manganite re-appears, whilst at a still higher temperature (1500° for the barium compound and 1600° for strontium) manganate is again produced.

Variations of Solubility of Certain Chlorides in Presence of Hydrochloric Acid.—R. Engel.—The author proposes the following approximate generalisation: the solubility of the chlorides which hydrochloric acid precipitates from their solutions in water diminishes in presence of this acid by a quantity corresponding sensibly to an equivalent of the chloride for each additional equivalent of hydrochloric acid.

Separation and Determination of Copper, Cadmium, Zinc, Nickel, &c.—Ad. Carnot.—This paper will be inserted in full.

Existence of the Elements of Milk-Sugar in Plants.—A. Müntz.—The author refers to the constitutional difference between milk-sugar and glucose. He finds that galactose, hitherto regarded as absent in plants, is chemically and physically identical with the arabinose of true gum arabic. Hence he considers that the latter name ought to be cancelled, and hence both the proximate elements of milk-sugar exist in abundance in the vegetable world.

Splitting up of the Sodium-Ammonium and Sodium-Potassium Racemates.—G. Wyrouboff.—A critique of M. Bichat's paper communicated to the Academy on Feb. 22nd. The writer concludes that the inorganic germs which M. Bichat supposes as intervening play no part other than that of desupersaturating solutions capable of becoming supersaturated; their action is null when supersaturation is excluded. In the case of the sodium potassium salt we may, according to the temperature, cause by the introduction of a crystal of the corresponding salt the crystallisation either of a racemate or a tartrate. The splitting up of the sodium-ammonium and

he sodium-potassium racemates is therefore a simple question of solubility, which itself is again a function of the temperature.

On the Earth Yα.—W. Crookes.—See CHEMICAL NEWS, vol. liii., p. 133.

On the Mosandra of Lawrence Smith.—Lecoq de Boisbaudran.—Dr. Marvin, of Louisville, has supplied the author with a specimen of an earth from the laboratory of the late L. Smith and considered as being impure mosandra. It contains much didymium and samarium; but L. Smith observed absorption spectra carefully and described the salts of mosandra as not giving any. It is therefore evident that the specimen obtained from Dr. Marvin was at the most mosandra very imperfectly purified. M. Lecoq de Boisbaudran fractionated this earth with ammonia as far as the small bulk of the specimen permitted; almost all the didymium and the greater part of the samarium were thus eliminated. The residue gave the electric spectrum of Yα very brilliantly, and the author therefore suspected that this latter body might perhaps represent the purified matter described by Smith. However, as M. de Marignac very judiciously pointed out, L. Smith described his mosandra as an oxide deeply tinged with an orange-yellow, whilst the Yα prepared by M. de Marignac is very faintly coloured and would probably be white if absolutely pure. The earth which M. de Boisbaudran has obtained from crude mosandra by eliminating didymium and samarium is of a deep orange yellow and gives the fluorescences $Z\beta$ and $Z\alpha$, the former predominating. Hence, and in accordance with the opinion of M. de Marignac, it appears very probable that the mosandra of L. Smith is essentially a mixture of Yα and of terbia, the latter probably in excess.

MISCELLANEOUS.

The Chemical Laboratory of Wiesbaden.—The chemical laboratory of Geh. Hofrath Prof. Dr. A. Fresenius, at Wiesbaden, enjoys a very large attendance. In the winter term, 1885—86, there were 90 students on the books. Of these, 58 were from Germany, 6 from Austro-Hungary, 6 from North America, 5 from England, 5 from Russia, 3 from France, 2 from Switzerland, 2 from Holland, 1 from Luxemburg, 1 from Sweden, and 1 from Norway. Besides the director, Geh. Hofrath Prof. Dr. R. Fresenius, there are engaged as teachers in the establishment Prof. Dr. H. Fresenius, Dr. E. Borgmann, Dr. W. Fresenius, Dr. E. Hintz, Dr. med. F. Hueppe, and Architect Brahm. The assistants in the instruction laboratory were two in number, in the private laboratory twelve, and in the Versuchsstation three. During the last term, besides the scientific researches, a great number of analyses were undertaken in the different departments of the laboratory and the Versuchsstation on behalf of manufacture, trade, mining, agriculture, and hygiene.

NOTES AND QUERIES.

*** Our Notes and Queries column was opened for the purpose of giving and obtaining information likely to be of use to our readers generally. We cannot undertake to let this column be the means of transmitting merely private information, or such trade notices as should legitimately come in the advertising columns.

Vulcanised India-rubber.—Can anyone inform me where I may obtain information as to the various substitutes for caoutchouc, and means of detection of same when vulcanised and mixed with various mineral substances, such as oxide of zinc, chalk, steatite, &c.? Also if there is any solvent known to dissolve vulcanised caoutchouc.—S. S.

Ear-rings of Lead.—Has lead any rapid chemical healing power, for in Russia the ears of ladies are pierced with rings of that metal? And will any of your readers kindly supply the reason why lead rings obtain such popularity in Russian fashionable society? Not being a chemist I am obliged to seek the kind assistance of your journal through the "Notes and Queries" column.—W. T.

MEETINGS FOR THE WEEK.

MONDAY, 5th.—Medical, 8.30.
—— Society of Chemical Industry, 8. "The Principles and Methods of Testing Cementing Materials," by Prof. Unwin, M.I.C.E.
—— Society of Arts, 8. (Cantor Lectures). "The Arts of Tapestry-Making and Embroidery," by Alan S. Cole.
TUESDAY, 6th.—Institution of Civil Engineers, 8.
—— Royal Institution, 3. "The Function of Circulation," by Professor Arthur Gamgee, M.D., F.R.S.
—— Pathological, 8.30.
WEDNESDAY, 7th.—Society of Arts, 8. "Preparation of Drawings for Photographic Reproduction," by J. S. Hodson.
—— Geological, 8.
THURSDAY, 8th.—Royal, 4.30.
—— Royal Institution, 3. "Electro-Chemistry," by Prof. Dewar, F.R.S.
—— Society of Arts, 8. "Asbestos and its Applications," by James Boyd.
—— Mathematical, 8.
FRIDAY, 9th.—Royal Institution, 9. "New Applications of the Mechanical Properties of Cork to the Arts," by W. Anderson, M.Inst.C.E.
—— Quekett Club, 8.
—— Astronomical, 8.
SATURDAY, 10th.—Royal Institution, 3. "Fuel and Smoke," by Prof. O. Lodge, D.Sc.
—— Society of Arts, 3. "Electricity," by Professor George Forbes, M.A., F.R.S.E.
—— Physical, 3. "On the Causes of the Diurnal Changes of Terrestrial Magnetism," by Professor Balfour Stewart, F.R.S.

SUGGESTIONS AS TO THE CAUSE OF THE PERIODIC LAW, AND THE NATURE OF THE CHEMICAL ELEMENTS.*

By THOS. CARNELLEY, D.Sc.,
Professor of Chemistry in University College, Dundee.

(Continued from p. 159.)

Now what conclusions are to be drawn from such facts as those represented in the above tables? In addition to the general conclusion *that the melting- and boiling-points of both organic and inorganic compounds obey the same rules*, we may also infer—

That the elements as a whole are analogous to the hydrocarbon radicles (see Tables IX. and XI.), *having a similar function in their several compounds, and most probably a somewhat similar chemical constitution*, or, shortly, *they are analogous in both form and function.*

This analogy will be best exhibited in Tables VIII. and IX.

Taking first the points of *resemblance* :—

1. The properties of the elements and their compounds and those of the hydrocarbon radicles and their compounds are strictly periodic, a period in each case consisting (if we neglect group VIII.) of seven members.

2. As shown above the melting and boiling-points of both the halogen and alkyl compounds of either the elements of Table VIII. or of the hydrocarbon radicles in Table IX. follow the same rules; that is to say, if we make any systematic arrangement of the compounds of the Elements in Table VIII., and a corresponding systematic arrangement of the compounds of the radicles in Table IX., then the numerical order of the physical properties (as represented by the melting and boiling-points) will be the same in the two cases.

3. The atomicity in each series, in the case of both elements and hydrocarbon radicles, increases up to the middle group and then diminishes or increases up to the 7th or last group (*cf.* differences *infra*).

4. The compounds of the elements are strictly analogous in form to those of the hydrocarbon radicles, as witness the following examples :—(See next page.)

5. Mendeljeff in his original paper on the Periodic Law (*Annalen*, Suppl., viii., 133) draws attention to the fact that the elements of the first or Li-series, and also part of the Na-series, are to some extent different from those of the other series, and the elements comprising them are hence termed by him "typical elements." The exceptional character of these series he compares with the usual and well-known exceptional character of the

The hydrocarbon radicles in the table may be represented by the general formula $C_n H_{2n+(2-x)}$, in which n = the series, and $x=(8-a)$, a being the group to which the element belongs.

It will be seen at a glance that there is a great resemblance between the two tables both in structure and arrangement; but there are nevertheless certain points of difference which it will be well to mention in detail along with the points of resemblance.

first and second members of a homologous series of organic chemistry.*

* A Paper read before the British Association, Aberdeen Meeting.

* Compare Perkin's paper on "Magnetic Rotation" (*Jour. Chem. Soc. Trans.*, 1884, p. 552; Chem. News., xlix., 285), in which he says "that any body to be the first member of a homologous series must contain the CH_3-group, because it is by the introduction of additional members of this group that we form the series. Thus, propionic acid should be the first member of the homologous series of fatty acids. Formic and acetic acids do not contain the CH_3-group, and they are well known to possess properties which are not altogether comparable with those of the other fatty acids."

* Most probably the series of hydrocarbon radicles, as represented here and in Table IX., should be inverted so that Groups VII., VI., and V. would become I., II., and III., respectively. With regard to this point, *vide infra*. If such an inverted arrangement be adopted, then glycerol, propylene glycol, and propyl alcohol would be represented as analogous to Al, Mg, and Na hydrates respectively, an analogy which would be truer than the one shown here.

This therefore furnishes another point of analogy between the elements of Table VIII. and the radicles of Table IX.

6. The numerous cases in which, in many reactions, the hydrocarbon radicles act in a manner strictly analogous to that of the elements are too well known to need further particularisation in detail.

Let us now consider the points in which the elements of Table VIII. differ from the radicles of Table IX.

1. Though it is true that both the elements and the hydrocarbon radicles are strictly periodic in their properties and in those of their compounds, and that the periods are of the same length, consisting of seven members in each case, yet the nature of the periodicity (at least in so far as the melting- and boiling-points are concerned) is not exactly the same in both. In the case of the halides of the elements the melting- and boiling-points *diminish as we pass from the first to the seventh group*, whereas in the case of both the halides and alkides of the hydrocarbon radicles these properties *increase up to the fourth group, and then diminish to the seventh*; whilst the alkides of the elements partake of the features of each, since they increase up to the third and then diminish to the seventh group. The alteration in the order of size of these physical properties is therefore the same in all cases from the fourth to the seventh group inclusive, but different from the first to the third group. This difference and resemblance is shown in the following Table, in which the numbers referring to the halides have been obtained by adding the boiling-points (or melting-points) of the chlorides of the corresponding members of each series together, the same operation being repeated with the bromides and iodides. The sum of the boiling-points (or melting-points) of the chlorides is then added to that of the bromides and iodides, and the mean taken. A similar operation gives the average mean boiling-points for the alkides (methides, ethides, propides). As there are five series under consideration, each number is the mean of $5 \times 3 = 15$ separate data: whilst in the case of the halides of the elements each number is the mean of 18 data, since in this case we are dealing with six series.

The above facts are rendered still more evident by Diagrams I., II., and III., of which I. shows the *average mean* curves of (1) the melting-points of the halides (Cl, Br, and I) of the elements; (2) the boiling-points of the alkides (Me, Et, Pr) of the elements; (3) the boiling-points of the halides (Cl, Br, I) of the hydrocarbon radicles; (4) the boiling-points of the alkides (methides only) of the same. The curve is constructed by taking the average mean temperatures of melting or boiling (see Table X.) as ordinates, and the atomicity of the elements or hydrocarbon radicles as abscissæ.

Diagrams II. and III. represent the same facts, but in greater detail. Diagram II. gives the *mean* curves of—(1) the alkides (Me, Et, Pr) of the elements*; (2) the halides (Cl, Br, I) of the hydrocarbon radicles; (3) the

* That is, of elements of Series 1, 2. 4, 6, and 10, these being the only elements which combine with alcohol radicles.

alkides (methides only) of ditto. Diagram III.* gives the mean curve of the melting-points of the chlorides, bromides, and iodides of the elements.

A very marked feature in the curves of the halides of the elements, as shown by Diagram III., and more especially by Diagram I., is the sudden and great rise in melting-point (the same also holds true for the boiling-point) which occurs at the positive end of each series as we pass from triad to dyad, and thence to monad, metals. What may be the cause of this it is very difficult to say. The only explanation which occurs to me is that it may possibly be due to polymerisation, in which case the molecules of the halides of the alkaline and alkaline-earth metals, also of Ag, Cu, Zn, Cd, &c., would not be really represented by their ordinary simple formulæ, but by some multiple thereof,—*e.g.*, $(NaCl)_n$, $(KBr)_n$, &c. In this connection note the abnormally high boiling-point of C_2Cl_2 in the second series of the chlorides of the hydrocarbon radicles, and already referred to in my first paper, and shown in the diagram accompanying that paper. This compound stands on a part of the curve corresponding to that occupied by $MgCl_2$ in the curve of the halides of the elements, and its high boiling-point is undoubtedly due to its being a polymer $(C_2Cl_2)_n$. For a similar reason may not the abnormally high melting-point of $MgCl_2$ be due to its being really a polymer $(MgCl_2)_n$? This explanation, however, is not altogether satisfactory, for C_2Cl_2 is a non-saturated compound, and could hence easily undergo polymerisation, whilst $MgCl_2$ is, so far as known, a saturated compound.

2. A second point in which the elements of Table VIII. differ from the hydrocarbon radicles of Table IX. is that the groups in the former, though frequently, are not always numerically homologous, whereas in the latter case they are strictly so throughout. (If, however, the arrangement of the hydrocarbon radicles in Table XI. be adopted, this statement would require some modification.

3. In the case of the elements each group is divisible into two sub-groups, because, as pointed out by Mendeljeff, it is only the alternate members of a group which are strictly comparable with one another. The several series of elements in Table VIII. are therefore printed alternately in thin and thick type.

(To be continued).

NOTE ON THE REACTION OF TIN WITH SULPHURIC AND NITRIC ACIDS.

By H. BASSETT.

THE formation of stannic sulphate by the action of sulphuric acid alone on tin requires, as is well known, a high temperature: the addition of a small quantity of nitric acid, which readily supplies the necessary oxygen, greatly facilitates the action, and was long ago applied in the manufacture of the ornamental articles of tin-plate known as "Moirée metallique," the mixed acids dissolving a film of tin from the surface and exposing the crystalline structure of the metal.

A mixture of 1 part sulphuric acid, 2 parts nitric acid, and 3 parts water, all by measure, has a remarkable solvent action on tin in the cold. A solid lump of the metal weighing 10 grms. dissolves completely in a few hours in 50 c.c. of this mixture, the containing vessel being immersed in cold water. Under these circumstances no red fumes are given off, but a steady evolution of nearly pure nitrous oxide goes on the whole time. The resulting solution of stannic sulphate is quite clear unless the temperature has been allowed to rise, in which case it becomes beautifully opalescent, and if heated in the water-oven for an hour it becomes nearly solid and opaque.

On pouring the solution (still containing some nitric acid) into boiling water, the tin is completely precipitated in the form of gelatinous metastannic acid, which, after thorough washing with boiling water, dries up in the water-oven into semi-transparent lumps.

Attempts to utilise this reaction for the solution and analysis of tin alloys have not proved satisfactory: in presence of some metals a small quantity of tin appears to escape precipitation, while others show more or less tendency to go down with the precipitate.

ON THE SEPARATION AND THE DETERMINATION OF COPPER, CADMIUM, ZINC, NICKEL, &c.

By A. CARNOT.

COPPER, cadmium, zinc, nickel, cobalt, manganese, and iron may occur in certain ores and in a number of industrial alloys. Their successive separation in analysis presents great practical differences by reason of the analogous properties of their salts.

The methods of separation about to be explained are principally founded upon the use of sodium or ammonium hyposulphite, and on that of sulphuretted hydrogen in solutions successively acidified by sulphuric or hydrochloric acid, by oxalic acid, and, lastly, by acetic acid.

The precipitation of copper by sodium hyposulphite in a boiling sulphuric solution was first recommended by Flajolot as a means of separating it from zinc and nickel. Much more recently Vortmann found that the same reagent effects the separation of copper and cadmium with great exactitude.

The author has satisfied himself of this fact, under different conditions which appeared preferable and making use of ammonium hyposulphite, which in comparison with the sodium salt has the advantage of not introducing a fixed alkali.

The solution containing copper, cadmium, and other metals diluted to 200 or 300 c.c., is acidified with 10 to 15 c.c. hydrochloric acid, heated to boiling and mixed with hyposulphite, added in successive portions until the precipitate, instead of becoming at once a deep brown from the formation of copper sulphide, remains for some time white and milky, from the liberation of sulphur. When the liquid is cleared by boiling, the precipitate is collected on a filter. It contains all the copper as Cu_2S. It is dried, the filter is burnt, mixed with powdered sulphur, and ignited in a small crucible traversed by a current of dry hydrogen (H. Rose's apparatus). The sulphide is weighed, containing 79·87 of copper. The cadmium may be precipitated by sulphuretted hydrogen or ammonium hydrosulphate.

The separation of cadmium and zinc is effected by an analogous operation, care being taken that the solution contains no other free acid save oxalic acid, and that the precipitated sulphides are not mixed with oxalates.

It must be observed, to this end, that the zinc is precipitated as simple oxalate, scarcely soluble in ammonium chloride, whilst the cadmium forms in presence of ammonia a double oxalate, easily soluble in the same reagent. If we add beforehand 10 parts of ammonium chloride to 1 part of metal we may completely prevent the precipitation of cadmium by oxalic acid or ammonium oxalate. The operation may be thus conducted whatever are the relative proportions of zinc and cadmium.

The solution, supposed to be acid and but little diluted, is exactly neutralised with ammonia. An excess of salammoniac is then added, and about 2 grms. oxalic acid in solution, and the whole is boiled for some minutes. If the zinc is in notable quantity, and forms a crystalline

* The separate curves for the chlorides, bromides, and iodides respectively of the elements have already been given in an earlier paper (*Phil. Mag.*, v., 18, 1).

deposit of oxalate, it is separated by decantation and washed with a hot solution of ammonium chloride. If it is in very small quantity there may be no deposit to separate. The solution containing all the cadmium and a little zinc, diluted to 200 or 250 c.c. and raised to a boil, ought not to give any further precipitate. There is then added at once or in several portions ammonium hyposulphite, acidifying afresh, if needful, with oxalic acid, and it is kept at a boil as long as the orange precipitate of cadmium sulphide appears to increase.

Each fresh addition of the reagent gives rise at first to a milky white precipitate of sulphur, which gradually turns orange. We ascertain that the precipitation is complete by decanting a portion of the liquid through a filter, adding a little more hyposulphite and oxalic acid, and boiling again. It ought to give merely a white turbidity, and finally a light yellow deposit of sulphur.

The sulphide of cadmium thus formed is dense, not bulky, easy to wash by decantation, and is totally free from zinc.

It is re-dissolved in dilute boiling nitric acid, the solution is evaporated to dryness in a small tared capsule, re-dissolved in a little dilute sulphuric acid, evaporated again, calcined below a red-heat, and weighed as cadmium sulphate containing 53·84 per cent of metal.

The zinc is found entirely in the oxalic solution and in the first crystalline precipitate. The latter is calcined separately, and converted into zinc oxide. The zinc in the solution is precipitated by a current of sulphuretted hydrogen. The whiteness of the precipitate shows that the liquid did not contain a trace of cadmium. It is filtered, dried, the filter burnt, and the whole ignited in a small Rose's crucible traversed by a current of dry hydrogen sulphide. The zinc sulphide, the sulphate which may have been formed during the combustion of the filter, and the oxide derived from the decomposition of the oxalate, are all brought to the state of sulphide containing 67·13 per cent of zinc.—*Comptes Rendus* (cii., p. 621).

THE DIASTATIC ACTION OF SALIVA, AS MODIFIED BY VARIOUS CONDITIONS, STUDIED QUANTITATIVELY.*

By R. H. CHITTENDEN and HERBERT E. SMITH.

(Concluded from p. 163).

b. Influence of Free Acid.

In view of the fact that some time ago one of us† was of the opinion that small percentages of acid‡ tended to increase the diastatic action of saliva, it was of especial interest now to ascertain definitely whether free acid when present in small percentages does invariably retard diastatic action. Langley and Eves state that "although saliva neutralised to litmus sometimes shows an increase of action on the addition of 0·0005 to 0·001 per cent HCl; yet if the proteids of the saliva be saturated with acid, there is a diminution of its amylolytic action, although no free acid is present in the saliva." This we cannot regard as correct without qualification, since our experiments appear to show that saliva with its proteid matter saturated with acid has a greater diastatic action in a given time than saliva simply neutralised, provided the percentage of acid-saturated proteids is not too large. The same investigators further state "that 0·0015 per cent HCl distinctly diminishes the amylolytic action of ptyalin," and "since 0·0015 per cent HCl increases amylolytic action it seems very unlikely that 0·005 per cent should increase it;" but as Langley and Eves, in studying the influence of free acid, apparently used diluted neutralised saliva, in which the proteids present were not combined with acid, depending simply upon dilution to avoid the influence of these bodies, it seems to us a little uncertain whether their results are strictly accurate on this point, since saliva even very much diluted does contain some proteid matter. They, however, state in this connection that "we have often found that solutions which we have thought carefully neutralised have been increased in action by the presence of still smaller percentages of acid, viz :— 0·0005 to 0 0010 per cent." Here, however, so far as their results show, the observed increase of activity may have been due to the small amount of acid-proteid matter present, certainly could not have been due wholly to free acid.

We have tried a large number of experiments on this point in a variety of ways, all of which tend to show that a very small trace of free acid, when the amount of acid-proteids is not large, does, seemingly, slightly increase the diastatic action of the ferment. It is, perhaps, questionable, however, whether in the use of such small percentages of acid, the results are to be strictly depended upon. The presence of a small amount of phosphate in the starch, or a trace of alkali, not to be detected by litmus, might easily neutralise the small amount of acid added. Again, non-saturation of the proteids to only a very slight extent might effect the result. We subjoin two or three of our experiments.

SERIES XX.

20 c.c. filtered saliva were neutralised and then sufficient acid added to combine with the proteids present; the mixture then diluted to 100 c.c. The solution contained 0·0114 grm. combined HCl, but no free acid. (A).

20 c.c. of the same filtered saliva neutralised, and the proteids just saturated with acid. 3·1 c.c. 0·1 per cent HCl were then added and the mixture diluted to 100 c.c. The solution contained 0·0114 grm. combined HCl, and in addition 0·0031 grm. free HCl. The solution gave a distinct violet with tropæolin oo. (B).

Digestions were made, using 1 grm. starch in a volume of 100 c.c. Time, thirty minutes. Following are the results.

	A.		B.	
Amount diluted saliva. C.c.	Wt. Cu in one-eighth. Grm.	Total amt. sugar. Grm.	Wt. Cu in one-eighth. Grm.	Total amt. sugar. Grm.
20	0·0988	0·4024	0·0972	0·3960
10	0·0917	0·3736	0·0921	0·3752
5	0·0826	0·3368	0·0861	0·3512

Amount diluted saliva.	Starch converted. A.	Starch converted. B.	Free HCl in B.
20 c.c.	36·23 p.c.	35·65 p.c.	0·00062 p.c.
10	33·53	33·78	0·00031
5	30·32	31·62	0·00015

Here there can be no question but that there was free acid in B. The saliva gave a distinct reaction with tropæolin oo and the starch used was apparently neutral. In this instance 0·0006 per cent free acid slightly diminished the diastatic action, while 0·0003 per cent slightly increased it.

A second experiment of like nature gave the following results :—

SERIES XXI.

20 c.c. filtered saliva were neutralised and the proteids exactly saturated with HCl, then diluted to 100 c.c. The solution contained 0·0073 per cent combined HCl, but no free acid. (A).

20 c.c. of the same saliva neutralised and the proteids saturated by the addition of the same amount of acid as in A; 1·2 c.c. 0·1 per cent HCl were then added, so that a distinct tropæolin reaction could be obtained in the 41 c.c. of fluid. The fluid was diluted to 100 c.c. and then contained 0·0012 per cent free HCl. (B).

20 c.c. of the same saliva neutralised and the proteids

* From *Transactions Connecticut Academy*, vol. vi., March, 1886.

† Chittenden and Griswold, *loc. cit.*

‡ Considered as 0·005 per cent, although we now know the above figure could not represent free acid, owing to the proteid matter of the saliva.

exactly saturated with acid; then enough more acid added to give a distinct tropæolin reaction, after which the solution was diluted to 100 c.c. The 100 c.c. of fluid contained exactly 0·003 grm. HCl. (C).

A drop of the latter fluid on being tested gave a distinct violet with tropæolin 00.

Following are the results of digestions made with the oregoing solutions of saliva.

Amount of diluted saliva.	Starch converted. A.	B.	C.
20 c.c.	35·65 p.c.	35·58 p.c.	35·36 p.c.
10	33·71	33·27	34·14
5	28·81	29·53	30·32

Here it is seen, as before, that the smaller percentages of free acid arising from the use of 5 and 10 c.c. of saliva, show a distinctly increased diastatic activity, while with 20 c.c. the results are very nearly identical; too large an amount of free acid to increase the action and yet not enough to materially diminish it.

We next tried the influence of *increased* percentages of free acid on the action of ptyalin.

Series XXII.

30 c.c. filtered saliva were neutralised and the proteids just saturated with acid, then diluted to 150 c.c.; 10 c.c. of this diluted saliva equal to 2 c.c. of the original saliva were used in each digestion. Following are the results, after warming with starch at 40° C. for thirty minutes in the presence of the percentages of free acid specified. The acid solutions were mixed with the starch previous to the addition of the saliva.

Per cent free acid.	Wt. Cu in one-eighth.	Total amount sugar.	Starch converted.
0	0·0919 grm.	0·3744 grm.	33·71 p. c.
0·0006	0·0924	0·3768	33·92
0·0010	0·0773	0·3152	28·37
0·0020	0·0166	0·0744	6·69
0·0030	trace		

Here a slight increase is noticed with 0·0006 per cent followed at 0·002 per cent by a rapid fall in diastatic action.

With stronger solutions of ptyalin like results were obtained as follows:—

Series XXIII.

Filtered saliva was neutralised and the proteids just saturated with HCl. An amount of this fluid equivalent to 5 c.c. of the original saliva was used in each digestion. In this amount there was present 0·00266 grm. combined HCl, but no free acid whatever.

Following are the results of digestions with this saliva in the presence of the percentages of free acid specified.

Per cent free acid.	Wt. Cu in one-eighth.	Total amount sugar.	Starch converted.
0	0·0956 grm.	0·3896 grm.	35·07 p. c.
0·0005	0·0966	0·3936	35·43
0·0010	0·0867	0·3536	31·80
0·0020	0·0162	0·0728	6·55
0·0030	trace		

Increasing now the amount of saliva still further, so that the percentage of combined acid reaches a point where its retarding influence begins to be felt, the presence of the smallest amount of free acid then causes at once a dedided decrease in diastatic action. Thus, using the same saliva as was employed in the preceding series, only in such quantity 20 c.c. of original saliva were present in each digestive mixture, it was found that the free acid produced a much greater retarding effect than before. The percentage of combined hydrochloric acid, in the form of acid-proteids contained in each digestive mixture was 0·01064 per cent. Following are the results of the diastatic action.

Per cent free acid.	Wt. Cu in one-eighth.	Total amount sugar.	Starch converted.
0	0·0972 grm.	0·3960 grm.	35·65 p.c.
0·0005	0·0830	0·3384	30·46
0·0010	0·0410	0·1712	15·41
0·0020	0·0061	0·0328	2·95
0·0030	trace		

This result accords with the statement made by Langley and Eves, "that if the proteids of saliva be saturated with acid there is a diminution of its amylolytic action, although no free acid is present in the saliva. This diminution is made more marked by the addition of the smallest quantity of hydrochloric acid." The above quantitative results plainly testify to the accuracy of the latter part of their statement. As to the action of the acid-saturated proteids that is wholly dependent upon the percentage present.

c. Destructive Action of Free Acid.

It has been clearly shown* that acid approximating to the strength of the acid of the gastric juice has a destructive action on the salivary ferment. Smaller percentages of acid have a like destructive action. It has at the same time been shown that the presence of very much smaller percentages of free acid stops the amylolytic action of the ferment. Is this stopping of the amylolytic action in every case due to destruction of the ferment, or simply to the retarding action of its presence? Langley, by using an aqueous extract of the parotid of rabbits, with but little proteid matter, concluded that the presence of 0·014 per cent hydrochloric acid is sufficient to destroy all but the merest trace of ferment in five minutes at 39° C. This before the action of acid-proteids was known. Chittenden and Ely, by experimenting with human saliva, came to the conclusion "that there may be in the presence of a *very dilute* acid a simple stopping of the diastatic action, without destruction of the ferment;" in other words, the retarding influence of very small percentages of free acid is not necessarily due to destruction of the ferment. Langley and Eves, criticising this conclusion, state "that since Chittenden and Ely apparently used unneutralised saliva, and took no account of the proteids present, it seems to us probable that not only was there no free hydrochloric acid in their experiments, but that even the proteids were not saturated with acid." In the article to which they refer it is, however, explicitly stated in a footnote† that the saliva was neutralised, and then an amount of acid added to equal 0·025 per cent. Unfortunately we did not know then of the action of acid on the proteids of the saliva; consequently the above percentage must have been mainly in the form of combined acid. Still the smaller percentages of free acid do not show great destructive action; their power of retarding the action of the ferment is out of all proportion to their power of destruction. Amylolytic action is almost entirely stopped by the presence of 0·002 per cent free hydrochloric acid, but warming saliva at 40° C. with 0·002 or even 0·005 per cent hydrochloric acid for thirty minutes causes little if any destruction of the ferment. On neutralisation, diastatic action goes on as vigorously as ever.

This is well illustrated by the following experiments:—

Series XXIV.

20 c.c. of filtered saliva were neutralised, the proteids just saturated with acid, and the mixture diluted to 100 c.c. The solution contained 0·007 per cent combined HCl.

10 c.c. of this diluted saliva were warmed with the specified percentages of acid for a definite time, then neutralising and equalising mixtures were added, and the diastatic action determined.

* Chittenden and Griswold, *loc. cit.*; Chittenden and Ely, *loc. cit.* Langley, *loc. cit.*

† *Amer. Chem. Jour.*, vol. iv., p. 119.

Following are the results:—

Length of time at 40° C.	Per cent of free HCl.	Starch converted.
30 minutes	0	32·63 per cent.
30	0·001	34·08
30	0·002	31·38
60	0·002	32·48
30	0·005	31·27
30	0·010	4·60
30	0·030	Complete destruction.

Although the results are for some reason a little irregular it is very evident that up to 0·005 per cent of free acid there is, under these conditions, no particular destruction of the ferment. With 0·010 per cent, on the other hand, the destruction is very great.

As to the bearing which these results have on the possible amylolytic action of saliva in the stomach, it is plain that when the fluids of the stomach acquire an acid reaction, due to the presence of free hydrochloric acid, ptyalin will soon be destroyed. In the first stage of digestion, however, when there is no free acid, the conversion of starch into sugar can undoubtedly go on, and at this stage of the process the proteid matter present may act as a shield to protect the ptyalin, and at the same time to stimulate it in its action; but as the acid-proteids increase in amount, and come nearer and nearer to their saturation point, it is possible that diastatic action may entirely stop even before free acid makes its appearance. Certainly all salivary ptyalin must ultimately be destroyed in the stomach.

General Conclusions.

1. The diastatic action of saliva can be taken as a definite measure of the amount of ferment present only when the dilution of the saliva in the digestive mixture is as 1:50 or 100. The limit of dilution at which decisive diastatic action will manifest itself with formation of reducing bodies is 1:2000—3000, under the conditions previously given.

2. The diastatic action of neutralised saliva is greater than that of normally alkaline saliva. The difference is particularly noticeable where the dilution is as 1:50 or 100, and is apparently out of all proportion to the amount of alkalinity.

3. Sodium carbonate retards the diastatic action of ptyalin in proportion to the amount of alkaline carbonate present. The percentage of alkaline carbonate, however, which hinders diastatic action can be designated only for definite mixtures, and not in a general sense, being dependent upon the dilution of the saliva and the consequent change in percentage of proteid matter.

4. The destructive action of sodium carbonate is modified materially by the dilution of the saliva, becoming greater the more the fluid is diluted. This result is due not to simple dilution, but doubtless to the diminished amount of proteids.

5. Neutral peptone has a direct stimulating effect on the diastatic action of neutral saliva.

6. The presence of small percentages of neutral peptone tends to raise the diastatic action of normally alkaline saliva to a point even beyond the action of the neutralised fluid; due in part doubtless to a loose combination of the alkali with the proteid matter, and also to a direct stimulation of the ferment. Likewise peptone tends to diminish in a similar manner the retarding action of the various percentages of sodium carbonate. To accomplish this, however, the amount of peptone must be proportionate to the percentage of alkaline carbonate.

7. Peptone tends to prevent the destructive action of dilute sodium carbonate on salivary ptyalin, thus giving proof of the probable formation of an alkaline-proteid body.

8. Saliva with its proteid matter saturated with acid appears to have a greater diastatic action than when simply neutralised, except when the acid-proteids thus formed are above a certain percentage. Small percentages of peptone saturated with acid similarly increase the diastatic action of neutralised saliva up to a certain point. Increasing the percentage of acid-proteids finally causes a diminution of diastatic activity.

9. The retarding influence of acid-proteids is out of all proportion to their power of destruction. Large percentages, however, of acid-proteids may cause almost complete destruction of the ferment.

10. The most favourable condition for the diastatic action of ptyalin, under most circumstances, appears to be a neutral condition of the fluid, together with the presence of more or less proteid matter. The addition of very small amounts of hydrochloric acid, however, to *dilute* solutions of saliva, giving thereby a *small percentage* of acid-proteids, appears to still further increase diastatic action. Under *such conditions* a minute trace of free acid appears to still further increase the action.

11. 0·003 per cent free hydrochloric acid almost completely stops the amylolytic action of ptyalin. The larger the amount of saturated proteids the more pronounced becomes the retarding action of free acids.

12. The retarding effects of the smaller percentages of free acid are not due wholly to destruction of the ferment. Pronounced destruction takes place with 0·005 to 0·010 per cent free hydrochloric acid.

13. Proteid matter, in influencing the diastatic activity of salivary ptyalin, acts not only by combining with acids and alkalies, but apparently also by direct stimulation of the ferment.

Sheffield Laboratory of Yale Cottage.

ANALYSES OF COMMERCIAL FERTILISERS.*

(Continued from p. 150.)

Volumetric Estimation of Potash.

F. MOORE† has proposed to estimate the potash in K_2PtCl_6 by fusing with double its weight of sodium oxalate, dissolving the mass in water, and estimating the Cl volumetrically in the solution.

Koninck‡ has given a method of obtaining the whole of the chloride in a form easy of titration. He treats the hot aqueous solution of the K_2PtCl_6 with metallic magnesium. The platinum is precipitated with formation of magnesium oxide and escape of hydrogen. Titration is accomplished with silver nitrate, using potassium chromate as indicator.

M. Dubernard§ has lately proposed a new process for volumetrically estimating potash.

This method consists in precipitating the potash salt acidified by nitric acid with titrated solution of chloroplatinate of sodium and afterwards estimating the excess of this solution by a solution of nitrate of silver with previous reduction of the platinum salt remaining in solution by zinc. By reason of the favourable double decomposition secured by the employment of the chloroplatinate of sodium, the method is applicable to all potassium compounds—carbonates, sulphates, chlorides, nitrates, phosphates, &c. A solution of 12 to 15 per cent of chloroplatinate of sodium in alcohol diluted with an equal volume of water is employed. On the other hand, a solution of silver containing from 12 to 15 grms. of the nitrate per litre is used. Following is the method of titrating these solutions:—

Of the solution of platinum 10 c.c. are taken in a flask holding 100 c.c.; to this is added a small portion of zinc powder, and the solution is boiled for a minute; all the

* From the *Proceedings* of the Second Annual Meeting of the Association of Official Agricultural Chemists, at Washington, D.C., September 1, 1885. Edited by Charles W. Dabney, Jun., Ph.D., North Carolina Agricultural Experiment Station, Secretary.

† *Zeit. Anal. Chem.*, vol. xii., 137.

‡ *Revue Universelle des Mines*, vol. ix., No. 2.

§ *Annales Agronomiques*, vol. ix., No. 7, p. 326 *et seq.*

platinum is then precipated, and there remains in solution chloride of zinc and chloride of sodium. The volume is now made up to 100 c.c. with distilled water. The chlorides in one half of the filtered liquid are then precipitated by the silver solution. Suppose it takes 40 c.c.; multiplying this number by 4 we have 160 c.c., which represents 20 c.c. of the solution of platinum.

Weigh out exactly 0·5 grm. of a chemically pure salt of potassium, nitrate or sulphate; dissolve this salt in a flask of 100 c.c. capacity, in a few c.c. of distilled water, add a little nitric acid, and then precipitate the potassium with 20 c.c. of the platinum solution; make the volume up to 100 c.c. with alcohol of 95 per cent, filter 50 c.c., reduce at a boiling temperature with a little powdered zinc, make up to 100 c.c. The titration by the silver salt obtained with the 50 c.c. of the filtered liquid (or 12 c.c. multiplied by 4 equals 48), subtracted from the original silver titration 160, will represent the chlorine precipitated in the state of chloroplatinate of potassium by 0·5 of a grm. of the nitrate or sulphate of sodium; or 160 minus 48 equals 112 c.c., representing 0·5 of a grm. of nitrate of potassium, or 0·232 of oxide of potassium. For the estimation of any potash salts whatever, proceed exactly in the way which has just been indicated, taking 10 c.c. of the solution of 0·5 grm. of the sample in 100 c.c. The estimation of the chlorides pre-existing in the sample is to be made with the same silver solution (which must be titrated for this purpose), and the number of c.c. found for the half-grm. is to be subtracted from the titre of the silver salt found after reduction by zinc.

Example.—Given 27 c.c. found after reduction by zinc, and 8 c.c. found in the half-grm. of the potash salt, then we will have $27 \times 4 = 108$, $108 - 8 = 100$, and—

$$\frac{100 \times 0{\cdot}232}{112} = 0{\cdot}2076 \text{ for } 0{\cdot}5 \text{ grm.},$$

or 41·52 per cent. of potassium oxide.

Dr. Wiley has had the above method carefully tried by Mr. A. E. Knorr, who finds that the difficulty of determining the end-reaction makes the estimation of the chlorine very uncertain. He is now engaged in some modifications of the process, by means of which he hopes to reach a satisfactory degree of accuracy. The process, if it can be made reliable, is very quick and easy of application.

The Committee believe they have collected in the foregoing notices all the chief processes of determining potash that have any novelty or promise of success. In addition they give some of the results obtained by the application of these principles and variations of them to the analyses of commercial fertilisers.

Dr. C. A. Crampton made at the request of Dr. H. W. Wiley a series of determinations of potash in a commercial fertiliser by the following methods:—

(1) Two grms. were taken, transferred to a filter, and washed with successive portions of cold water of about 2 to 3 c.c. each until the filtrate measured 100 c.c. The entire filtrate was then treated with an excess of barium hydrate in solution, and allowed to stand on the water-bath for some time. A few drops of ammonium hydrate were then added, and a slight excess of a saturated solution of ammonium carbonate. After standing on the water-bath for some time, the mixture was filtered, the precipitate thoroughly washed with hot water, and after the addition of hydrochloric acid filtrate was evaporated to dryness and ignited at a low red-heat. The residue was treated with hydrochloric acid and water, filtered, the filtrate evaporated to dryness, and this operation was repeated until the residue showed little or no blackening on ignition. The residue was then dissolved in a small quantity of water, platinic chloride added in excess, evaporated nearly to dryness, treated with 80 per cent alcohol, filtered on a Gooch crucible, the precipitate washed with alcohol, dried for two hours at 100°, and weighed. A mean of thirty determinations by the above method gave 2·19 per cent of potash (K_2O).

(2) This method was exactly like the preceding, except that hot water was used for washing the samples instead of cold. A mean of fourteen estimations gave 2·91 per cent of potash (K_2O.)

It is therefore evident that cold water is as effective as hot in extracting the potash from the samples by the above methods.

(3) The samples of fertilisers were first ignited to low redness. After the organic matter was thus destroyed the subsequent treatment was the same as above.

Seven determinations were made, the mean of which showed 2·55 per cent of K_2O. This indicates that a portion of the potash was volatilised by ignition. It should be remembered, however, that the ignition was effected over an open flame and not in a muffle.

Two determinations made of the same sample of fertiliser as that used in the above experiments gave 3·07 per cent and 3·00 per cent K_2O respectively.

Mr. W. P. Wheeler made six determinations with the same sample, first igniting in a muffle just to incipient redness, and, after moistening with HCl, proceeding as by the Washington method.

Results.

	Per cent of K_2O.
No. 1	3·06
No. 2	3·04
No. 3	3·05
No. 4	3·02
No. 5	3·02
No. 6	3·01
Mean	3·03

These results show that no potash was lost by the previous ignition, and the Committee is of the opinion that previous ignition at a low temperature in a muffle can be practised without the use of sulphuric acid and with great benefit to the subsequent manipulation.

The object of the comparative trial was to determine the magnitude of the error arising from adding the ammonium carbonate to precipitate excess of barium, and separating the combined precipitate by a single filtration.

It appears from the above that the error amounts to 0·1 per cent. Perhaps by a very careful addition of the barium hydrate, so as to have only the slightest excess for commercial purposes, one filtration might be avoided.

(To be continued.)

PROCEEDINGS OF SOCIETIES.

CHEMICAL SOCIETY.

Annual General Meeting, March 30th, 1886.

Dr. Hugo Müller, F.R.S., President, in the Chair.

The President delivered an Address, of which the following is an abstract:—

The number of Fellows of the Society is now 1459, 31 of these being honorary foreign members. 111 new Fellows have been elected since the last Anniversary Meeting; 8 Fellows have withdrawn, 19 have been removed on account of arrears, and 16 have died, viz., one honorary foreign member, Prof. Hermann von Fehling, and Frederick Allen, Prof. Andrews, F.R.S., E. O. Brown, G. W. H. Clements, Frederick Field, F.R.S., James Higgin, Rev. S. Morris, James Parette, Thomas Spencer, Dr. E. G. Schweitzer, Surgeon-Major Sheppard, Henry Shepheard, Alfred Tribe, Dr. John Smith, W. S. Ward, and Walter Weldon, F.R.S.

104 papers have been communicated to the Society during the year: this is not only a great advance upon the previous year, when the number was 67, but is the

largest number hitherto attained with the one exception of 1880-81, when the number read was 113. The last number of *Transactions* is consequently one-third larger than that of the previous year. The President is inclined to think that this increased activity is due in no inconsiderable degree to the fact that the various new laboratories which have been established in the country during the last few years are now gradually entering upon their full duties; and he is of opinion that we may look forward with confidence to a continuous and steadily increasing development in the pursuance of scientific chemical work in this country.

New bookcases have been filled up at the Society's expense during the year, and thus considerable additional space has been secured for the library.

The subject catalogue of the library has just been issued to Fellows. The Council are greatly indebted to Prof. McLeod, F.R.S., and to Mr. Warington for the assistance they have rendered in preparing this catalogue, as well as to the Librarian, Dr. Thorne.

After dwelling on the recent incorporation of the Institute of Chsmistry by Royal Charter, the PRESIDENT expressed his gratification at being able to testify to the manifest progress in the activity of the Society and to the otherwise prosperous condition of its affairs. In conclusion he proceeded to discuss briefly the conditions which affect the cultivation of scientific chemistry in this country.

It was then moved by Dr. GLADSTONE, and seconded by Prof. THORPE, that the thanks of the meeting be given to the President for his Address, and that he be requested to allow it to be printed. Referring to the publication of the catalogue, Dr. Gladstone said that in looking through it he felt that it not only gave information as to what was, but also what was not, in the library, and it might well serve to lead many of us to make suggestions and to help to fill up gaps from our own shelves. The resolution was unanimously accepted, and was acknowledged by the PRESIDENT.

The Treasurer, Dr. RUSSELL, then read his Report, giving an explanation of the balance sheet. He said that the funds of the Society were in a satisfactory state, the income for the year having been £3743 and the expenditure £3108, leaving a balance in hand of £635, a sum that would make it possible to fund the life compositions received during the year.

Mr. CARTEIGHE moved that the thanks of the Society be tendered to the Treasurer for his services during the past year; this was seconded by Mr. FRISWELL.

Mr. CROOKES proposed a vote of thanks to the Auditors, which was seconded by Prof. CLOWES. Mr. MAKINS replied.

A vote of thanks to the Officers and Council having been proposed by Mr. H. B. DIXON, seconded by Mr. PICKERING, and acknowledged by Dr. ARMSTRONG,—

Mr. HOWARD moved that the thanks of the meeting be given to the Editor, Sub-Editor, Abstractors, and Librarian for their important services to the Society during the year; this was seconded by Mr. J. A. R. NEWLANDS. Mr. GROVES and Dr. THORNE replied.

Prof. Humpidge and Dr. Teed were appointed Scrutineers, and a ballot having been taken the Officers and Council for the ensuing year were elected (see *ante*, p. 166).

Thursday, April 1st, 1886.

Dr. HUGO MÜLLER, F.R.S., President, in the Chair.

Certificates were read for the first time in favour of Messrs. Holland Crompton, 15, Belgrave Road, St. John's Wood, N.W.; George William Saul Hudson, Church Street, Settle, Yorkshire; A. Wentworth Jones, Godington Rectory, near Bichester; William Henry Pendlebury, B.A., Christ Church, Oxford.

The following papers were read:—

35. "*The Determination of Boiling-Points*," By Prof. RAMSAY and SYDNEY YOUNG, D.Sc.

Prof. Ramsay called attention to the device employed by Dr. Young and himself in determining boiling-points (*Phil. Trans.*, 1884, p. 471), which consists in encasing the thermometer bulb in cotton-wool or asbestos; in distilling a pure liquid, the temperature remains constant throughout, owing to the presence of a film of liquid on the thermometer bulb.

DISCUSSION.

Prof. RAMSAY, in reply to a question by Dr. JAPP, said that he was of opinion that in distilling mixed liquids the liquid of higher boiling-point very rapidly expels that of lower boiling-point from the wool, and that hence the proper temperature is indicated almost immediately.

36. "*The Vapour-pressures of Bromine and Iodine, and Iodine Monochloride.*" By Prof. RAMSAY and SYDNEY YOUNG, D.Sc.

After calling attention to the extremely discrepant statements as to the melting- and boiling-points of bromine and iodine, the authors describe their own observations.

Bromine.—The statements of various authors and books vary enormously, the melting-point of bromine being given as $-7{\cdot}3°$ by Regnault and as $-25°$ by Liebig, its boiling-point being stated as 58° by Andrews and 63° by Pierre—these being extreme values.

Two samples of bromine were examined by the authors after being submitted to purification. The melting-point directly observed was between $-7{\cdot}0$ and $-7{\cdot}45$, and from their results generally they infer that it is very near to $-7{\cdot}05°$: the boiling-point of the first sample was 57·65° at 749·8 m.m. pressure, that of the second was 58·85° at 755·8 m.m., but they incline to think that the latter contained some impurity,—perhaps a brominated carbon compound, and give as the corrected number 58°.

Iodine.—The melting-point of iodine was observed to be between 113·8° and 114·1, and they regard 114·15° as the true number; the boiling-point under 760 m.m. pressure was found to be 184·61°.

It was found impossible to obtain useful numbers for iodine monochloride, on account of its instability.

DISCUSSION.

The PRESIDENT remarked that the great discrepancies between many of the earlier determinations of the physical constants of bromine were probably due to the presence of bromine carbon compounds.

Mr. GROVES said that the boiling-point given by Mr. Bolas and himself (59·6°) was determined by using about 2 lbs. of very carefully purified bromine, which certainly contained very little, if any, carbon tetrabromide.

37. "*The Use of the Electric Light to Influence Chemical Change.* By HENRY E. ARMSTRONG.

It is well known that many chemical changes take place under the influence of light which do not occur under otherwise identical conditions in its absence. Schramm's recent experiments have proved that light has a most remarkable effect in influencing the direction of change in cases in which action takes place very readily both in presence and absence of light: thus whereas when chlorine acts on toluene in the dark, chlorotoluenes are formed, in sunlight benzyl chloride is produced; ethylbenzene is excessively sensitive, bromethylbenzene, instead of ethylbromobenzene, being obtained by the action of bromine even in diffused light, and if the treatment be continued in sunlight the dibromide. $C_6H_5{\cdot}CBr_2{\cdot}CH_3$, is produced, whereas cinnamene bromide,—

$$C_6H_5{\cdot}CHBr{\cdot}CH_2Br,$$

is formed if bromine be allowed to act on heated bromethylbenzene; in sunlight, pseudocumene is at once converted into the monobromide, $C_6H_3Me_2{\cdot}CH_2Br$, and more slowly into the dibromide, $C_6H_3Me(CH_2Br)_2$,

whereas mono-, di-, and tri-bromopseudocumene are formed in absence of light. Dr. Armstrong finds that, as was to be expected, the light of the electric arc may be substituted for sunlight. The influence of light may therefore be readily exhibited as a lecture experiment, as the product of the action of bromine in darkness on pseudocumene after removal of hydrogen bromide has no action on an alcoholic solution of silver nitrate, whereas the product obtained under the influence of light at once reacts with such a silver solution. It is merely necessary to drop the bromine into the hydrocarbon in a flask directly exposed to the rays from the arc. Owing to the uncertainty of sunshine, the complex arrangements which are necessary if it is to be used for any lengthened period, and the variation in its intensity, it is conceivable that the use of a powerful electric arc may be of considerable advantage in experiments on the influence of light in promoting or controlling chemical change, and even in some manufacturing operations.

38. "*Some Sulphur Compounds of Barium.*" By V. H. Veley, M.A.

It is shown by the results both of synthetical and analytical experiments that the monohydrate of barium hydroxide is converted into barium monosulphide in accordance with the equation—

$$Ba(OH)_2,H_2O + H_2S = BaS + 3H_2O;$$

known weights of the hydroxide were taken, and a certain weight of the sulphide and of water obtained.

By the action of hydrogen sulphide on an aqueous solution of barium hydroxide, a solution of barium hydrosulphide is formed, from which crystals of the composition $Ba(SH)_2,4H_2O$ separate out; this substance is far more stable than the corresponding calcium compound. The evolution of hydrogen sulphide is concomitant with that of water; when all the latter has been given off the retention of hydrogen sulphide by the anhydrous substance is most marked: only at a red-heat is all the hydrogen sulphide given off and the conversion of the hydrosulphide into the sulphide complete.

A warm saturated solution of barium hydrosulphide dissolves sulphur to give a red liquid, from which crystals of barium tetrasulphide, $BaS_4{\cdot}2H_2O$, separate.

Barium hydroxyhydrosulphide absorbs carbon disulphide, with formation of an unstable barium thiocarbonate.

Discussion.

Prof. Ramsay said that Mr. Veley's account reminded him that years ago, on dissolving sulphur in a solution of barium hydroxide, after crystallising out the thiosulphate, he obtained crystals like those described by Mr. Veley, but of the formula BaS_7.

Mr. Veley, in reply to Dr. Messel, said that he had examined the product made on a large scale by roasting barium sulphate with coal, &c., and had found the crystals to consist of barium hydroxyhydrosulphide with a slight excess of SH_2.

Dr. Teed added that he had always found barium and sulphur present in these crystals in the ratio Ba : S.

39. "*Parabenzylphenol and its Derivatives and a New Benzylphenol.*" By Prof. E. H. Rennie, M.A., D.Sc.

Dinitroparabenzylphenol has been further examined (comp. *Trans.*, 1882, xxxiii., 220); if gently warmed with concentrated nitric acid, it is converted into the trinitro-derivative, but on boiling it with the slightly diluted acid the smell of benzaldehyde is noticed and it is converted into trinitrophenol.

The oily residue left after purification of parabenzylphenol yields a sulphonic acid isomeric with that from parabenzylphenol; its potassic salt crystallises with $2\frac{1}{2}OH_2$. This salt is converted into a nitrosulphonate by nitric acid, and into a bromosulphonate by bromine; the nitrosulphonate is converted by nitric acid into an isomer of dinitroparabenzylphenol, and into a bromonitrobenzylphenol by bromine.

Discussion.

Dr. Armstrong said that the formation of trinitrophenol from dinitrobenzylphenol was analogous to that of dinitrobromophenol from bromonitrobenzylphenol; it was noteworthy that Prof. Rennie had described this latter reaction in 1882, although Widmann in his recent paper (*Ber.*, 1886, 278) speaks of the displacement of an alkyl radicle by NO_2—in the conversion of cumenylacrylic into paranitrocinnamic acid—as altogether without precedent. Prof. Rennie and he, in a communication to the Society in March, 1883, had shown that the supposed trinitrothymol was in reality trinitrometacresol; the formation of this latter body from dinitrothymol was a reaction precisely similar to that described by Widmann.

40. "*Amidodiphenylsulphonic Acid and Azo-dyes from Diphenyl.*" By Thomas Carnelley, D.Sc., and James Schleselman.

p-*Amido-diphenylsulphonic Acid*, $C_{12}H_8(NH_2){\cdot}SO_3H$.—Only one acid of this composition appears to be obtained by the action of strong sulphuric acid on *p*-amido-diphenyl (m. p. 49°) at a temperature of 130°. It is practically insoluble in cold, and but very slightly soluble even in boiling water. The *sodium salt*—

$$C_{12}H_8(NH_2){\cdot}SO_3Na + 2H_2O,$$

and the *barium salt*, $[C_{12}H_8(NH_2){\cdot}SO_3]_2Ba + 4H_2O$, are described.

The following azo-compounds prepared from the acid are described:—

Sodium phenol-p-*diazodiphenylsulphonate*—

$$HO{\cdot}C_6H_4{\cdot}N_2{\cdot}C_{12}H_8{\cdot}SO_3Na.$$

This dyes wool and silk a beautiful yellow.

Sod. resorcinol-p-*diazodiphenylsulphonate*—

$$(HO)_2{\cdot}C_6H_3{\cdot}N_2{\cdot}C_{12}H_8{\cdot}SO_3Na.$$

This dyes silk, wool, and raw jute a beautiful orange.

Sod. quinol-p-*diazodiphenylsulphonate*—

$$(HO)_2{\cdot}C_6H_3{\cdot}N_2{\cdot}C_{12}H_8{\cdot}SO_3Na.$$

This dyes silk and raw jute a very pretty golden amber.

Sod. α-naphthol-p-*diazodiphenylsulphonate*—

$$HO{\cdot}C_{10}H_6{\cdot}N_2{\cdot}C_{12}H_8{\cdot}SO_3Na.$$

This dyes silk, wool, and raw jute a deep reddish brown.

Sod. β-naphthol-p-*diazodiphenylsulphonate*—

$$HO{\cdot}C_{10}H_6{\cdot}N_2{\cdot}C_{12}H_8{\cdot}SO_3Na.$$

This dyes silk, wool, and raw jute a brilliant red.

Discussion.

Professor Meldola remarked that a number of dyes were now prepared from benzidin (diamidodiphenyl), which were of considerable technical importance: Congo-red was one of the most valuable.

PHYSICAL SOCIETY.

March 27th, 1886.

Prof. W. G. Adams, Vice-President, in the Chair.

Mr. A. R. Wright was elected a Member of the Society.

The Chairman read a letter from Dr. Alder Wright, Secretary to the "Tribe Fund" Committee, in which reference was made to the scientific work of the late Mr. Alfred Tribe, and an appeal made for funds to aid in the maintenance and education of his family, which, owing to his early death, have been left in straitened circumstances.

The following communications were read:—

"*On an Arc Lamp convenient for Use with the Duboscq Lantern.*" By Prof. S. P. Thompson.

The old Duboscq lamp, though working well with a series of Grove's cells, is very unsuitable for use with currents from dynamos. Prof. Thompson has employed as a substitute in the Duboscq lantern a lamp commonly known as the "Belfast Arc Lamp." The result is all that can be desired as regards steadiness and regularity

The focussing, that is the adjustment of the arc so that it shall remain unchanged in position, is effected by a wheel below the lantern, which is moved by hand.

"*On a Modified Maxwell's Galvanometer.*" By Prof. S. P. Thompson.

The galvanometer consists of a light frame of copper upon which is a coil of wire. This is suspended between the poles of a horse-shoe magnet, and a piece of soft iron is placed within the coil, but free from it, which concentrates the magnetic force between the poles. The coil is suspended by two silver wires, by which it is in connection with two binding screws on the base of the instrument. This galvanometer is extremely simple in adjustment, and very dead beat; it has also the advantage of being affected to an inappreciable extent by neighbouring magnets and currents, with a current in its own coils; when no current is in it, it is of course quite unaffected. The reading is effected by the ordinary lamp, mirror, and scale arrangement.

"*On the Expansion of Mercury between* 0° *and* −39° C.' By Profs. W. E. Ayrton and John Perry.

On November 14th, 1885, Mr. G. M. Whipple gave the Society the results of the examination of thermometers down to the melting-point of mercury. There was, however, no evidence as to whether the contraction of the mercury continued uniform, as the thermometers were only compared with mercurial ones. The authors have therefore examined this point, and have made a series of comparisons of a mercurial thermometer, lent them by Mr. Whipple, with a constant-volume air thermometer, both immersed in a bath of frozen mercury, which was allowed to gradually become warm. The result obtained was that no certain deviation from a linear law could be detected in the expansion of mercury when temperature was measured by the increase of pressure required to keep a volume of air constant. Hence temperatures down to −39° C. may be correctly measured by a mercury thermometer the stem of which is graduated for equal volumes.

"*On the Expansion produced by Amalgamation.*" By Profs. W. E. Ayrton and John Perry.

It has been accidentally observed by the authors that the amalgamation of brass is accompanied by great expansive force. If the edge of a straight thick brass bar be amalgamated, it will be found that in a short time the bar is curved, the amalgamated edge being always convex, and the opposite concave. The authors imagine that a similar action may be the primary cause of the phenomena pesented by the Japanese "magic mirrors." Japanese mirrors are made of bronze, and have a pattern cast upon the back, and although to the eye no trace of it can be discovered upon the polished reflecting surface, yet, when light is reflected by certain of these mirrors on to a screen, the pattern is distinctly visible in the luminous patch formed. In a paper before the Royal Society they have shown that this is due to the polished side opposite the thinner parts of the coating being more convex than the others,—a conclusion verified by the fact that the pattern is reversed when formed by a convergent beam of light. Such a condition of things would evidently result from a uniform expansive stress taking place over the reflecting surface, the thinner—and consequently the weaker—parts becoming more convex or less concave than the others. The authors have hitherto attributed this inequality of curvature to a mechanical distortion to which the mirrors are intentionally submitted during manufacture, to produce the general convexity of the polished surface; but they now think it possible that the use of a mercury amalgam in the process of polishing may have an effect in the production of this inequality of curvature.

Action of Bromine and Water upon Levulose.—M. Honig.—The principal product is trioxybutyric acid. The production of formic and oxalic acids in appreciable quantities has not been observed.—*Ber. d. Deut. Chem. Gesell.*

CORRESPONDENCE.

THE SPECTRA OF ERBIA.

To the Editor of the Chemical News.

Sir,—Under the above title Dr. Humpidge informs us (Chemical News, vol. liii., p. 154) that he has observed the spectra of erbium and didymium in solid compounds containing these substances, when illuminated by ordinary daylight, the spectra being identical with the absorption spectra of the compounds in solution. He makes this statement in consequence of, and with reference to, the observation of Mr. Crookes that erbia, when illuminated with sunlight or electric light, gives a spectrum with dark bands.

In the *Journal of the Chemical Society* for 1882 (vol. xli., p. 210) occurs the following sentence referring to the mineral rhabdophane:—"When engaged in examining various specimens of British blendes, for the information of M. Lecoq de Boisbaudran in his search for sources of the metal gallium, Mr. Lettsom recognised the bands of didymium by examining with a pocket spectroscope the light reflected from the substance. The characteristic spectrum is easily seen when any didymium compound is so examined, even if the mineral be of a yellow or dark brown colour."

It must be nearly ten years since my friend Mr. W. G. Lettsom first showed me this new use of the pocket spectroscope. In the manuscript of the paper from which the above quotation is made I stated that the nature of this mineral was discovered by a novel use of the spectroscope: the remarks forwarded to me from the Publication Committee by the Editor of the Journal were in effect that this method of examination was not novel, though it might not have been published. As Mr. Crookes remarks in his paper, the only notice with reference to this property of erbia which he had met with was a passing remark of Prof. Clève's, that "the light reflected by dry erbia shows absorption bands."

Whether Prof. Clève or Mr. Lettsom first discovered this property in the rare earths, certainly it appears that Mr. Lettsom first obtained important results by an extensive application of it.—I am, &c.,

W. N. Hartley.

CHEMICAL NOTICES FROM FOREIGN SOURCES.

Note.—All degrees of temperature are Centigrade unless otherwise expressed.

Comptes Rendus Hebdomadaires des Séances, de l' Académie des Sciences. Vol. cii., No. 12, March 22, 1886.

Instrument for Reproducing at will an Invariable Quantity of Electricity.—Marcel Deprez.—The instrument is a voltameter hermetically sealed and thus rendered independent of barometric, hygrometric, &c., fluctuations. The water decomposed by the current during each operation can be reconstituted afterwards by passing a spark between two wires sealed in the upper part of the tube.

An Absolute Spherical Electrometer.—M. Lippmann.—This apparatus consists of two concentric spheres of copper; that in the interior being formed of two movable hemispheres.

Calorimetric Study of the Metals at High Temperatures.—M. Pionchon.—The author gives his results in the form of a table.

Effluviography, or obtaining Images by the Effluve.—D. Tommasi.—The author submits the first results of

his researches on the means of obtaining, by the sole action of the electric effluve or obscure discharge effects such as are realised by the use of light in photography. The following arrangement has been provisionally used to photograph objects without the concourse of light, or, speaking more correctly, to *effluviograph* them. Two metallic brushes arranged parallel to each other are connected each to a pole of the Holtz machine. A gelatino-bromide plate of the same height is placed perpendicularly to the brushes, so that the plane of the sensitive surface contains the edges of these brushes or is very near to them in both directions. The current being established an exposure of some minutes is sufficient. This operation must of course be effected in absolute darkness. It only remains to develop and fix the impression obtained in the ordinary manner. This experiment tends to prove that the effluve produces the same effects as the ultra-violet rays. Consequently there must exist a connection between the two extreme parts of the spectrum, constituted by what the author calls provisionally electrical rays.

Separation and Determination of Copper, Cadmium, Zinc, Nickel and Cobalt, Manganese, and Iron.—Ad. Carnot.—This paper will be inserted in full.

Elements of Milk-Sugar in Plants.—A Müntz.—The author's results are that the gums and mucilages of plants, pectic bodies, &c., contain among the products of their fission galactose identical with that obtained from sugar of milk. These substances exist in vegetable food in such quantity that they can furnish the galactose which enters into the constitution of the milk-sugar secreted by the mammary glands of female herbivora.

Chlorophyll and the Reduction of Carbonic Acid by Plants.—C. Timeriazeff.—On treating an alcoholic solution of chlorophyll with nascent hydrogen (produced by means of zinc and acetic acid) we obtain a reduction product of a straw-colour if the solution is dilute, but if it is concentrated of a reddish brown by daylight, and of a fine ruby-red by lamplight. This substance has a well-defined spectrum characterised especially by the absence of that band I in the red which has hitherto been considered as the most stable peculiarity of all the derivatives of chlorophyll. The second peculiarity of this spectrum is a broad band occupying the place of the band II., and of the two intervals comprised between I. and II. and between II. and III. But the essential property of this substance is that of becoming rapidly oxidised in the air, and at the same time turning green, that is regenerating chlorophyll. It is evidently a body analogous to that which must exist in plants, since etiolated plants become green only by becoming oxidised at the expense of the oxygen of the air. The author gives this substance the provisional name of protochlorophylline, or, more briefly, protophylline.

On Certain Xylenic Derivatives.—A. Colson and H. Gautier.—The authors describe in this memoir the products of a more advanced chloridisation, and a method by which they have converted some of the chlorides into corresponding oxides.

On a Synthesis of Ammonium Cyanide by the Effluve.—A. Figuier.—A mixture of 1 vol. of formene and 2 vols of nitrogen was submitted to the action of the effluve. The formation of ammonium cyanide was quite distinct.

Oxidation of the Fatty Acids.—H. Carette.—In the oxidation of the fatty acids there is produced an acid of the formula $C_{10}H_8O_8$, identical with normal propylene-dicarbonic acid.

Biedermann's Central Blatt fur Agrikultur Chemie.
Vol. xiv., Part 11.

Examination of some kinds of Pumpkins.—Dr. R. Ullbricht.

Digestibility of Clover-Hay, Malt-Sprouts, and Cotton-Seed Meal.—H. P. Armsby.—From the *Amer. Journ. of Science.*

The Quantity of Volatile Acids Excreted by Ruminants.—H. Wilsing.—The total quantity thus eliminated in twenty-four hours is on the average 4 grms., equally distributed between the urine and the dung.

Investigation on Scorched Hay.—E. Mach and K. Portele.—The authors show the great loss of nutritive value which hay undergoes when it is heated to the verge of ignition.

Protective Inoculation against Rabies.—M. Pasteur.—An abstract of a communication made to the Academy of Sciences on October 26th, 1885.

On the Chemical Action of Light.—A. Vogel.—The author shows that cinchona-trees, growing in hot-houses in Europe, develop no quinine in their bark.

The Chemical Composition of the Pollen of the Scotch Fir (*Pinus Sylvestris*).—Dr. A. von Planta.—The pollen of the fir is much poorer in nitrogen, proteine, hypoxanthin, cane-sugar, and colouring matter than that of the hazel. On the other hand, it is richer in non-azotised matters, fatty acids, and starch.

The Occurrence of Choline in Hops.—P. Griess, G. Harrow, V. Griessmayer.—Choline is probably identical with lupuline. Griessmayer is of opinion that the hop contains neither ammonia, trimethylamine, nor choline as such, but merely lecithine. No case is yet known of choline having been obtained from a substance free from lecithine.

Examination of certain Tobacco-Leaves.—Dr. Niederstadt.—These two memoirs require merely to be mentioned.

MEETINGS FOR THE WEEK.

MONDAY, 12th.—Medical, 8.30.
— Society of Arts, 8. (Cantor Lectures). "The Arts of Tapestry-Making and Embroidery," by Alan S. Cole.
TUESDAY, 13th.—Institution of Civil Engineers, 8
— Royal Institution, 3. "The Function of Circulation," by Professor Arthur Gamgee, M.D., F.R.S.
— Royal Medical and Chirurgical, 8.30.
— Photographic, 8.
— Society of Arts, 8. "Progress of the British Possessions in the last Quarter of a Century." by P.L. Simmonds.
WEDNESDAY, 14th.—Society of Arts, 8. "The Treatment of Sewage," by Dr. C. Meymott Tidy.
— Pharmaceutical, 8.
— Microscopical, 8.
THURSDAY, 15th.—Royal, 4.30.
— Royal Society Club, 6.30.
— Royal Institution, 3. "Electro-Chemistry," by Prof. Dewar, F.R.S.
— Chemical, 8. Ballot for the Election of Fellows.
FRIDAY, 16th.—Royal Institution, 5. "Recent Progress in the Coal-Tar Industries," by Sir Henry E. Roscoe, F.R.S.
SATURDAY, 17th.—Royal Institution, 3. "Fuel and Smoke," by Prof. O. Lodge, D.Sc.

LONDON HOSPITAL AND MEDICAL COLLEGE, Mile End, E.—The SUMMER SESSION will commence on Saturday, May 1st. Intending students are advised that under the new regulations of the Royal College of Physicians and the Royal College of Surgeons, it is exceedingly advantageous to enter for the Summer Session. Students now entering are also eligible for the Entrance Scholarships in September.

The Hospital contains nearly 800 beds, and is the largest general hospital in Great Britain.

General fee for lectures and hospital practice, 90 guineas in one sum or 100 guineas in three instalments. The resident and other hospital appointments are free to full students.

Special entries may be made for medical and surgical practice, also for the course of practical surgery.

The London Hospital is now in direct communication by rail and tram with all parts of the Metropolis, and the Metropolitan, Metropolitan District, South Eastern, and East London Railways have stations within a minute's walk of the Hospital and College.

For prospectus and particulars apply to
MUNRO SCOTT, Warden.

THE CHEMICAL NEWS.

THE SOLUBILITY OF SULPHUR IN ALCOHOL.

By ARTHUR G. BLOXAM.

The fact that sulphur crystallises from its solution in hot alcohol in a white prismatic form has not, it appears, been generally noticed in text-books; for Miller's "Inorganic Chemistry" is the only book at my disposal in which I can find it mentioned. This is the more surprising as it has become of considerable importance since the introduction of rubber corks.

I discovered this fact for myself while separating some fat and sulphur with alcohol, being surprised at the deposition of white crystals from the hot solution.

By dissolving sulphur in hot methylated spirit and allowing it to cool slowly in a vessel surrounded by hot water prisms of lengths up to half an inch were obtained; they were brilliantly transparent and so white that they might have been taken for crystals of nitre; but they had become quite opaque and pale yellow in the course of thirty-six hours although kept under the liquid; a low power of the microscope showed very beautifully the change into octahedra.

A more important bearing of the subject is in its relation to the use of rubber corks with alcohol. Mr. G. S. Johnson has called my attention to some crystals which he obtained in extracting a resinous body with alcohol, and which proved to be sulphur derived from the rubber cork connecting his flask and condenser. If a rubber cork be boiled with alcohol for fifteen minutes a good crop of sulphur crystals is obtained on cooling the liquid. It is evident that if alcohol be constantly distilled on to a rubber cork the resulting error will be still greater.

Chemical Laboratory, King's College,
April 7, 1886.

NOTE ON THE VALUATION OF ACETATE OF LIME.

By HARCOURT PHILLIPS.

The two chief processes in use at the present time for the valuation of acetate of lime are known as the "Phosphoric Acid Test," and the "English Commercial Test" or "Sulphate of Soda Test." The former, as is well known, consists in the distillation of the sample with phosphoric acid, and subsequent determination of the acetic acid in the distillate by means of standard caustic soda. In the sodium sulphate process the calcium acetate is converted into sodium acetate by means of sodium sulphate, and this again into sodium carbonate by ignition. The alkali so produced is finally titrated with standard acid, and the amount of acetic acid calculated from the data so obtained. The first of these processes may be made, as I hope presently to show, one of great accuracy. In the second, however, several sources of error are liable to creep in. Inasmuch as the ignition takes place in the presence of sulphates, there is always a danger of these being partially reduced to sulphides by the carbon of the ash, and thus cause an excess of acid to be used over that required by the sodium carbonate. Then, again, unless care be taken to neutralise the free lime which is often present in commercial samples, a result more or less above the truth may be obtained. On the other hand, there is danger of getting a low result through insufficient ignition, and consequent failure to completely convert the sodium acetate into carbonate.

I was lately requested to compare the two processes above mentioned, and in the course of my investigations was led to devise a modification of the "phosphoric acid test" which I think an improvement on the old method, and not liable to the possible errors attending the sodium sulphate process. As the process may prove of some use to chemists engaged in the valuation of acetate of lime, I herewith beg to describe it as conducted in my laboratory:—

One grm. of the sample is placed in a small retort holding about 100 c.c., the arrangement of which will be presently described. Ten c.c. of a 40 per cent solution of phosphoric acid is added, together with as much water as will bring the volume to about 50 c.c. The distillation is then commenced, the flame being so arranged that it may be carried on till not more than 5 c.c., or even less, of fluid remain in the retort. (This may be easily managed, without cracking the retort, by careful manipulation of the flame). At this point the source of heat is removed, and the retort allowed to cool somewhat: 50 c.c. of hot water are then added, and the distillation recommenced and conducted as before. A final distillation with a third 50 c.c. of hot water (making 150 c.c. in all) will be found sufficient to carry over the whole of the acetic acid. The distillate is then titrated with standard soda, using phenolphthaleine as an indicator.

It goes without saying that in making a test of acetate of lime by the distillation process, it is desirable, where economy of time is an object, or where many assays have to be made with the same apparatus, to get the acetic acid

off as quickly as possible. Quick work here means rapid distillation and a minimum of fluid to be distilled. Now rapid distillation with the retort, as usually arranged, is impracticable in the case of acetate of lime, owing to the serious frothing and error occasioned by spirting. The accompanying sketch shows the arrangement I have been in the habit of employing to obviate this difficulty.

The stem of the retort is covered with flannel to prevent loss of heat by radiation, and has the end curved and drawn off so as to pass easily into the condenser. The retort is closed by a caoutchouc stopper carrying a small funnel, the stem of which passes some little way into the retort. When the apparatus is in use the funnel is closed by means of a tapered glass rod, covered with a piece of india-rubber tube. The latter is securely attached to the glass rod by fine wire. This little expedient enables the analyst to replenish the retort with hot water without loss of time. Indeed the whole operation may be completed in from forty to forty-five minutes.

With regard to the strength of acid and alkali used for the titration, the former equalled 0·0079 gramme $Ca''(C_2H_3O_2)_2$ per c.c., and had a corresponding alkali to match it. The end-point was finally settled by means of solutions just half the above strengths, phenolphthaleine being used as an indicator.

The following numbers were obtained by the above

process, when working on carefully prepared, pure, dry sodium acetate. I should mention, however, that sulphuric acid was used to expel the acetic acid, in these experiments, and not phosphoric acid.

Amount of Sodium Acetate taken.	Percentage of Sodium Acetate found.
0·40 grm.	100·12
0·41	99·96
0·32	99·89
0·41	100·14
0·43	99·91
Mean	100·004

The following tests of commercial acetate of lime were all made on the dried and finely-powdered samples, which were kept in closed tubes, and portions removed as required. I attach some importance to the sample being in fine powder, since one containing much tarry matter is liable to enclose particles of acetate which might escape decomposition.

Percentage of Acetate of Lime in Dry Samples.

	By P_2O_5 test.	By Na_2SO_4 test.
No. 1.	65·63	68·43
2.	65·24	66·23
3.	65·37	66 86
4.	65·24	67·80
5.	61·50	66·70
6.	61·28	65·44
7.	62·99	69·38
8.	63·12	66·86

If the foregoing figures teach us anything, they show the necessity there is for a complete revision of the sodium sulphate process for testing acetate of lime. Under some conditions of the ignition the figures come out 2 per cent above those obtained by the distillation method. More frequently, however, the error is greater. Mr. Allen suggests, in the last edition of his admirable "Commercial Analysis," that the ash should, after ignition in a muffle, be moistened with hydrogen peroxide, so as to oxidise the sulphides. This is clearly a step in the right direction, and a closer approximation to the truth should follow its adoption. There is, however, this serious objection to any process involving the decomposition of the acetate by sodium sulphate, namely, that it accounts as acetate of lime some not well-recognised bodies which, like the acetate, give soluble sodium salts when treated with sodium sulphate. It is likely that bodies of the phenol class would act in this way.

If time and opportunity serve, I hope to be able to make some further experiments in this direction.

ON THE

FAILURE OF SULPHATE OF AMMONIA IN MANURING EXPERIMENTS.

By THOMAS BROWN.

WHILST seeking to determine by agricultural experiment the comparative manurial values of sulphate of ammonia and nitrate of soda, I have on several occasions during the past ten years obtained results not only unexpected, but inexplicable. Thus, equal plots have received—(*a*) the same gross weight of, (*b*) the same money values of, and (*c*) equal weights of nitrogen in, sulphate of ammonia and nitrate of soda. The two substances have been used for a variety of crops, sometimes sown as a top-dressing, at others drilled or ploughed into the soil. The resultant benefit to the crop has been most varying and most uncertain; occasionally, to my utter bewilderment, the application of nitrogen in the form of ammonium sulphate has been attended with but a comparative unimportant increase of crop.

In one set of experiments the results obtained from the use of nitrogen, as nitrate, have been far superior, at another equal, in a third inferior, to others obtained where the nitrogen was applied as ammonium sulphate.

I have long sought for the cause or causes of such variations in the results. The only unquestionable facts that presented themselves were—

(*a*.) The experiments demonstrating the inferiority of sulphate of ammonia were made on soils containing over 10 per cent of calcium carbonate.

(*b*.) When the ammoniacal salt has been applied to loams and clays the results were satisfactory.

(*c*.) Unfavourable results have generally followed the sowing of the ammoniacal salt on the surface soil.

(*d*.) Beneficial results have resulted when the salt has been applied to crops that allowed of the salt being buried by the harrow or the plough.

At first I concluded that during the process of nitrification a portion of the nitrogen of the ammoniacal salt was liberated as free nitrogen. That this was not a correct solution appeared when it was observed that on some occasions, on the same class of crop, the results obtained from the application of the ammoniacal salt were superior to those obtained from sodium nitrate. It afterwards suggested itself that a double decomposition might have taken place between the ammonium sulphate and the calcium carbonate in or on the soil to which the former was applied, ammonium carbonate and calcium sulphate being formed.

Several of the unexpected results were obtained from experiments conducted on the farm of Mr. F. I. Cooke, of Flitcham Abbey.

Early this year Mr. Cooke, at my request, kindly sent me 1 cwt. of the surface soil of one of the fields that had been under experiment, in order that at my leisure I might make more careful observations.

This soil I find contains over 17 per cent of calcium carbonate, and over 72 per cent of insoluble silicates: hence it is a light calcareous soil, similar to those occupying a great portion of the surface of West Norfolk. On mixing, in the laboratory, ammonium sulphate with portions of this soil, a strong smell of ammonia was in a short time apparent, becoming in half an hour very powerful. I next added ammonium sulphate in varying amounts to portions of this soil contained in large sized flasks, slightly raking the surface so as to mix the sulphate with the damp soil. In a few minutes ammonia was given off in sufficient abundance to instantly convert reddened litmus-paper deeply blue. This evolution of ammonia continued several days. In one flask the sulphate was covered by about an inch of fresh soil. In this flask no smell of ammonia can be detected, but slightly affected reddened litmus-paper.

I am continuing my observations. I wish to ascertain how much, and in what form, ammonia is liberated, and therefore lost, in definite periods when salts of ammonia are added to this and similar soils. I am also directing attention to the influence of rainfall on the amount evolved. But in the meantime it appears to me so important that this resulting action should be widely and immediately known, that I have determined to hand you these preliminary observations at once. For if ammoniacal salts are used indiscriminately and unwisely, the result will be an unjust condemnation of this valuable source of available nitrogen in agriculture. As an instance of a most unwise use, I would mention applying it as "a top-dressing to wheat crops" on chalk soils.

As I am not aware this action has been before observed by any experimenter, I make you this report in the hope that others may carefully investigate the matter.

Decomposition-Products of Hypophosphoric Acid.—A Joly.—The normal hydrate at the temperature of 70° is split up into metaphosphoric and phosphorous acids.—*Comptes Rendus.*

SUGGESTIONS AS TO THE CAUSE OF THE PERIODIC LAW, AND THE NATURE OF THE CHEMICAL ELEMENTS.*

By THOS. CARNELLEY, D.Sc.,
Professor of Chemistry in University College, Dundee.

(Continued from p. 172.)

As illustrations of this difference between odd and even series we have the following among others; (*a*) It is only the elements printed in thick type (including also the typical elements beginning with Li) which combine with alcohol radicles, those printed in thin type being devoid of that property.† (*b*) Elements printed in thin type are paramagnetic, whilst those in thick type are diamagnetic.‡‡ (*c*) Elements in thick type are generally easily reducible and frequently occur in the free state in nature, or when combined are usually found as sulphides or double sulphides, and only in very few cases as oxides; whereas elements in thin type are only reducible with great difficulty, and (except C, N, and O) *never* occur in the free state in nature, nor (except Mo, Mn, and O) as sulphides, but usually as oxides or double oxides, forming silicates, carbonates, sulphates, &c.§ (*d*) The colour relations,‖ also relations between the melting-points, boiling-points, heats of formation, &c.,¶ only hold good when alternate series are compared.

Now in the case of the hydrocarbon radicles of Table IX. no such difference in the properties of alternate series can be detected, for the members of any one group are all mutually comparable, and are not divisible into two sub-groups as in the case of the elements in Table VIII. (*cf.* however, Baeyer's observation, *vide infra*). Here we have a marked difference, but may it not be due to the series of hydrocarbon radicles in Table IX. being either all odd or all even series, the alternate even or odd series not being represented in the latter table? Such alternate series might be supposed to be generated as follows:—(See next column).

It will be observed that in the above table the system of odd and even series only becomes *complete* at series 10, though it commences *partially* at series 4. Now in the arrangement of the elements in Table VIII. the difference

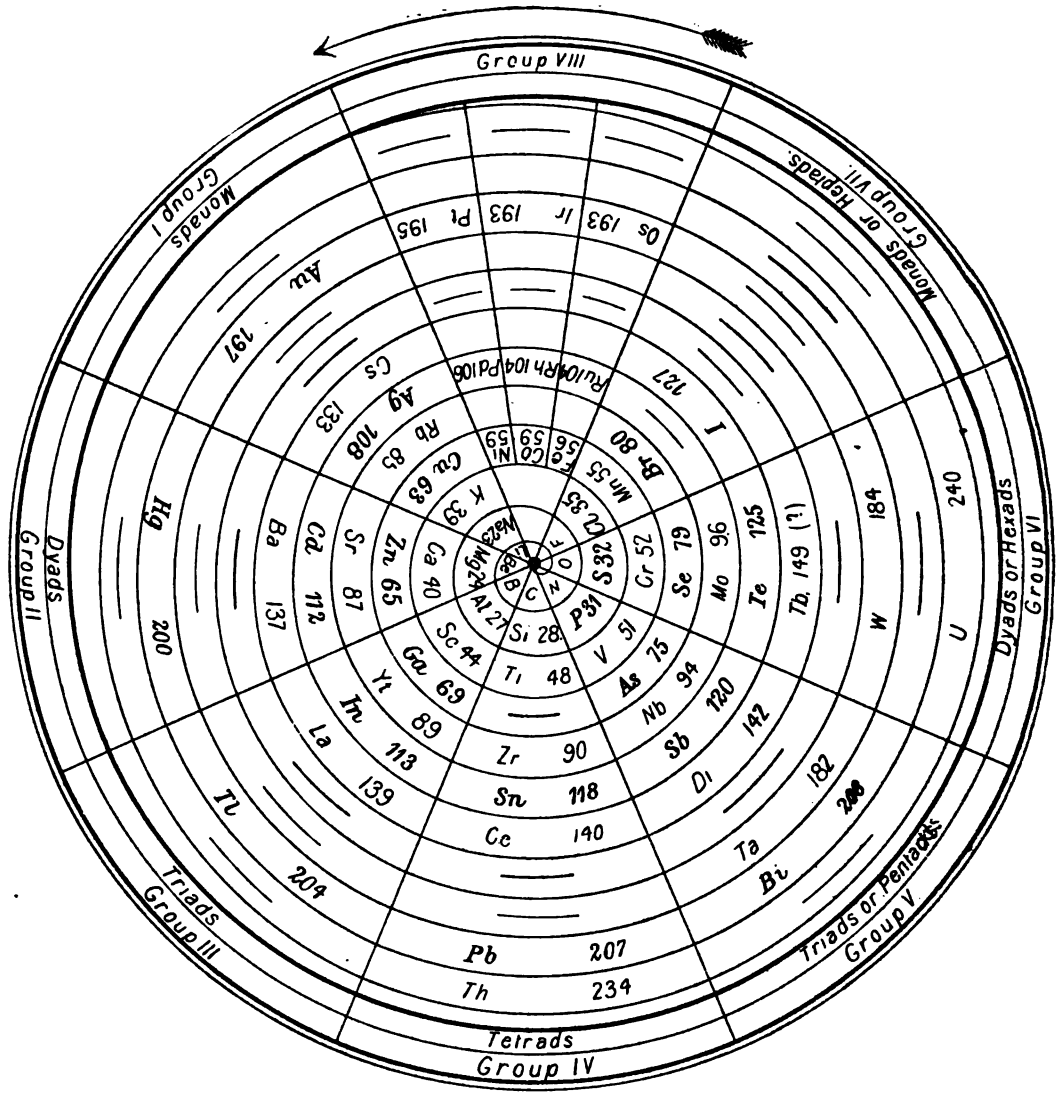
DIAGRAM IV.

ELEMENTS.

(Left handed Spiral)



between odd and even series only becomes evident about the middle of series 3.*

It is also interesting to observe in this connection that Baeyer (*Ber.*, x., 1286) has shown that, if the melting-points of homologous series be compared, this property is materially influenced by *odd and even numbers* in such a way that those compounds containing an *even* number of carbon atoms melt higher than the neighbouring compounds containing an odd number (see Table on preceding page, col. 1).

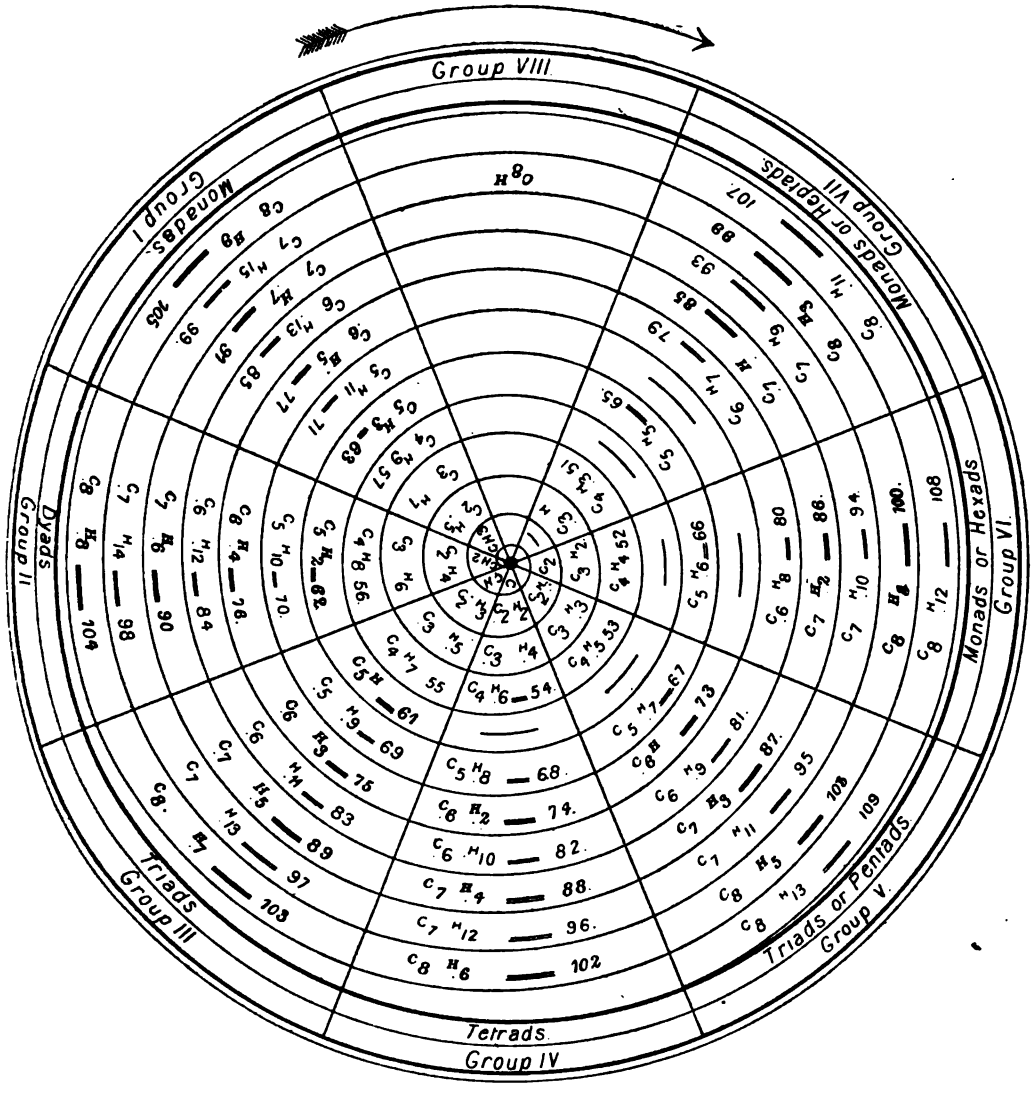
4. The last point of difference in the complete analogy of the elements of Table VIII. to the hydrocarbon radicles of Tables IX. or XI. that it will be necessary to mention is what may be called "inversion of the series." What is meant by this will be better understood from an inspection of Tables VIII. and IX. than from a written explanation. As there arranged the atomic weights of both tables increase across the tables from Group I. to Group VII., indicating thereby that methyl, ethyl, propyl, &c., are analogous to the halogens. And further, Groups I. II. and III. of the elements are represented as usually exhibiting but one atomicity, whilst Groups V., VI., and VII. are represented as triads or pentads, dyads or hexads, monads or heptads, respectively. In the Table of the hydrocarbon radicles, on the other hand, the conditions,

* *Cf.* the examples which have been given above in illustration of the difference between odd and even series of elements.

DIAGRAM V.

HYDROCARBON RADICLES.

(Right handed Spiral)



as regards to the atomicity of the several groups are reversed.

If, however, the hydrocarbon radicles in Table IX. be so arranged that the atomic weight increases across the table from Group VII. to Group I., instead of from Group I. to Group VII., then the condition of things as regards the atomicity of the several groups becomes the same in both tables. Under these circumstances, however, the alkyl radicles, methyl, ethyl, propyl, &c., are represented as analogous to the monad metals of Group I.

On the whole I am inclined to think that the analogy indicated by this latter arrangement is the truer one. It should be stated that whichever arrangement be adopted the relationships between the physical properties of the elements and their compounds and those of the hydrocarbon radicles referred to above in my previous papers, and the conclusions deduced therefrom, hold good in either case.

If the arrangement last proposed be adopted (*i.e.*, the one in which the atomic weights of the hydrocarbon radicles increase across the table from Group VII. to Group I.) then such an arrangement of the hydrocarbon radicles would bear the same relation to that of the elements in Table VIII. which a right-handed spiral bears to a left-handed spiral. Diagrams IV. and V. will make this clear. The spiral arrangement represented in IV. is in principle the same as that first adopted by Baumhauer (1870) and subsequently modified by Huth (1884). The

latter determines the position of the elements in the spiral by measuring off distances on the radii of the spiral proportional to the respective atomic weights.

(To be continued).

REPORT OF COMMITTEE OF THE CHEMICAL SOCIETY OF WASHINGTON, ON THE "METHOD OF STATING RESULTS OF WATER ANALYSES."

The Chemical Society of Washington, at the meeting of November 12th, 1885, appointed a Committee to consider the present state of water analysis, and to present a method of stating analyses adapted for general use, in order that those hereafter published may be readily compared with each other and with future work. This Committee reported February 11th, 1886, and was authorised to prepare an abstract for publication, in order to call the attention of chemists to the subject. The Society earnestly recommends the adoption of the scheme, which is herewith briefly presented. The full text of the Report will be published in the next *Bulletin* of the Society.

Abstract.

Water analyses are usually made to answer one of three questions, viz.,—

1st. Is the water useful medicinally?

2nd. Is it injurious to health? and

3rd. Is it suitable for manufacturing purposes?

Many books relating to water were published during the eighteenth century, but accurate chemical analysis was not attempted until about 1820. As the earlier analyses were isolated, rare, and made for special purposes, the form of the statement was of little importance if it was only intelligible. At the present time, however, water analyses are very numerous. An examination of about a thousand shows some forty-two methods of stating quantitative results, there being sometimes three different ratios in the report of one analysis. Such discrepancies render comparisons difficult and laborious. The various methods of statement may be classified under the following general forms:—

1. Grains per imperial gallon of 10 lbs., or 70,000 grains.

2. Grains per U.S., or wine gallon of 58,372 grains.

3. Decimally, as parts per 100, 1000, 100,000, or 1,000,000.

4. As so many grammes or milligrammes per litre.

The last two would be identical if all waters had the same density, but, as the densities of sea water, mineral waters, &c., are much above that of pure water, it is plain that the third and fourth modes are not comparable.

The Committee therefore unanimously recommends—

1st. That water analyses be uniformly reported according to the decimal system, in parts per million or milligrammes per kilogramme, with the temperature stated, and that Clark's scale of degree of hardness and all other systems be abandoned.

2nd. That all analyses be stated in terms of the radicals found.

3rd. That the constituent radicals be arranged in the order of the usual electro-chemical series, the positive radicals first.

4th. That the combination deemed most probable by the chemist should be stated in symbols as well as by name.

The abandonment of Clark's *scale* has been recommended by Wanklyn and Chapman, and the recommendation made by the Committee does not involve the disuse of his method, but merely the bringing of it into accord with the decimal system,—the changing from grains per gallon to milligrammes per kilogramme.

The last conclusion was deemed desirable from the frequent confusion in the statement of the iron salts and of the carbon oxides.

The Committee is unanimously of the opinion that analyses in the form recommended will prove quite as acceptable to boards of health, and to the public in general, for whom such analyses are often made, as if presented in the mixed and irregular forms commonly adopted.

The Committee also feels sure that people in general are better able to form a definite idea of the character of a water from a report stated in parts per 100, parts per 1,000,000, &c., than from one expressed as grains per gallon, the latter being a ratio wholly unfamiliar to any but those in the medical or pharmaceutical professions.

(Signed) A. C. Peale, M.D.
Wm. H. Seaman, M.D.
Chas. H. White, M.D.

ANALYSES OF COMMERCIAL FERTILISERS.*

(Continued from p. 176.)

Mr. Wheelrr also made some determinations to compare the methods of double and single filtrations, with the following results:—

After weighing the precipitate of K_2PtCl_6 in a Gooch crucible, it was reduced in a low red-heat in a current of hydrogen, the potassium chloride washed out, and the resulting platinum weighed. The first column in the following Table shows the percentage of K_2O calculated from the double chloride, and the second the same from the platinum.

First method.—Addition of barium hydrate in slight excess, filtration, precipitation of excess of barium by ammonium carbonate, determination of potassium in filtrate.

	Per cent of K_2O.	Per cent of K_2O.
No. 1..	12·26	12·30
No. 2..	12·08	12·10
No. 3..	12·22	12·16
Mean.. ..	12·12	12·19

Second method.—Addition of barium hydrate, and then, before filtering, of ammonium carbonate, filtering and proceeding in the usual way.

	Per cent of K_2O.	Per cent of K_2O.
No. 1..	12·06	12·04
No. 2..	12·04	12·02
No. 3..	12·12	12·08
Mean.. ..	12·07	12·05

From the above it is seen that the error arising from a single filtration, as in the previous case, amounts to about 1 per cent. The percentage of potash calculated from the double salt is practically the same as from the platinum. Hence there appears to be no necessity for reducing the platinum in a current of hydrogen and a re-calculation of the results. Dr. Crampton, working by his first and second methods, already described, obtained the following results with the same sample that Mr. Wheeler used in the numbers just given. In the second column will also be found the results calculated from the reduced platinum.

* From the *Proceedings* of the Second Annual Meeting of the Association of Official Agricultural Chemists, at Washington, D.C., September 1, 1885. Edited by Charles W. Dabney, Jun., Ph.D., North Carolina Agricultural Experiment Station, Secretary.

	Per cent of K_2O.	Per cent of K_2O.
No. 1..	10·23	10·17
No. 2..	10·36	10·08
No. 3..	10·14	10·02
Mean.. ..	10·21	10·09

From the same sample Dr. Crampton obtained, using the Washington method, as a mean of four analyses, 10·92 per cent of K_2O.

The above results show that by reduction of the precipitated and hydrogen gas a reliable check on the accuracy of the analyses is obtained. But the numbers secured by reduction agree so closely with those got directly from the double chloride that for commercial purposes the additional work cannot be recommended.

The difference in the results obtained by the two experimenters above shows either the difficulty of getting even samples of the same fertiliser, or that the magnitude of the personal equation is greater in the estimation of potash than it is for most other substances.

There is one precaution that should always be taken in potash determinations, viz., not to have any ammoniacal fumes in the room during the evaporation after the addition of the platinic chloride.

Illustrating the effect produced by this cause, six determinations of potash in a fertiliser in a room free of ammonia, and four others made in a room in which other analysts were working on the estimation of phosphoric acid, are given. The ten determinations were all of the same sample and were made by one person, namely, Mr. G. L. Spencer. The sample was of the same fertiliser as the one used by Messrs. Crampton and Wheeler, as given above.

The per cent of K_2O determined in room free of ammonia is in first column, and from room containing ammonia in second column.

	Per cent.	Per cent.
No. 1..	3·03	3·17
No. 2..	2·91	3·85
No. 3..	2·94	3·65
No. 4..	2·99	3·64
No. 5..	2·93	0·00
No. 6..	3·07	0·00

From a study of the above results it does not appear that any advantage is obtained from the methods employed to shorten the time and diminish the labour of a potash determination.

Six samples of fertilisers containing potash were prepared by the Committee in as uniform a manner as possible, and were sent in sealed packages to the members of the Association.

Following is a description of the samples:—

No. 1. Commercial kainite.
No. 2. Commercial superphosphate.
No. 3. Commercial high-grade phosphate, with nitrate of potash.
No. 4. Tankage and potash.
No. 5. Tobacco-stems and ground bone.
No. 6. Ground bone and nitrate of potash.

Accompanying the samples the following circular letter was sent:—

Washington, D.C., July 2, 1885.

SIR,—In behalf of the Committee on Potash appointed by the Association of Official Agricultural Chemists at the Philadelphia meeting last September, I have sent you by express samples of fertilisers containing potash, numbered 1 to 6 respectively.

Will you determine in them water and potash by the method recommended by the Association, and also by the method usually employed by you, or by any other method you may desire to try? When the work is done please report results to me with detailed accounts of methods employed other than that recommended by the Association. The names of the Analysts are to be received by the Chairman of the Committee in strict confidence, and are not to be made known in connection with their results.

All the results received will, however, be tabulated and reported to each analyst contributing, that he may see how his work compares with that of other chemists. The greatest care has been taken to secure uniformity in the samples sent out. Inasmuch as the Association will meet again in Washington early in September, it is desired that you forward the results of your work as soon as possible.

Respectfully, H. W. WILEY,
Chairman Potash Committee.

Owing to the late date at which the samples were sent out, the Committee has not received as many returns as had been expected.

In all, returns have been received from four laboratories, containing the results of the independent work of eight chemists.

These returns have been collected in two Tables, the first of which gives the results of the analyses by the Philadelphia method, and the second by slight variations therefrom, explained in the subsequent notes.

Analyses of Samples of Commercial Fertilisers by Philadelphia Method.

Mean	12·55	4·03	2·14	2·41	3·39	3·42

Method A.

Ignite sample at low red-heat; exhaust residue with water, acidulated with hydrochloric acid; add barium hydrate; filter; precipitate excess of barium with ammonium carbonate; filter; evaporate; filtrate to dryness; ignite residue at low red-heat; exhaust with water; filter; precipitate with excess of platinic chloride, and proceed in the usual way.

Method B.

Take 2 grms. of sample, digest on steam-bath fifteen or twenty minutes with 25 c.c. of water, transfer to a filter, wash with successive small portions of hot water until filtrate and washings amount to 100 c.c. The filtrate is treated with saturated solution of barium hydrate in slight excess, heated, and filtered. To filtrate is added a little ammonium hydrate, and then ammonium carbonate in slight excess, precipitate filtered off and washed, and the filtrate and washings evaporated to dryness and ignited. The dry residue is treated with a little hot water, filtered, a little hydrochloric acid added, evaporated to a thick syrup, treated with 80 per cent alcohol, allowed to stand twelve hours, filtered through a Gooch crucible, dried at 105° to 110°, and weighed.

Method C.

Two grms. of sample boiled with 100 c.c. water, and washed with 200 c.c. water on a small filter. Precipitate hot with 35 c.c. saturated solution of barium hydrate, and

filter. Add lump of ammonium carbonate to filtrate, and heat until excess of carbonic acid has gone off. Filter off barium carbonate, add about ½ a grm. of oxalic acid, evaporate to dryness in platinum dish, and ignite at a low red-heat to destroy organic matter and nitrates. Filter on a 5-centimetre filter-paper into a 50 c.c. platinum dish, add 2 c.c. dilute hydrochloric acid, then excess of platinic chloride, and proceed according to Crookes's "Select Methods."

Methods F' *and* G'.

These methods were the same as the one adopted in Philadelphia, with the exception that an ordinary filter-paper was used instead of a Gooch crucible for collecting the precipitate.

After a careful consideration of all the results which have come to the notice of your Committee, we do not think that the general principles of estimating potash should be greatly changed from those given in the report at the Philadelphia meeting. We therefore beg to suggest, for the consideration of the convention and for adoption for the forthcoming year, the following—

Method for Estimating Potash.

In case the potash is contained in organic compounds like tobacco-stems, cotton-seed hulls, &c., it is to be saturated with strong sulphuric acid, and ignited in a muffle to destroy organic matter. Pulverise the fertiliser (200 or 300 grms.) in a mortar; take 10 grms., boil for ten minutes with 200 c.c. water, and, after cooling and without filtering, make up to 1000 c.c., and filter through a dry paper. If the sample have 10 to 15 per cent K_2O (kainite), take 25 c.c. of the filtrate; if from 2 to 3 per cent K_2O (ordinary potash fertilisers), take 100 c.c. of the filtrate. In each case make the volume up to 150 c.c., heat to 100°, and add, drop by drop, with constant stirring, slight excess of barium chloride; without filtering, in the same manner add barium hydrate in slight excess. Filter and wash until precipitate is free of chlorides. Add to filtrate 1 c.c. strong ammonium hydrate, and then, drop by drop, a saturated solution of ammonium carbonate until excess of barium is precipitated. Add now in fine powder 0·5 grm. pure oxalic acid, or 0·75 grm. ammonium oxalate. Filter, wash the porcelain dish free of chlorides, evaporate filtrate to dryness in a porcelain dish, and, holding dish with crucible tongs, ignite carefully over the free flame below red-heat until all volatile matter is driven off.

The residue is now digested with hot water, filtered through a 5-centimetre filter, and washed with successive portions of 2 c.c. water until the filtrate amounts to 30 c.c. To this filtrate, after adding 2 drops of strong hydrochloric acid, is added, in a porcelain dish, 10 c.c. of a solution of 10 grms. of platinic chloride in 100 c.c. of water. The mixture is now evaporated on the water-bath to a thick syrup, treated with 85 per cent alcohol, well rubbed with the stirring-rod, washed with 85 per cent alcohol by decantation, collected on a Gooch crucible, washed with 85 per cent alcohol, afterwards with 5 c.c. ether, dried for thirty minutes at 100°, and weighed. It is not necessary to check the results by washing out the precipitate and re-weighing the crucible, or by reducing its weight after washing out the potassium chloride. We recommend the continuance of the use of the factor 30·56 for converting K_2PtCl_6 to KCl, and 19·308 for converting to K_2O. We further recommend that the Committee on Potash which may be appointed for the coming year distribute at an early date samples of fertilisers to members of the Association and others interested, with such recommendations as may seem best suited to secure a thorough trial of this and all new methods which may appear to promise success.

Respectfully submitted. H. W. WILEY, Chairman.
W. J. GASCOYNE.
CLIFFORD RICHARDSON.

(To be continued.)

PROCEEDINGS OF SOCIETIES.

PHYSICAL SOCIETY.

April 10th, 1886.

Prof. BALFOUR STEWART, President, in the Chair.

THE following communications were read:—

"*On the Cause of the Solar-Diurnal Variations of Terrestrial Magnetism.*" By Prof. BALFOUR STEWART, LL.D., F.R.S.

The author commenced by reviewing various theories that have been advanced to account for the solar-diurnal inequalities of terrestrial magnetism. That they can be due to the direct magnetic action of the Sun is highly improbable, since terrestrial analogies would lead us to infer that matter at the temperature of the Sun is quite incapable of possessing magnetic properties, and also from the fact that changes in the range of the daily variation lag behind corresponding solar changes in point of time. The hypothesis of Faraday, that the observed variations are the result of the displacement of the magnetic lines of force due to the varying temperature, and consequently varying magnetic permeability, of the atmospheric oxygen, is disproved by the fact that there is no agreement between the chief magnetic variations and those of the temperature of the great mass of the atmosphere, though it is certain that there must be some effect due to this. The Earth-current hypothesis is quite unable to explain one of the chief characteristics of these variations, that they are half as great again at periods of maximum as at those of minimum sun-spot frequency: Sir George Airy has, moreover, been unable to detect any resemblance in form between the regular diurnal progress of the magnet and that of earth-currents. We seem, therefore, compelled to seek for the cause of the variations in the upper atmospheric regions, and we cannot imagine such a cause to exist in any other form than that of a system of electrical currents. That currents may, and actually do, exist at great heights is shown by the Aurora, which is unquestionably an electric current, and manifests a close connection with the phenomena of terrestrial magnetism. The great increase of magnetic variation at epochs of maximum sun-spot frequency can also be accounted for on this supposition. Prof. Stokes has remarked that an increase in the radiating power of the Sun would probably imply not only an increase in general radiation, but a special and predominant increase in such actinic rays as are probably absorbed in the upper regions of the Earth's atmosphere. These regions will therefore greedily absorb the new rays, their temperature will rise, and, as is known to be the case for gases, the electrical conductivity will be increased. Thus, even if we imagine the general atmospheric current to remain constant, a greater proportion of it would be thrown at such times into those heated portions which had become good conductors, but it is also probable that the current itself would be increased. Assuming the existence of currents at great altitudes, the regularity and general characteristics of the diurnal variations would seem to point to a direct magnetic action of the currents rather than to any general induced change in the magnetic system of the Earth, which, to produce the observed results, would have to be of a very artificial character. The diurnal variation of the declination, attaining a westerly maximum at 2 p.m., north of the Equator, and an easterly maximum at the same time south of it, would suggest the existence of currents flowing northward and southward from the Equator to the Poles, attaining a maximum in each hemisphere about two hours after the Sun had passed the meridian. To supply this flow we should probably have to assume the existence of vertical currents ascending from the equatorial regions of the Earth. At this point Dr. Schuster has endeavoured to apply mathematical analysis to the subject. From the

recorded observations at Greenwich, Lisbon, Hobarton, St. Helena, and the Cape, he has shown that the work done by a magnetic pole describing a closed path in a horizontal plane at those places is equal to the work done upon it, and consequently no part of the ascending current can be enclosed by the path. Hence the potential at those places obeys the law expressed by the equation—

$$\frac{d^2V}{dx^2} + \frac{d^2V}{dy^2} + \frac{d^2V}{dz^2} = o.$$

From this Dr. Schuster has deduced two possible expressions for the potential, one referring to a system of currents above our heads, and the other to one beneath our feet. From the first of these expressions it follows that, for latitudes greater than 45', the maximum of horizontal force should coincide with the minimum of vertical force, and *vice versa*, and this is actually the case at Greenwich; while the opposite should hold if the influencing system were beneath us. For latitudes below 45° the reverse of the above should be the case, and the observations at Bombay, though less decided than those at Greenwich, would seem to point the same way. On the whole, then, it must be said that the results of the first attempt are very encouraging, and point to the supposition that the greater part of the disturbing cause lies outside the Earth's surface.

In a discussion that followed, Mr. Whipple remarked that recent observations in high latitudes seem to show that the Aurora is not always at such a great height as is usually supposed.

Prof. A. W. Rücker cited the well-known case when an observer saw what appeared to be a meteor fall into the Sun, while simultaneously, or nearly so, there was recorded a magnetic disturbance on the Earth, as showing a direct solar action.

Mr. Whipple, however, stated that he had recently examined this point, and believed that the very slight notch in the record, many similar to which have occurred since, was of an accidental nature, and a mere coincidence.

Prof. McLeod suggested that the Earth-current theory might be tested by observations at the bottom of a mine, where, according to the theory, the disturbances should be reversed.

Prof. Adams believed that there was nothing physically impossible in the existence of such currents, as the author imagines.

"*On a Relation between the Critical Temperatures of Bodies, and their Thermal Expansions as Liquids.*" By Prof. A. W. Rücker, F.R.S., and Prof. T. E. Thorpe, Ph.D., F.R.S.

A paper by the authors, bearing the above title, was published in the *Journal of the Chemical Society* for April, 1884. The substance of the paper was as follows:—Prof. Mendelejeff has shown that that the expansion of liquids under constant pressure between 0° C. and their boiling-points may be expressed by means of the very simple formula—

$$V_t = \frac{1}{1 - k\,t},$$

V_t being the volume at t° C. (that at 0° being unity), and k a quantity which differs for different substances, but which may for any one substance be considered invariable between 0° C. and the neighbourhood of the boiling-point. From this law the authors have obtained as a deduction the following expression for the critical temperature (T_c) of any liquid—

$$T_c = \frac{T\,V_t - 273}{a\,(V_t - 1)},$$

where V_t is the volume at t° C., T the absolute temperature, and a a quantity which is very nearly constant for all substances, and which was shown to be very nearly 2.

In a recent paper (*Ann. Chem. Phys.*, March, 1886) MM. A. Bartoli and E. Stracciati have discussed both of these formulæ, and have applied them to cases in a manner never intended by the authors. They have expanded Mendelejeff's formula into the series—

$$V_t = 1 + k\,t + k^2\,t^2 + k^3\,t^3 \ldots .$$

which is a geometrical progression, and they have objected to it that the results of Piure, Kopp, Him, Thorpe, &c., do not give for the coefficients t, t^2, t^3 quantities in geometrical progression. The results of these observers are given in the usual form—

$$V_t = 1 + a\,t + b\,t^2 + c\,t^3, \ldots .$$

but, owing to unavoidable errors of experiment, the constants c d of different observers differ very largely, and Mendelejeff's simple expression gives the results of all qnite as accurately as the facts will allow. MM. Bartoli and Stracciati have then criticised the expression given by the authors, and have applied it to determine the critical temperature of water from its expansion to 200° C., whereas the original expression is only given as applicable as far as the boiling-point. They have further recorded a number of critical temperatures calculated by the formula to tenths of a degree, for which the constant a would require to be known to 0·025 per cent, whereas there is no reason for supposing it known to within 1 per cent or more.

NOTICES OF BOOKS.

A Short Manual of Chemistry. Vol. I. Inorganic Chemistry. By A. Dupré, Ph.D., F.R.S., and H. Wilson Hake, Ph.D., F.C.S. London: C. Griffin and Co.

This manual differs favourably from many of the elementary works on chemistry which have appeared in such alarming numbers. Though designated as "short" on the title-page, it does not carry brevity to such an extent as to render meagreness unavoidable. Again, we do not find the rarer elements ignored, as is too often the case. On the contrary, they are here described quite as fully as is compatible with the extent of our definite knowledge concerning them, and with the compass of the work. Lastly, there is no reference in the Preface to any "Syllabus" or to any contingent examination; nor is there as a tail-piece a list of questions set by any examining body.

In the second paragraph of the Preface we find an attempted explanation of the multiplicity of chemical manuals with which we cannot fully agree:—"We believe that the very multiplicity of text-books already published tends to show a want felt, but not yet satisfied." We can scarcely put so charitable a construction upon the appearance of a majority of the manuals and "manualettes" which it has been our duty to notice. Were their authors striving after some ideal in arrangement and exposition not yet realised, they would not, we think, have been cast so very decidedly in the same mould. This is, however, a very secondary consideration as far as the present work is concerned.

Drs. Dupré and Hake may fairly be congratulated on the eminently lucid character of their exposition of chemical truths. We notice also with pleasure that they do not, like too many authors, allow the student to go away with a belief in the absolute character of certain laws, such as those of Dulong and Petit, Neumann, &c., which after all are mere approximations, trustworthy within certain limits only.

In the chapter on the "Classification of the Elements" due credit is given to Mr. J. A. R. Newlands as the first discoverer of what is now known as the "periodic law."

On the subject of water-supplies the authors take the medical view rather than the purely chemical. Whilst admitting that any substance other than oxygen and hydrogen may be regarded as impurities, and that in con-

sequence all natural waters are more or less impure, they add the important qualification that—"Considered, however, in relation to its use for drinking and other domestic purposes, it is more or less misleading to call every such substance, dissolved or suspended, an impurity, but only such as are distinctly harmful should be regarded as such." Hence they would certainly not include, *e.g.*, the calcium carbonate contained in the Metropolitan water-supply among the "tons of impurities which Londoners contentedly swallow."

We notice that the authors repudiate the term "metalloids" still applied by certain foreign chemists to the non-metals, and they quote the suggestion of Prof. Tilden that this term should better be applied to a number of elements which occupy a somewhat doubtful place between the metals and the non-metals, being referred sometimes to the one and sometimes to the other of these classes.

The work before us may, in fine, be pronounced useful not merely as a text-book for the student, in the narrower sense of the term. Readers who may wish to acquire a general knowledge of chemistry, apart from any special or professional aims, will find this volume well suited to their purpose.

Rudiments of Chemistry. By TEMPLE ORME. London: Swan Sonnenschein, Le Bas, and Lowrey.

THE author of this little book tells us that his "object has been to explain the nature of chemical research and of scientific induction, in so far as that can be done by means of simple experiments and without the use of the Atomic Theory." Mr. Orme tells us further that he has tried his utmost not to introduce anything original into a book intended only for elementary instruction. He adds the remark, however, that in some cases "the teaching is very much at variance with that of popular text-books." One instance of this we notice with reference to the respiration of animals and of plants. After mentioning that carbonic acid is produced by the respiration of animals, he goes on to state that "plants also breathe, but the effect they have on the atmosphere is the exact opposite to that of animals." It is now considered that the true respiration of plants is analogous in its results to that of animals, whilst the process by which they decompose carbonic acid, fixing the carbon and setting free the oxygen, is a process of assimilation or nutrition.

The work contains a number of miscellaneous questions and examples, but there is no reference to preparing for any examination.

Experiments on Ensilage, conducted at Rothamsted, Season 1884-85. By Sir J. B. LAWES, LL.D., F.R.S., and J. H. GILBERT, LL.D., F.R.S.

THE following are the principal results of a prolonged series of experiments carefully performed by the authors. They find that it would require a larger area of land to obtain a given quantity of dry food-substance in crops grown for ensilaging than to obtain the same quantity in roots. The substitution of ensilage-crops for roots on a large scale would necessitate a considerable change in the course of cropping. It would lessen the area under cleaning crops, and consequently lessen the area suitable for growing grain for the market. Where ensilaging is only adopted instead of hay-making, it is improbable that it will be substituted for it entirely, and if only partially the process would only have a comparatively limited application. Or if it be extended to the natural and artificial grasses usually fed on the land, an expensive mode of feeding would be substituted for a natural one.

We may here remark that the inducement to abandon haymaking has become very small since the Gibbs drying machine enables the farmer to obtain excellent hay even in the worst weather.

In ensilage there is some total loss of nitrogenous matter; but there was a much larger amount of it degraded from the albumenoid condition to compounds incapable of forming the nitrogenous substances of animal increase or of milk. The results obtained do not favour the opinion that woody fibre of a given degree of induration is rendered more soluble, and consequently more digestible.

When analysed, the milk of cows fed on mangels invariably showed a higher percentage of both total solid matter and butter-fat than that of silage-fed cows. This fact proves that the diet of cows is not without an appreciable influence upon the composition of the milk. The authors, whilst thus declaring the ensilage milk poorer than that obtained from cows fed on roots, yet state that "quite consistently with the observations of others on the same point, the milk of our silage-fed cows was judged, both by colour and by taste to be richer than that of the mangel-fed cows." Here, therefore, we have evidence of the untrustworthiness of taste and colour as indications of quality.

This report, evidently drawn up with judicial impartiality, and based on careful experiments, will not be welcome to enthusiasts who entertain the wild and unchemical idea that "produce which is itself not good food can be made good food by being ensilaged."

Coca, Cocaine and its Salts: their History, Medical and Economic Uses, and Medicinal Preparations. By W. MARTINDALE, F.C.S. London: H. K. Lewis.

THIS work is in its tendency medical and pharmaceutical rather than chemical. We find no mention of any product found in the coca-leaves other than cocaine, hygrine, ecgonine, coca-tannin, and coca-wax. Cocaine does not appear to produce any well-characterised reactions. No colouration is produced on dissolving cocaine or its hydrochlorate in pure, cold, concentrated sulphuric acid. "Some samples of them" (apparently of the salts of cocaine) give a faint evanescent yellow colour, and others take a magenta tinge, which passes to a brownish yellow and fades away."

The effects of coca upon the human system are very contradictory. Von Tschudi and Pöppig give very doleful accounts of the intemperate use of coca by the inveterate *coqueros*. Weddell, on the contrary, who has more recently travelled in the districts where it is most in use, met with no results at all resembling those described by Pöppig. Even Von Tschudi admits that the moderate use of coca is not merely innoxious, but that it may even be very conducive to health. Its cultivation is even recommended as likely to be remunerative in Jamaica, Ceylon, India. But in consequence of the sensational reports which have been set abroad planters and merchants would very probably have to encounter one of those "Anti"-societies in which England is so fruitful, and which would doubtless by its emissaries denounce them as ministering to "a degrading vice."

The little work before us is printed in blue ink on a pale green paper. It is very probable that this arrangement would prove less fatiguing to the eye than the sharp contrast of black and white which is conventionally adopted.

CHEMICAL NOTICES FROM FOREIGN SOURCES.

NOTE.—All degrees of temperature are Centigrade unless otherwise expressed.

Comptes Rendus Hebdomadaires des Séances, de l' Académie des Sciences. Vol. cii., No. 13, March 29, 1886.

Theory of Dynamo-Electric Machines acting as Recipients.—Giza Szarvadz.

Election of Perpetual Secretary for the Physical Sciences.—M. Vulpian has been elected in place of the late M. Jamin after an obstinate contest.

An Absolute Electrometer with Continuous Indications.—E. Bichat and R. Blondlot.—These two papers require the accompanying diagrams and illustration.

Combinations of Vanadic Acid with the Oxygen-Acids.—A. Ditte.—Vanadic acid forms definite compounds with certain oxygen acids, some of which can be isolated in the free state in the crystalline form, whilst others have as yet only been obtained in the form of salts. The author describes here the former class, the compounds formed with sulphuric, phosphoric, arsenic, iodic, and molybdic acids. The compounds formed with tungstic, silicic, oxalic, and tartaric acids belong to the second class.

Action of Platinum at a Red Heat upon Phosphorous Fluorides.—H. Moissan.—Not merely the phosphorus but also the fluorine appear to be fixed by the platinum. Platinum-sponge which has been thus treated is heavy, in part melted, and if treated with sulphuric acid in a lead vessel covered with a plate of glass hydrofluoric acid is liberated.

Splitting up of Compounds optically inactive by Compensation.—E. Bichat.—The author maintains that the experiments of MM. Scacchi and Wyrouboff (*Comptes Rendus*, Feb. 22) merely prove that the splitting up of sodium-ammonium racemate is possible merely between certain temperatures. He finds that the fission takes place only when the solution is exposed at a sufficiently low temperature to the temperature of atmospheric dust.

A Photo-chemical Reaction of Schützenberger's Oxymetric Action.—Victor Jodin.—In a former communication (*Comptes Rendus*, cii., 264) the author laid before the Academy some older experiments the conclusion from which was that light, outside of physiological conditions, produces in chlorophyll oxidising actions very different from the reducive reaction which characterises the *chlorophyllic act, i.e.*, the decomposition of carbonic anhydride. The recent observations of M. Regnard seem, on the contrary, to show that chlorophyll isolated from the living cell may still act upon carbonic acid and effect its decomposition in light. The author has therefore repeated the experiments of M. Regnard, and whilst verifying their accuracy has detected a fact which has vitiated the interpretation of these observations. The principle of Regnard's method was to bring in contact with Schützenberger's reagent (oxymetric liquor), *i.e.*, Coupier's blue decolourised by hydrosulphite, the different preparations of chlorophyll, where the question was to establish the emission of oxygen on exposure to light. But Jodin finds that the reagent of itself has the property of turning blue, that is, of giving the reaction of oxygen on mere exposure to light. His experiments seem to demonstrate that the oxymetric reagent is of itself susceptible to light, and that this property should be taken into consideration when it is necessary to show a photo-chemical reaction accompanied by a liberation of oxygen.

Volatility of Oxygenous Nitriles.—L. Henry.—The proximity of oxygen and nitrogen, both entirely fixed upon carbon and forming a system CN—CO, determines a special volatility in the compounds which contain it and distinctly reduces their boiling-point.

Effluviography.—Boudet de Pàris.—With reference to the communication of M. Tommasi inserted in the *Comptes Rendus* for March 22 (vol. cii., p. 677), entitled "Effluviography, or obtaining an Image by the Effluve," the author informs the Academy that these same results were brought forward by himself on March 3rd at the Public Session of the International Society of Electricians. The text of this communication was published in full, with a reproduction of the figures in *La Lumière Electrique* for March 20.

Justus Liebig's Annalen der Chemie,
Vol. ccxxxii., Part 1.

On Certain Ethers of Hypophosphoric Acid, and on a New Method for its Production.—Dr. A. Sänger.—The author treats of the action of ethyl-iodide upon silver hypophosphate at 100°, at the ordinary temperature of dwelling-rooms, and in presence of anhydrous ether. He then describes the hyperphosphoric ethyl-, methyl-, propyl-, butyl-, and amyl-ethers, and the formation of hypophosphoric acid by the action of silver nitrate upon phosphorous acid. He determines the quantity of ammonia necessary for dissolving silver hypophosphate, describes silver phosphite and the crystalline hydrate of hypophosphoric acid, and its decomposition. In an Appendix he describes an unsuccessful attempt to prepare a penta-hydroxyl-phosphoric acid.

On Bromo-pyromucic Acids.—H. B. Hill and C. R. Sanger.—A memoir read before the American Academy of Arts and Sciences, November 12th, 1884.

Speed of Saponification.—L. Th. Reicher.—This memoir, which is a continuation of one inserted in *Annalen* (ccxxviii., p. 257), does not admit of useful abstraction, the results being given in the form of tables.

On Hypophosphoric Acid (Fourth Treatise).—Theodor Salzer.—An account of neutral magnesium hypophosphate (dimagnesium subphosphate), mono-magnesium subphosphate (acid magnesium hypophosphate), ammonium-magnesium hypophosphate, acid calcium hypophosphate, and neutral silver hypophosphate.

Indeterminate Equations used by Pebal in his Examination of Euchlorine.—L. Boltzmann.—The author holds that, on the assumptions laid down, euchlorine must be a mixture of three gases, one of which is ordinary chlorine, the second hypochloric acid, and the molecule of the third would have to consist of four atoms of oxygen, just as the molecule of ozone consists of three.

On Calculating the Observations made with Bunsen's Ice-Calorimeter—L. Boltzmann.—A mathematical paper, incapable of abridgment.

Journal de Pharmacie et de Chemie.
Series 6, Vol. xiii., No. 5, March 1, 1886.

Assay of Commercial Oxygenated Water.—A. Riche.—This paper requires the accompanying illustration.

Detection of Sulpho-conjugated Magenta and of Ordinary Magenta in Wines by means of Metallic Oxides.—P. Cazeneuve.—Noticed under the *Comptes Rendus*, in which it first appeared.

Properties of Magenta.—M. Frehse.—Already noticed.

Communication on the New Mexican Pharmacopœia.—M. Dreyer.—The only chemical facts mentioned in this memoir is the existence of pipitzahoic acid, obtained from the root of *Dumerilia alamani*, an indigenous plant belonging to the order of Compositæ; and an alkaloid erythro coralloidine, discovered by S. Rio de la Loza in the seeds of *Erythrina coralloides*, remarkable as being the only poisonous principle as yet obtained from a leguminous plant.

Action of Boric Acid and of Borax in the Human Organism, and on its Elimination.—Dr. Johanson.—Except a considerably increased diuresis, the ingestion of boric acid had generally little action. In one case only symptoms of poisoning appeared after 3·6 grms. had been taken. After the cessation of its use the reaction of boric acid was still recognised in the urine for eight days, and in one case for fifteen days.

Detection of Ergotised Rye in Flour.—M. Hilger.—Ten grms. of the flour are left in contact with 20 grms. of ether and 10 drops of dilute sulphuric acid (1 : 5) for

some hours, at an ordinary temperature, in a well-stoppered flask, with frequent agitation. The filtrate is made up to 20 c.c. with the ether which has served for washing the mass, and ten to fifteen drops of a solution of sodium carbonate, saturated in the cold, are then added. The mixture is shaken up; the colouring matter dissolves in the watery liquid, to which it gives a violet or reddish violet colour. Still better results are produced when the flour is first moistened with a few drops of a 20 per cent solution of caustic potassa. After about ten minutes we then proceed to the treatment with ether, increasing the quantity of sulphuric acid in proportion to the alkali. The farina may then be examined with the microscope, saccharifying the starch of the flour previously with extract of malt.

Moniteur Scientifique, Quesneville.
3rd Series. Vol. xvi., March, 1886.

Alkaloids derived from the Bacterian or Physiological Destruction of the Animal Tissues.—Armand Gauthier.—In this extensive memoir, read before the Academy of Medicine, the author, after a historical survey, considers first the extraction of the septic alkaloids or ptomaines, the properties and nature of the ptomaines at present known, among which we find particular mention of parvoline, hydrocollidine and collidine, neuridine, cadaverine, putrescine, saprine, and mydaline. Cadaverine, putrescine, and saprine are not poisonous. Mydaleine is a very poisonous diamine. The putrefaction of fishes yields a poison having the same composition and the same action as muscarine. Putrid cheese yields neuridine. The bacillus to which Eberth attributes typhoid fever does not produce putrefaction, but in the liquids where it has lived there is found a trace of a base which dilates the pupils, brings on diarrhœa, and proves rapidly fatal. The physiological action of these bases and their chemical action are very carefully studied. The second portion of the treatise is devoted to the physiological alkaloids or leucomaines.

The Whole Duty of the Chemist.—From *Nature*.

The Complete Duty of the Chemist.—From *Nature*, being Dr. Odling's reply to the foregoing paper.

The Institute of Chemistry.—E. Frankland.—From the Chemical News. To this paper are appended a number of letters on the subject of the Institute of Chemistry, reproduced from the Chemical News.

International Exhibition of Inventions in London.—Watson Smith.—From the *Journal of the Society of Chemical Industry*.

The Artificial Colouring-Matters applied in Industry.—A continuation of a course of six lectures delivered by Prof. Noelting at the School of Chemistry at Mulhouse.

Industrial Society of Mulhouse.—Sittings of Dec. 9, 1885.—M. Binder communicated some observations as regards the reducing and oxidising agents of the aromatic series, taking phenyl hydrazine as an instance of the former and phenylene dichlorodiimide of the latter.

Prof. Noelting communicated various researches effected in the laboratory of the Chemical School.

Sitting of Jan. 13, 1886.

M. Hofmann requested information as to the procedures used in Alsace for purifying the waste waters of dye-works. M. Briethaupt sent in a prospectus of a new antiseptic, borhydrine.

M. Rettig sent in the completion of his researches on the action of manganese bronze upon a certain number of aromatic bases.

Camille Kœchlin, in a letter to the editor, mentions that murexide, like aniline black, is affected by sulphurous acid, but is incapable of restoration to its original shade.

C. Kœchlin mentioned M. Knapp's research on the development of ultramarine in the wet way, and stated that this colour is not destroyed by concentrated sulphuric acid. He also pointed out that all organic blue colouring-matters are nitrogenous, and suggested its necessity as a component of such dyes.

M. Weber described experiments showing that antimony oxalate and oxide when recently precipitated are excellent agents for fixing tannin.

German Review.—Under this head are inserted a number of abstracts from the *Berichte*.

Patents taken in France having connection with the Chemical Arts.—A list of titles of patents for November last.

Bulletin de la Société d'Encouragement pour l'Industrie Nationale. 4th Série. Vol. i., No. 2, February, 1886.

Report delivered by Aimé Girard on behalf of the Committee of Chemical Arts on the Process of M. Delattre for Purifying the Waters which have served for Washing Wools.—Raw wools undergo two successive operations, the removal of the suint and scouring. The former of these operations, a simple steep in water, frees the wool from the more soluble part of the suint. The second process, which is performed with lyes of soap and soda crystals, removes the insoluble portion of the adhering grease and the various impurities which this grease has fixed and retains in adhesion to the textile fibre. These washing and scouring waters are very impure, and have occasioned much trouble both to manufacturers and to the municipal authorities. J. Delattre and Son convey the washing waters into a deep narrow cistern, where they deposit the sand which they contain. This sand is said to furnish an excellent manure, very rich in potash and in nitrogen. The water is then treated either with hydrochloric acid, ferric chloride, or manganese chloride to effect the separation of the fatty matters, which form a cake on the surface. After removing the fats the water is mixed with milk of lime, and is then allowed to rest so that the suspended calcareous matters may settle. From these tanks the water issues limpid, alkaline (!), and of a pale amber colour. A plan and section of the apparatus are given.

Supplementary Note on Apparatus for Elevating Corrosive Liquids.—M. River.—This paper consists of illustrations with their description.

MEETINGS FOR THE WEEK.

Monday, 19th.—Medical, 8.30.
Tuesday, 20th.—Institution of Civil Engineers, 8.
——— Pathological, 8.30.
Wednesday, 21st.—Geological, 8.
——— Meteorological, 7.
Friday, 23rd.—Quekett Club, 8.

Aniline Works, Clayton, Manchester, All newly erected, brick and slated. Eligibly situated, water free from the canal.—To be sold or let with or without the plant on very low and easy terms (a quantity of vacant land adjoining), cheap.—Address, S. Charlton, 10, Marsden Street, Manchester.

Water-Glass, or Soluble Silicates of Soda and Potash, in large or small quantities, and either solid or in solution, at ROBERT RUMNEY'S, Ardwick Chemical Works, Manchester.

FOR SALE.
Complete Set (unbound and uncut) of
THE CHEMICAL GAZETTE,
A Journal of Practical Chemistry.
17 Volumes; from November, 1842, to December, 1859.

Address, "Publisher," Chemical News Office, Boy Court, Ludgate Hill, London, E.C.

Vol. LIII. No. 1378.

ON A NEW FORM OF STEREOSCOPE.*

By A. STROH.

Although the late Sir Charles Wheatstone's beautiful invention, the stereoscope, gives the appearance of full relief or perfect solidity to photographs of objects seen by its aid, the photographs for the same must naturally be of limited dimensions, and though viewed through magnifying lenses, the images of the objects are presented to the eye on a scale far below the size of their originals.

It has therefore occurred to me, that if the magnified image of a photograph projected on a screen by the optical lantern could be made stereoscopic, a still greater resemblance to the original might be obtained.

With a view of producing such an effect, I have constructed the apparatus I will now describe, which is, however, not intended to enable a large number of persons to see the projected pictures at the same time, as in the case of dissolving views, but is at present limited to the use of two persons simultaneously. It could, however, be easily constructed so as to be available for a greater number.

The principle of the arrangement depends on the well-known effects of the persistence of vision; revolving disks are employed for alternately obscuring two pictures, projected on a screen in the same place, and at the same time interfering with the view of the observer in such a manner that only one picture is seen by the observers' right eyes, and the other by the left eyes.

Two optical lanterns are placed side by side, as for dissolving views. Two transparencies, photographed in the same manner, as if intended for an ordinary stereoscope, are placed one in each lantern, and projected on a screen in such a position that they overlap each other as nearly as possible. The picture which is intended to be seen by the right eye may be placed in the right hand lantern, and the other in the left.

Supported by suitable framework, and in the front of the two lenses of the lanterns, is a revolving disk, portions of which are cut away, so that during its revolutions it obscures the light of each lantern alternately, or, in other words, so that only one picture at a time is thrown on the screen. A continuous change from one picture to the other is thus obtained.

In the same framework, and in convenient positions for the observers, two pairs of eye holes are provided, one pair on either side of the apparatus. Behind each pair is also a rotating disk, and these disks are connected by suitable wheel-work or driving bands with the one previously mentioned, in such a way that the three disks rotate together, and at the same rate. The two last-named disks are also so cut that they will obstruct the view through the right and the left eye-holes alternately.

Finally the connection between the three disks has to be so arranged that the time of obscuring the view of the observers' right eyes or left eyes shall coincide with the time when the light is shut off from the right or left lens of the lanterns respectively.

It is obvious that by this arrangement the left eyes can only see the picture projected from the left hand lantern, and the right eyes can only see that from the right hand lantern.

The rotation of the disks must be of such a rate that the alternate flashes of the right and left pictures on the corresponding eyes follow in such rapid succession that the impression made by one flash does not diminish sensibly before the next flash on the same eye is received. The number of flashes for each eye which is required to produce an apparently continuous view, without any flickering effect, is from thirty to forty per second. As the disks are so cut as to produce two flashes for the right eyes, and two for the left in one revolution, they must consequently be kept rotating at a rate of from fifteen to twenty revolutions per second.

The rotation of the disks is effected by a driving-wheel and band, worked by a crank handle at the back of the apparatus.

The perspective effect obtained by the above arrangement is very perfect, the image of each object standing out in solid relief.

Considering that by this arrangement the two eyes never see at the same time, and that each eye views its picture after the other, it is interesting to find that the persistence of vision so completely bridges over the alternate interruptions to which it is subjected as to produce the effect of a continuous view.

An unavoidable effect resulting from this arrangement is, that by the rotation of the disks one half of the light produced by each lantern is always cut off, the higher, therefore, the illuminating power used the better is the result.

This defect is, however, I consider, counter-balanced by several advantages which this form of stereoscope possesses. Firstly, the pictures can be enlarged to such such an extent as to appear equal, or even larger than the original objects from which they were taken; and secondly, the eyes, in looking at the pictures, are not in any way subjected to strain by lenses, prisms, or reflectors, or by the difficulty which some persons experience in getting the two pictures to superpose. For each eye views its corresponding picture in exactly the same position it would see it in if it were looking at the original, since the two pictures are practically in the same place, which is not the case in any other form of stereoscope.

Although with the apparatus as here described only two persons can see the pictures at the same time, it would not be very difficult to construct it so as to be available for a greater number. The side disks above described only serve to control one pair of eye-holes each, but by making them a little larger they would serve for two pairs each, thus accommodating four observers. By increasing the number of disks, the number of observers might be increased proportionately.

* A Paper read before the Royal Society, April 1, 1886.

ON A NEW METHOD OF DETECTING BROMIDES: A CASE OF SO-CALLED "CATALYTIC ACTION."*

By H. J. H. FENTON, M.A., F.C.S., F.I.C.,
Demonstrator of Chemistry in the University of Cambridge.

In former papers it has been shown that sodium carbamate is unacted upon by sodium hypochlorite in presence of sodium hydroxide, whereas sodium hypobromite immediately decomposes it with evolution of nitrogen.

$$2CO.NH_2.ONa + 3NaBrO + 2NaOH = 2CO(ONa)_2 + 3NaBr + 3OH_2 + N_2.$$

Carbamates differ in this respect from all other substances yet studied, and the action serves to detect and estimate them in presence of urea, ammonia, &c.†

On adding a soluble bromide to a solution of sodium carbamate, mixed with sodium hypochlorite and hydroxide, nitrogen is evolved. If this is due to the intermediate formation of a hypobromite,‡ it was to be expected that the total amount of decomposition would be independent

* The substance of a Paper read before the Cambridge Philosophical Society, March, 1886.

† Royal Society, December, 1885.

‡ Lyons, *Pharmaceutical Record*, May, 1885.

of the mass of bromide, within wide limits, since the bromide would be reproduced in the action. This I find to be the case. Thus 0·3854 grm. of potassium bromide readily caused the evolution of 340 c.c. of nitrogen from the above mixture, and the residual solution was still strongly "active,"—*i. e.*, caused an evolution of nitrogen from fresh portions of the mixture. This quantity of bromide in the form of hypobromite could only have caused an evolution of 24 c.c. nitrogen.

The initial *rate* of decomposition, however, appears to be a function of the mass of bromide present. A preliminary experiment in this direction was made as follows:—5 c.c., 10 c.c., and 20 c.c. of a solution of potassium bromide were taken in separate tubes, and made up to the same total volume with water. The tubes were placed respectively in three vessels (A, B, C), each containing the same volume of a mixture of sodium carbamate, sodium hypochlorite in excess, and sodium hydroxide. These vessels were fitted with stoppers and delivery tubes, and the evolved nitrogen collected and measured in the ordinary way.*

The masses of bromide were therefore—

$$A : B : C :: 1 : 2 : 4,$$

those of the other substances being the same in each case. The actions were started almost simultaneously, and the evolved nitrogen read off at stated intervals.

	After 3 minutes.	6 minutes.	10 minutes.	Abt. 30 m.
A gave	10 c.c. N	40 c.c.	51 c.c.	67 c.c.
B „	39	51	57	68·5
C „	55	59	62	68

Showing that the action is, in the first instance, more rapid as the mass of bromide is greater, but that the weaker solution afterwards gains on it, and all eventually give the same final result.

This action of bromides appears therefore to belong to the type of certain so-called Catalytic actions, in which the activity of the agent is explained by an intermediate stage of little stability.

By means of this action it is easy to detect bromides in presence of unlimited quantities of chlorides, hypochlorites, &c. A solution of sodium carbamate is mixed with excess of sodium hypochlorite and caustic soda, and shaken until bubbles of nitrogen (due to traces of ammonia) cease to be evolved. The addition of a soluble bromide to this mixture will cause an evolution of gas immediately if the quantity of bromide is considerable, and more slowly with dilute solutions. When traces only of bromide have to be looked for, it is advisable to make a blank comparative test, since the slight decomposition of the carbamate solution might be misleading.

Two equal volumes of the above test solution are placed in long tubes, the suspected liquid added to one, and an equal volume of distilled water to the other. The tubes are shaken and set aside for some time (ten minutes to one hour, according to quantity of bromide). On again shaking there will be an almost inappreciable evolution of gas only from the tube containing the blank test, whilst, if bromide is present, there will be a rapid effervescence in the other. In this way it is quite easy to detect 1 part of bromine in 6000 parts of water; probably much smaller quantities would be apparent.

Iodides appear to give a slight action, but so slowly that it seems not improbably due to traces of bromide as impurity. I have not, however, succeeded in obtaining a specimen of iodide which gives no action at all.

I find that a solution of sodium carbamate may be conveniently prepared by dissolving ammonium carbamate in a strong solution of caustic soda, and allowing the mixture to stand over strong sulphuric acid under a bell-jar for one or two days:—

$$CO.NH_2.ONH_4 + NaOH = CO.NH_2.ONa + H_2O + NH_3.$$

Also, by treating ammonium carbamate with sodium hypochlorite and caustic soda,—

$$2CO.NH_2.ONH_4 + 3NaClO + 2NaOH = 2CO.NH_2.ONa + 3NaCl + 5OH_2 + N_2.$$

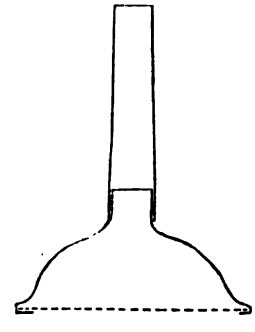
Or it may be prepared by Drechsel's method,—*i. e.*, by adding an alcoholic solution of sodium ethylate to ammonium carbamate dissolved in aqueous ammonia.

* *Chem. Soc. Journ.*, July, 1887.

A PLATINUM FILTERING BULB FOR DR. CARMICHAEL'S SYSTEM OF FILTRATION.

By P. CASAMAJOR.

Dr. Carmichael's system of filtration, first published, I believe, in 1870, is well known to all chemists. In this system filtration takes place on a small paper disc, held by the suction of a filter-pump against the flat perforated surface of a small vessel called a filtering bulb. A description of this system of filtration is given in Crookes's "Select Methods of Chemical Analysis" (London, 1886, p. 655). Chemists who have seen Dr. Carmichael perforate the flat surface of his filtering bulb by means of a hot wire say that the operation seems an easy one, but I have learned that very expert glass-blowers in New York have failed to make these perforations, so that many chemists, who would have liked to try these filtering bulbs, were not able to obtain them. Several years ago I tried Dr. Carmichael's plan very successfully, by making the filtering bulbs in two pieces, one of glass, having the shape of a Plattner's blowpipe mouthpiece, the other being a perforated platinum plate over which was placed a paper disc of slightly larger diameter. The paper disc and perforated plate were held against the glass portion by the suction



of a filter-pump. This apparatus was described in 1875 (Chemical News, vol. xxxii., p. 46; *American Chemist*, vol. v., p. 440).

In 1881 I published a description of another apparatus for Dr. Carmichael's system of filtration (*Journ. Am. Chem. Soc.*, vol. iii., p. 125).

Prof. J. P. Cooke, of Harvard, has made Dr. Carmichael's filtering bulb entirely of platinum (*Proceedings of the American Academy of Science and Art*, iv., n.s., 125). This seems the most practical and convenient way of making a filtering bulb; the shape is copied exactly from that of Dr. Carmichael's glass bulb. Only by such skill as a regular manufacturer of platinum ware possesses can Prof. Cooke's platinum bulb be made. Those he uses were made by Messrs. Johnson and Matthey, of London.

Some time ago I decided to try a Carmichael filtering bulb made entirely of platinum, and I succeeded in making it in such a way that any moderately skilful metal-spinner could construct one.

The figure represents, in section, this filtering bulb, which has given entire satisfaction. It is formed in three portions, the upper one being a straight tube, which is placed in communication with a filter-pump or its equi-

valent. This tube may be made entirely of platinum, or of platinum foil turned to form a tube, the edges of the foil being soldered with gold.

The portion immediately below this tube has the shape shown in section. No metal-spinner of ordinary skill could have any difficulty in turning it on a lathe. The platinum plate should have a thickness of not less than half a millimetre, or one-fiftieth of an inch. A flat shoulder is turned on the lower part of the bulb. Against this is placed the third portion, a perforated plate, and then the outer rim is turned over the plate so as to leave a circular margin of about 2 or 3 m.m. wide. The platinum bulb has a short tube, spun on the lathe, which is made conical so as to fit tightly into the tube which connects it with the aspirator. The bulb and tube may be soldered together with gold, if it is thought preferable, instead of being connected by the conical tube of the bulb fitting tightly into the longer tube.

The platinum filtering bulb which I am now using was made by Messrs Eimer and Amend, Third Avenue and 18th Street, New York.

ON THE DETERMINATION OF CHROME.

By H. VIGNAL.

THE gravimetric methods for separating and determining chrome are tedious, and require much care, whilst the volumetric determination of chromic acid by means of ferrous salts is expeditious in execution, and gives very exact results. The principle of this method, which has been known for some time, consists in adding to the solution of the chromic acid a known excess of iron in the ferrous state, and of determining, by means of potassium permanganate, the quantity of iron which the chromic acid has not peroxidised. The formula of the reaction shows that 6 equivalents of iron, or 168 parts, are peroxidised by 2 equivalents of chromic acid containing 2 equivalents of metallic chromium,—*i. e.*, 52·56 parts. If P represents the weight of iron peroxidised by a given solution of chromic acid, the weight of the chrome contained in this solution will be—

$$P \times 0{\cdot}313 = P \times \frac{52{\cdot}56}{168}.$$

If we determine ferrous oxide in the green solution of chromium sesquioxide, the first drop of permanganate in excess gives a dirty green tint, which should not be exceeded, for the weight of the chrome would thus be made to appear deficient. The analyst should accustom himself to catch this tint, taking for the purpose known volumes of a solution of potassium bichromate which has been determined with great accuracy gravimetrically.

We are generally apt to overstep the point of saturation a little; the error thus resulting is very trifling, but it may be corrected by substituting for the theoretic coefficient 0·313) another practical value depending on the eye of each operator. Thus, by taking 0·315 instead of 0·313, the author obtains, in known volumes of a solution of potassium bichromate, results quite accordant with those obtained gravimetrically.

To determine chromium in ores and in manufactured products it must be obtained as chromic acid in a solution free from nitrous acid, from free chlorine, and from any substance having an action upon ferrous salts. Chromium oxide in solution is more or less completely converted into chromic acid by certain oxidisers, such as lead and manganese peroxides and potassium chlorate. The latter evolves chlorine, and the liquid obtained cannot therefore serve for the direct determination of chromium.

With lead and manganese peroxides the conversion is incomplete if the proportion of chrome is somewhat high. On the contrary, when chromium oxide occurs in a strong boiling nitric or sulphuric solution, it is entirely converted into chromic acid by potassium permanganate, added either in crystals or in a strong solution. If potassium permanganate is added gradually to a solution of chrome kept very hot, this solution, if held over a white paper, appears to turn gradually from a deep yellow to a light yellow; the precipitate of manganese formed in the parts which the reagent reaches re-dissolves, either on stirring the liquid or on heating afresh, so long as the chrome is not entirely brought into the state of chromic acid; the potassium permanganate is finally converted into manganous oxide. But when all the chrome is peroxidised the first portions of permanganate in excess coming in contact with the manganous salt first formed constitute with it a higher oxide, which renders the liquid turbid, and which, after boiling for three or four minutes, collects in the form of precipitated peroxide. Instead of adding the permanganate gradually it may be introduced at once in sufficient quantity, and boiled for some minutes: in both cases the liquid contains all the chrome in the state of chromic acid, with a more or less abundant precipitate of manganese dioxide. After filtering the solution of chromic acid may then be titrated with a ferrous salt.

It may happen, especially in the case of products poor in chrome, that the permanganate is present in very large excess as compared with the chrome,—*i. e.*, after the peroxidation of the chrome, and the re-precipitation of all the manganous salt first formed in the state of manganese peroxide, there still remains in the liquid a certain quantity of permanganate. Ebullition decomposes this excess of the reagent, and precipitates it in the state of peroxide, and in this case, as in the former, the ultimate liquid contains all the chromic acid with the precipitate of manganese peroxide.

In filtering this liquid we may use either asbestos or paper. Paper filters more rapidly, but it requires certain precautions. To avoid the reduction of the chromic acid by the organic matter of the paper, it is well to moisten the filter first with hot water containing nitric acid. It is further advisable not to filter the liquid until it is quite cold and has been considerably diluted with water. If the precipitate has been obtained in a nitric solution it is flocky and filters well, but if in a sulphuric solution it is very fine and filters very badly.

In the analysis of chrome steels we have nitric liquids. For chromated cast-iron we are obliged to use sulphuric acid, but as soon as the metal is dissolved we may always add to the liquid so much nitric acid that the precipitate of manganese peroxide takes a distinct form. The precipitate is washed on the filter at first with cold and then with boiling water, until the last washings run through colourless. The washing is the more quickly completed the less bulky is the precipitate: this is why it is important to use only such a quantity of permanganate as is exactly sufficient to cause the precipitate.

The chromic solution filtered is free from nitrous products, from free chlorine, and from chlorides. It contains, indeed, nitric acid in a dilute state and colourless iron nitrate. It is mixed with a little sulphuric acid if there is none already present, and the chromic acid may then be very accurately determined with a ferrous salt. If we take known quantities of potassium bichromate, reduce it with sulphurous acid, and boil it in presence of an excess of nitric acid, observing the precautions indicated above for the addition of the permanganate and the filtration of the precipitate, the quantities of chromic acid found in the final liquid are exactly those taken.

It is seen that permanganate produces two distinct reactions: at first peroxidation of the chrome and formation of a manganous salt, and then re-oxidation of the manganous oxide and precipitation of the peroxide. Theoretically, 1·81 grms. of pure crystalline permanganate should suffice to peroxidise 1 grm. of chrome. The appearance of the precipitate indicates that the quantity of permanganate employed up to this moment is sufficient, and enables us to conclude approximately the quantity of

chrome contained in the liquid. For this purpose the permanganate is employed in the form of a strong solution, and is poured, drop by drop, from a graduated burette into the boiling liquid. The point of saturation is reached as soon as a slight brown precipitate is formed, which redissolves neither on stirring nor on boiling. The precipitate is easily recognised in the transparent liquid if the beaker is held above a piece of white paper.

It may be foreseen that this method is applicable only to products containing more than 2 to 3 per cent of chrome, and that, further, the results are always too high. In order that the precipitate of manganese peroxide may be formed in a very distinct manner, a certain excess of permanganate must always be present. To ascertain what degree of approximation may be reached by this means the author took cast-irons containing a known proportion of chrome, and used a solution of permanganate containing 18·1 grms. of the salt per litre. One c.c. of this solution should represent 1 c.grm. of chrome. For cast-irons in which the proportion ranged from 3 to 30 per cent, the mean error in excess was one-tenth of the chrome to be determined. In practice this error may be corrected either by multiplying the result by 0·90, or by using a solution of permanganante containing 20 grms. per litre.

This process, therefore, only gives approximate results; still it may be useful when it is required to follow the manufacture of chrome-irons step by step. With a little practice we may arrive at an approximation of ½ per cent.

Thus when a product can be directly dissolved in sulphuric or in nitric acid, the determination of the chrome may be effected expeditiously. Such products are chrome steels and the blast-furnace slags from the manufacture of ferro-chrome, which dissolve in nitric acid at 22° (B. ?), and, on the other hand, chromated cast-irons and ferro-chromes, which sulphuric acid dissolves very well.

The following is the course of operations for a steel:—1 grm. is dissolved in nitric acid at 22°, and 2 c grms. of permanganate are added to the hot liquid, or else 1 c.c. of the solution at 20 grms. per litre. This quantity is sufficient if the proportion of chrome is less than 1 per cent. The whole is boiled for three or four minutes; the solution is then let cool, diluted, and filtered.

For a slag the series of operations is the same. After dissolving it in nitric acid the quantity of permanganate which is judged sufficient, according to the probable amount of chrome, is added at the rate of 2 c.grms. per unit per cent. In filtering the precipitate, which is mixed with gelatinous silica, it is well to proceed by decantation.

The chrome-irons and ferro-chromes are not attacked by nitric acid. They dissolve, on the other hand, in less than an hour in sulphuric acid diluted with 3 volumes of water; ½ a grm. is dissolved at a gentle boil in 15 c.c. of water and 5 c.c. of sulphuric acid. When the reaction is over we add cautiously 25 to 30 c.c. of nitric acid at 36°, boiling for a moment to complete the peroxidation of the iron and to expel nitrous vapours; the permanganate is then added, either in solution or in crystals. If we use the solution at 20 grms. per litre we obtain at once the approximate percentage. To obtain an exact result it is necessary to filter and to determine the chromic acid in the liquid with a ferrous salt.

The chief difficulty in the analysis of chrome ores lies in the slowness with which they are opened up by chemical agents. Most commonly they are fused with caustic potash and potassium nitrate in a silver crucible, or with sodium carbonate and potassium nitrate in a platinum crucible. The latter method gives the better results, but care must be taken not to use too large proportions of alkalies, since the mixture flows like water, and the ore, falling to the bottom, is attacked very imperfectly. An intimate mixture is made of 1 part of the ore in very fine powder, with 1 part sodium carbonate and 1 part potassium nitrate, both finely ground. The mixture introduced into a platinum crucible should only occupy a small part of its bulk. The crucible is introduced into a muffle heated to redness, taking care to place it upon a cold potsherd so that it may not be heated too suddenly, and it is then left for an hour. The melted mass is taken up in water; the soluble portion contains merely chrome in the state of chromic acid, and is determined with a ferrous salt. The insoluble portion contains all the silica, alumina, and the other matters which constitute the ore. This portion, dissolved in hydrochloric acid, is treated like the hydrochloric solution of an ordinary iron-ore. It is easy to discover in this hydrochloric solution any particles of ore not opened up, and to separate these particles by decantation, either in order to weigh them or to submit them to a new attack.—*Bull. de la Soc. Chim. de Paris*, xlv., 171.

ON THE

SEPARATION AND DETERMINATION OF COPPER, CADMIUM, ZINC, NICKEL, COBALT, MANGANESE, AND IRON.

By AD. CARNOT.

AFTER having shown how, by means of ammonium or sodium hyposulphate, we may separate copper from cadmium, and the latter from zinc, the author indicates in what manner he effects the separation of zinc, nickel, and cobalt, manganese, and lastly iron, by means of sulphuretted hydrogen, modifying the condition of the liquids for the successive precipitations.

Zinc may be precipitated alone in the state of a very white sulphide by neutralising the solution entirely with ammonia, acidifying slightly with oxalic acid and passing in a rapid current of hydrogen sulphide. The liquid should be dilute and cold to prevent the formation of a deposit of zinc oxalate or of other metallic oxalates. The precipitate formed comprises the total zinc which may be determined as zinc sulphide after ignition in dry hydrogen sulphide.

If the solution from which the zinc has been eliminated contains merely nickel or cobalt, a little ammonia is added and some ammonia hydrosulphate. After digestion for a few minutes it is acidified with acetic acid, raised to a boil, and the nickel or cobalt sulphide is then collected on a filter. But it is necessary to ascertain if the precipitation is complete, by trying if the filtrate is not coloured brown or black when treated with ammonia and ammonium hydrosulphate. If there is a colouration it is necessary to decompose the hydrosulphate again with acetic acid at a boil. The precipitate is brought to the composition NiS or CoS by ignition in a Rosé crucible, traversed first by a current of hydrogen sulphide, and then by one of pure hydrogen.

If the solution contains only iron it is simply precipitated with ammonia and hydrosulphate.

If nickel and iron are simultaneously present the two metals may be precipitated and weighed together as monosulphides, by operating in the same manner as for nickel alone, or as it is indicated below.

Lastly, if after the elimination of the zinc the liquid still contains nickel, iron, and manganese, these three metals are separated by neutralising the feebly oxalic liquid with ammonia, adding an excess of neutral ammonium or sodium acetate, acidifying again slightly with acetic acid and passing in a solution of hydrogen sulphide for a very long time, then stoppering the bottle and letting the black precipitate of nickel and iron sulphides deposit. The filtrate, mixed with ammonia and hydrosulphate, gives a rose-coloured precipitate of manganese sulphide, perfectly free from other metals. On ignition in hydrogen sulphide it yields the green sulphide, MnS, of a perfectly definite composition.

The same process, consisting in the employment of

hydrogen sulphide in large excess in a slightly acetic solution, effects a very distinct separation of iron and manganese. It may be applied under various circumstances, and is sometimes preferable to the method with acetates at a boil, for this method is not perfect if the quantity of iron is considerable.

In the same case the separation of iron and zinc is effected incompletely by ammonia alone and even by the acetates. It succeeds better by the method with sulphides on condition of observing the following precautions:—Almost exact neutralisation with ammonia; dilution with much water; addition of ammonium chloride and only a small quantity of ammonium oxalate, so as not to have a deposit of iron oxalate, which would mix with the zinc sulphides and give it a black colour after ignition in hydrogen sulphide. If this accident occurs it must be calcined in pure hydrogen before weighing; then account must be taken of the sulphide FeS on re-dissolving in *aqua regia* and precipitating the small quantity of iron which has been entangled in the zinc with ammonia.

Thanks to the methods thus explained the analysis of the manifold alloys containing copper, zinc, nickel, and sometimes cobalt, manganese, and iron, the analysis of the cadmiferous, cupriferous, and ferruginous zinc ores, and that of the products of their metallurgical treatment, will become much easier and more simple than heretofore. —*Comptes Rendus*, cii., p. 678.

MANUFACTURE OF MINERAL COLOURS IN THE UNITED STATES.

THE following particulars, taken from the "Report of the United States' Geological Survey on the Mineral Resources of the States," have been forwarded to us by the author, Dr. Marcus Benjamin, F.C.S.

There are in the States 31 white-lead works, in all of which the so-called Dutch method is followed, the material used being pig-lead. The total produce during the year 1884 was about 65,000 tons.

A "sublimed lead" is made in Missouri by the direct oxidation of galena in a reverberatory furnace.

Zinc-white was manufactured in the same year to the extent of 12,000 to 15,000 tons. It is used not only as a colour but in the manufacture of india-rubber, in pottery, and in the paper trade.

Barium sulphate (heavy spar) was raised to between 25,000 and 30,000 tons. Barium compounds are used as paints under the names of blanc fixe, satin-white, &c., and in the form of peroxide for bleaching purposes. Barium sulphate, both the natural and the precipitated, is largely used as an adulterant.

Terra alba (ground gypsum) is imported from Nova Scotia, whilst a superior quality is brought from France. In addition to its legitimate use in making white pigments of a low grade it serves for adulterating a variety of commercial articles.

The quantity of red-lead produced in the United States could not be ascertained, but the imports at New York amounted to 198,588 lbs.

The American production of litharge is also an unknown quantity. The imports were only 54,183 lbs.

Concerning ochres it is said that with the possible exception of the deposits recently opened up near St. Louis, the American production is inferior to the imported qualities. "American ochres for the most part lack strength or tinting properties and require too much oil for grinding." The annual consumption in the United States is estimated at 10,000 tons, of which about 3000 tons are imported.

American umbers are inferior to those imported from Italy and Turkey. Siennas are found to a small extent in Virginia and Pennsylvania, but most of that used is imported from Italy.

There is no mention of lapis lazuli having been found in the United States, but there are two American manufactories of artificial ultramarine with a yearly output of 1400 tons.

Ground slate is used as a pigment to the extent of 2000 tons yearly, and occurs in four colours—green, red, slate, and drab.

SUGGESTIONS AS TO THE CAUSE OF THE PERIODIC LAW, AND THE NATURE OF THE CHEMICAL ELEMENTS.*

By THOS. CARNELLEY, D.Sc.,
Professor of Chemistry in University College, Dundee.

(Concluded from p. 186.)

General Conclusions.

A CAREFUL consideration of the points submitted above leads almost irresistibly to the conclusion *that the elements as a whole are analogous to the hydrocarbon radicles.* This is a conclusion which, if true, would further lead us to infer *that the elements are not elements in the strict sense of the term, but are in fact compound radicles, made up of* AT LEAST *two simple elements*, A *and* B.†

Generally speaking the elements, as I have endeavoured to show above, are analogous to hydrocarbon radicles, but differing from them in certain points, these differences depending most probably on the difference in the nature of one or more of the primary elements in the two cases. In making this analogy carbon and hydrogen are supposed to be primary elements.

Supposed Genesis of the Elements.

From the above point of view it should be possible to build up a series of compounds of two primary elements, A and B, corresponding to the—at present—so called elements. Such a system should fulfil the following conditions:—

(1.) The secondary elements generated from the two primary elements, A and B, must be capable of division into series and groups,—that is to say, they must exhibit the phenomenon of periodicity.

(2.) The several series must run in octaves.

(3.) The system must exhibit some feature corresponding to "odd and even series."

(4.) The atomic weights must increase across the system from the first to the seventh group,—*i.e.*, from the positive to the negative end of each series.

(5.) The atomicity (*i.e.*, valency) must increase from the first to the fourth or middle group, and then either increase or diminish to the seventh group.

6. It should exhibit some feature corresponding to the eighth group in Mendeljeff's classification of the elements.

(7.) The atomic weights in such a system should coincide with, or approximate to, the commonly received atomic weights of the elements.

Though up to the present I have not been able to draw out a system which will rigorously accord with all the above conditions, still the one given in the lower half of Diagram VI.‡ fulfils all except the last. This condition is indeed the most important and crucial, but nevertheless the system proposed gives atomic weights which, with but few exceptions, approximate closely to those usually taken as the true atomic weights.

* A Paper read before the British Association, Aberdeen Meeting.

† If composed of more than two simple elements, it is probable that such primary elements will be but few in number.

‡ The *upper* part of this diagram is, with one or two slight modifications, identical with that proposed by Bayley (*Phil. Mag.* (5), 13, 26

Of the atomic weights represented by this system—

27 agree almost exactly with the actual numbers.
19 are not more than 1 unit out.
5 ,, ,, 1·5 units out.
6 ,, ,, 2 ,,
3 ,, ,, 3 ,,
1 (viz., Sb) is 5·8 units out.

61 = Total.

Ag, Au, and Te are not included in the above, because the positions of Ag and Au are not known with certainty, for they may belong either to Group VIII., in which case the calculated numbers would be correct, or to Group I. (IX.), for which positions the calculated numbers are about 2 units too high. As regards Te, there are two numbers which claim to represent its atomic weight, viz., 125 (Brauner) and 128 (Wills, Berzelius, &c.), of which the former is most probably the true one.

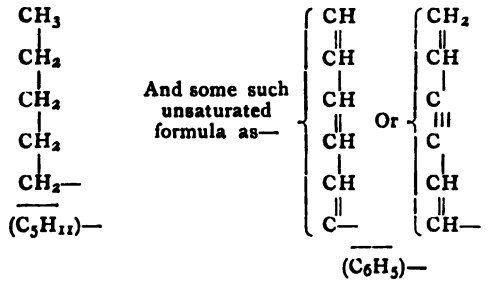
The similarity between the upper and lower parts of the Diagram VI. is strikingly illustrated by the *differences* between the atomic weights of successive periods.

With regard to the *structure* of the system represented in the lower half of the diagram the following remarks are necessary :—

First. The binary elements of this system (except Ti, V, Cr, and Mn, the general formula for which would be $A_nB_{2n+(4-x)}$) may all be represented by the general formula $A_nB_{2n+(2-x)}$, in which A = 12 and B = −2, whilst x = the group and n the homologous series to which any element belongs. A is supposed to be a tetrad element identical with carbon, and B a monad element.

Second. As represented in the diagram the atomic weights are all *even integers*. This is due to the value for B, which, for the sake of simplicity, has been taken as = −2; whereas, if the theory be correct, if should have a value somewhere between −1·99 and −2·00. Such a value would, on the whole, bring the calculated atomic weights more into accord with the actual numbers.

Third. The difference between what are commonly called odd and even series is indicated by the diagram to be due to the several series beginning with K, Rb, Cs, &c., consisting of *saturated* binary elements, whereas the series beginning with Cu, Ag, Au,* &c., consist of *unsaturated* binary elements. Thus the difference between K, on the one hand, and Cu on the other, is analogous to the difference between some such saturated formula as—



Fourth. If A = 12, then Nitrogen = AB_{-1} = 14
Oxygen = AB_{-2} = 16
and Fluorine = AB_{-3} = 18.

Now if A be really a primary element, and therefore indivisible, it would be impossible to take B from it, as indicated by the formula AB_{-1} for N, and the two following formulæ for O and F. This difficulty would, however, be removed by substituting DB_4 for A throughout the whole scheme, D being a heptavalent element of atomic weight = 20. By this substitution neither the atomic weights nor the general structure of the diagram would be affected.

Fifth. If there be any truth in the above speculation as to the genesis of the chemical elements, then the existence of elements of *identical atomic weights*, and isomeric with one another, would be possible. May not Ni and Co, Ru and Rh, Os and Ir, and some of the rare earth metals, be isomers in this sense? If this be so, it would remove one of the principal objections which have been raised against the truth of the Periodic Law.*

Sixth. In the scheme represented in Diagram VI. the chemical elements are all (except hydrogen) supposed to be composed of two simpler elements, viz., A = 20, and B = −2. Of these A is identical with the element carbon, whilst B is a substance of negative weight, possibly the ethereal fluid of space?

Supposing the theory advanced above to be true, then it is interesting to observe—

That whereas the hydrocarbons are compounds of carbon and hydrogen, the chemical elements would be compounds of carbon with ether (atomic weight = −2), the two sets of bodies being generated in an exactly analogous manner from their respective elements. There would hence be three primitive elements, viz., carbon, hydrogen, and ether.

Truly this is a bold, though most interesting, speculation,† and one which would need very ample confirmation—and no doubt some considerable modification—before it could be generally accepted by chemists. It is offered simply as a speculation, with the object of indicating new lines in which research is required, and as possibly throwing some light, however dim, on the cause of the Periodic Law and the nature of the chemical elements.

* Assuming that these metals belong to Group I. (IX.).

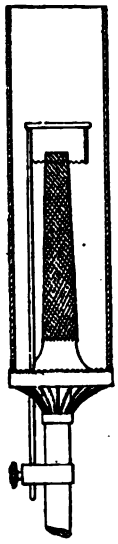
DR. AUER'S INCANDESCENT GAS-BURNER.

In the *Journal of Gas Lighting* for February 16 last (p. 302), a few particulars, extracted from the *Journal für Gasbeleuchtung*, were given of the new incandescent gas-burner invented by Dr. Auer, of Vienna; and it may be remembered that our contemporary awaited further information respecting the burner before pronouncing definitely as to its value. As the publication in question has not since referred to the subject, it is to be presumed that the desired information has not been obtained. We are enabled, however, to supplement the account of the new light which has already appeared in our columns by the following additional particulars, for which we are indebted to the last number of the *Journal des Usines à Gaz*, whence the annexed diagram has been copied. The apparatus consists simply of an ordinary Bunsen burner, above which is suspended a conical cylinder, formed of specially prepared cotton or woollen fabric, about 2½ inches high. This cylinder, as will be seen, is supported by a thread of platinum, which runs through its upper part, and is attached to two iron rods connected at the top to a ring. The longer of these rods is mounted upon a metal ring or collar encircling the stem of the burner, and adjustable by means of a screw. When the burner is lighted, there is considerable development of heat within the cylinder, which in a few seconds is raised to incandescence, producing a remarkably steady and brilliant white light. Nothing is said, however, as to the actual illuminating power (as tested by the photometer) obtained from this glowing cone; and this is a matter on which some figures will be awaited with interest. As to the material of which the cylinder is composed, it appears, according to the specification of Dr. Auer's French patent,

* In this connection compare the article on the Decomposition of Didymium, by Welsbach, in *Nature*, xxxii., 435; also Chemical News, 1885

† I have dealt with the question entirely from my own point of view, but there are many other circumstances which might be adduced in favour of the compound nature of the elements, including the results obtained by Abney (*Proc. Roy. Soc*, xxxi., 416; *Journ. Chem. Soc.*, xlii., 131) in regard to the infra-red absorption-spectra of certain carbon compounds, and the arguments advanced some time ago by Lockyer and others.

to be either oxide of lanthanium and zirconium, or oxide of yttrium and zirconium. The latter may be replaced by a quantity of erbium free from other elements belonging to this group of rare oxides; and the former, by oxides whereof the elements belong to the group of rare earths which are found in cerite. Further, the zirconium may be entirely or partially replaced by magnesia. In the formation of the cylinder, the cotton or woollen material is plaited into the required cone shape, and impregnated with a solution of nitrate or acetate of one of the before-mentioned substances; and the tissue having been carbonised, there is left behind, as residue, the earthy matter



in the form originally given to the tissue. Consequently, without any special manipulation being required, the burner may be supplied with its incandescent material. Dr. Auer does not confine himself to the cone-shaped cylinder: but in the event of other forms being adopted, he advises that the more exposed parts of the material should be strengthened by a solution of nitrate of magnesia and alumina. Such is briefly the new incandescent gas-light which it has been stated is to effect a complete revolution in the gas industry.—*Journal of Gas Lighting.*

ANALYSES OF COMMERCIAL FERTILISERS.*

(Continued from p. 188.)

PROF. H. W. WILEY said, on behalf of the committee, in presenting this report:—

Mr. President, your committee, after having carefully considered the results of the analytical work done on the samples of fertilisers furnished by it to the members of this Association, have concluded that the plan recommended by the committee at Philadelphia, with a few modifications, should be continued during the coming year. The chief alterations which we propose, you will already have noticed, are the following:—

(1) We recommend the abandonment of the use of hydrochloric acid in the preliminary digestion of the sample. All the potash salts in fertilisers which are likely to be of any use whatever to the growing plant are soluble in water, unless it be in the few cases, such as ground tobacco stems, cotton-seed hulls, &c., where we recommend a preliminary incineration with sulphuric acid. This will leave the potash in the form of sulphates readily soluble in water. We consider the preliminary use of hydrochloric acid as prejudicial. In the subsequent addition of barium hydrate the first portions of it are consumed in neutralising the free hydrochloric acid present, and thus an amount of barium chloride is found in solution which will require a corresponding amount of ammonium carbonate afterwards to precipitate. As is well known, the precipitates of barium salts carried down with them traces of the potassium. It is true that the amount of potassium thus lost is not great, yet every method should be used which is possible to make it a minimum. It is for this reason, also, that the addition of barium chloride and of barium hydrate and of ammonium carbonate should be made, as indicated in the report of the committee, drop by drop, and in as slight excess as possible.

(2) The object of the recommendation to add a little oxalic acid or oxalate of ammonium is to facilitate the conversion of any nitrates of potash which may be present into carbonates on subsequent evaporation and ignition. By this means it appears to the committee that a single evaporation and ignition of the sample will be sufficient, and hence they have recommended that the second one, as proposed in the Philadelphia method, be abandoned. Subsequently, before the addition of the platinic chloride, we add two drops of hydrochloric acid, in order to convert any carbonates which may have been formed by the above process into chlorides.

(3) As will be seen in the report of the committee, numerous experiments show that the weight of K_2PtCl_6 obtained, in the first instance, when the processes have been properly performed, is an entirely sufficient basis for the calculation of the percentage of potash present. Hence there seems to be no necessity for washing out the double chloride with hot water and re-weighing, or for the reduction of the platinum in a current of hydrogen, washing out the potassium chloride, and re-weighing the metallic platinum.

In respect of the factor to be emp'oyed, the committee do not feel warranted in recommending a change; they recommend, however, that the factor based on the new atomic weight of platinum, as determined by Seubert, be given a thorough trial during the coming year, and the results be reported to the Association at its next annual meeting.

Dr. JENKINS said, referring to the Potash Committee's report:—

The recommendation of the committee to dissolve potash in fertilisers without the use of acid is, I believe, very wise.

If acid is used in the extractive, there is a temptation, which some manufacturers have been unable to resist, to put in greensand marl, which may contain as much as 8 per cent of potash quite insoluble in water, and probably not readily available by plants. I believe no special precaution is necessary to separate N_2O_5 before making a potash determination, because most, if not all, is expelled in the usual method of procedure, as the following trials show: Two fertilisers having 2·96 and 1·38 per cent of nitrogen in the form of N_2O_5 were treated as for the determination of K_2O, but instead of adding platinum chloride the concentrated solution was tested for N_2O_5 with negative results. 0·05 grm. of KNO_3 was dissolved in water, NH_4Cl and $(NH_4)_2Cl_3$ were added, evaporated, and ignited.

The residue contained no N_2O_5.

25 grms. of $NaNO_3$ with 1¼ equivalents of NH_4Cl (0·888 grms.) in solution was evaporated and ignited. In the residue was found chlorine equivalent to 96 per cent of the nitrogen originally present which had been displaced by it.

A sample of acid rock had sufficient KNO_3 added to it to give 6·45 per cent of N_2O_5 and 12·64 per cent of K_2O. Taking no special precautions, on account of the nitric acid present, a determination showed 12·72 of K_2O.

* From the *Proceedings* of the Second Annual Meeting of the Association of Official Agricultural Chemists, at Washington, D.C., September 1, 1885. Edited by Charles W. Dabney, Jun., Ph.D. North Carolina Agricultural Experiment Station, Secretary.

Mr. GLADDING then read the following paper, which was ordered to be spread on the minutes :—

On the Estimation of Potash.

The standard method of estimating potash consists in evaporating the solution, which must contain the potash in the form of chloride, with excess of $PtCl_4$ solution, nearly to dryness, washing the residue with strong alcohol, and weighing as K_2PtCl_6.

A strongly advocated modification of the above is the method of Tatlock, the main feature of which is a preliminary washing with 2 or 3 c.c. of a strong platinum solution and final washing with alcohol. This method has the great advantage of estimating potash directly, whether in the form of chloride, sulphate, or nitrate.

In all the published experiments on the standard method we find a tendency to high results. Even when chemically pure KCl and NaCl are used without a mixture of other salts, and when the platinum solution has been refined to the utmost purity, this tendency to excess is recognised.

Thus Fresenius, in order to insure removal of all NaCl after washing with alcohol, recommends washing a few c.c. of water and recovery of any dissolved potash salt from the washings.

The committee of the British Association finds that in case the platinum solution is in large excess the results are 5 to 6 per cent too high, and this even when chemically pure KCl alone is employed.

It is manifest that in many cases of commercial analyses where the contents of potash are unknown this large excess and consequent error cannot be avoided.

Again, it has been found that even when the platinum solution gives a blank experiment, a residue perfectly soluble in alcohol, it may, from presence of certain impurities, give results far too high when working with chemically pure KCl.

When, then, to the above considerations we add the conditions under which the process is used in commercial analysis, especially in fertiliser work, and the difficulty of removing all sulphuric acid, nitric acid, organic matter, lime, salts, &c., and obtaining a solution containing nothing but pure KCl and NaCl, the greater tendency to error is at once evident.

On the other hand, the fact that in Tatlock's method the potash can be estimated directly without removal of sulphuric or nitric acids is a strong argument in favour of its use, and were it not for the one objection—that there is a loss varying from 0 to 0·5 per cent—we should certainly prefer it to the standard method.

The labour and great care required to make an accurate potash estimation by the standard method in fertiliser analysis has led to an examination of a method proposed by Lindo,* which seems to possess all the advantages of Tatlock's method, and at the same time to be free from a tendency to low results.

Lindo made 10 analyses of a mixture of KCl with 25 per cent $MgSO_4$ and 10 per cent NaCl.

This mixture was evaporated as usual with excess of platinum solution and the precipitate washed thoroughly with alcohol as usual, until all platinum salts except the potash salt has been removed.

A half saturated water solution of NH_4Cl was shaken in a bottle with K_2PtCl_6 till saturated with the latter.

This salt is very slightly soluble in the NH_4Cl solution and only a trifling amount is taken up.

This solution was used to dissolve out any Na_2SO_4 or chloride of the same bases from the precipitate.

A final washing with alcohol removed all NH_4Cl, and the Gooch crucible contained only pure K_2PtCl_6. His results were as follows :—(See next column).

KCl taken.	Weight of precipitate.	KCl obtained.
0·46239	1·5148	100·11
0·40955	1·3404	100·02
0·42510	1·3920	100·07
0·41477	1·3597	100·18
0·45149	1·4797	100·16
0·48252	1·5805	100·10
0·44488	1·4552	99·96
0·48679	1·4244	99·66
0·48062	1·4050	99·71
0·41726	1·3649	99·96
		99·99

This proposed method was submitted to the following investigation :—

Chemically pure KCl was obtained by re-crystallising chemically pure $KClO_3$, and fusing to convert it to KCl.

0·25835 grm., if this KCl gave 0·4967 grm. AgCl, equal to 0·25836 grm. KCl.

5 c.c. of the platinum solution employed evaporated to dryness dissolved perfectly in 90 per cent alcohol.

A solution of KCl in water was now made. By weighing this solution the KCl employed in all subsequent experiments was very accurately determined. Using KCl alone, Lindo's method gave the following results :—

	KCl taken.	Weight of precipitate.	KCl obtained.
(1)	0·24618	0·80650	100·11
(2)	0·12752	0·41770	100·06
(3)	0·12395	0·40550	99·98

These analyses show that there is no tendency to loss by this method.

To test the method applied to the estimation of potash in the form of sulphate, chemically pure K_2SO_4 was employed, using an excess of platinum solution and several c.c. of HCl. The results were as follows :—

	K_2SO_4 taken.	Weight of precipitate.	K_2SO_4 obtained.
(1)	0·12539	0·8580	100·95
(2)	0·13228	0·3790	102·81
(3)	0·49780	1·4148	101·45

These results show that with HCl alone added the precipitate is not pure K_2PtCl_6. It may be that the presence of free H_2SO_4 causes the error.

To test this an amount of NaCl about equal to the K_2SO_4 was added in the following experiments, thus avoiding presence of free H_2SO_4 :—

	K_2SO_4 taken.	Weight of precipitate.	K_2SO_4 obtained.
(1)	0·134977	0·3782	100·01
(2)	0·121427	0·3415	100·16
(3)	0·122500	0·3429	99·95

The method was now applied to the estimation of potash in superphosphate, using the following mixture :—To 60 parts of an acid phosphate were added 10 parts each of the following salts : $NaNO_3$, NaCl, $MgSO_4$, and $(NH_4)_2SO_4$.

A blank experiment, using 1 grm. of this mixture, gave 0·08 per cent potash.

This amount was deducted in subsequent experiments.

Experiment 1.—One grm. + 0·07484 grm. KCl, containing 0·0478 grm. K_2O, gave 0·2464 grm. K_2PtCl_6. Taken, 4·78 per cent ; obtained, 4·75 per cent.

Experiment 2.—One grm. + 0·02748 grm. K_2SO_4, containing 0·01485 grm. K_2O, gave 0·01486 grm. K_2O. Taken, 1·485 per cent ; obtained, 1·486 per cent.

A second mixture, which was received from Dr. E. H. Jenkins, and which contained 12·62 per cent K_2O by composition, gave by this method 12·61 per cent, 12·56 per cent, 12·63 per cent.

These very satisfactory results as regards accuracy taken in connection with the far easier manipulation, have led to the adoption by our firm of the following scheme for the estimation of potash in fertilisers :—

* CHEMICAL NEWS, xliv., p. 130, note.

(1.) *Superphosphates.*—Boil 10 grms. of the fertiliser with 300 c.c. of water for ten minutes. Cool the solution, add ammonia in slight excess, thus precipitating all phosphate of lime, oxide of iron and alumina, &c., make up to 500 c.c., mix thoroughly, and filter through a dry filter; take 50 c.c., corresponding to 1 grm., evaporate nearly to dryness, add 1 c.c. of dilute H_2SO_4 (1 to 1), and evaporate to dryness and ignite to whiteness. As all the potash is in form of sulphate, no loss need be apprehended by volatilisation of potash, and a full red-heat must be used until the residue is perfectly white. This residue is dissolved in hot water plus a few drops of HCl: 5 c.c. of a solution of pure NaCl (containing 20 grms. NaCl to the litre) and an excess of platinum solution (4 c.c.) are now added, and the whole evaporated as usual. The precipitate is washed thoroughly with alcohol by decantation and on filter, as usual. The washing should be continued even after the filtrate is colourless. Ten c.c. of the NH_4Cl solution, prepared as above, are now run through the filter. These 10 c.c. will contain the bulk of the impurities, and are thrown away. A fresh portion of 10 c.c. NH_4Cl is now run through the filter several times (five or six). The filter is then washed thoroughly with chemically pure alcohol, dried, and weighed as usual. The platinum solution used contains 1 grm. metallic platinum in every 10 c.c.

(2.) *Muriates of Potash.*—In the analysis of these salts an aliquot portion containing 0·500 grm. is evaporated with 10 c.c. platinum solution plus a few drops of HCl, and washed as before.

(3.) *Sulphate of Potash, Kainite, &c.*—In the analysis of these salts an aliquot portion containing 0·500 grm. is taken, 0·250 grm. of NaCl added, plus a few drops of HCl, and the whole evaporated with 15 c.c. platinum solution. In this case special care must be taken, in the washing with alcohol, to remove all the double chloride of platinum and sodium. The washing should be continued for some time after the filtrate is colourless. 25 c.c. of the NH_4Cl solution are employed instead of 10 c.c., and the second 25 c.c. poured through at least six times to remove all sulphates and chlorides. Wash finally with alcohol, dry, and weigh as usual.

A single experiment attempting to estimate potash directly in nitrate of potash did not yield satisfactory results. In such cases it may be necessary to first evaporate to dryness with HCl, and then proceed as in analysis of muriates.

To test the solubility of K_2PtCl_6 in the NH_4Cl solution prepared as above, 3·13 grms. of finely pulverised K_2PtCl_6 were digested with 200 c.c. of the NH_4Cl solution, and filtered through a Gooch crucible. The loss was found to be 0·0002 grm.

Wherever the standard method of estimating potash is employed, the washing of the precipitate of K_2PtCl_6 with the NH_4Cl solution would undoubtedly be a valuable addition to the present process.

To prepare the washing solution of NH_4Cl, place in a bottle 500 c.c. H_2O, 100 grms. NH_4Cl; shake till dissolved. Now pulverise 5 or 10 grms. of K_2PtCl_4, put in the bottle, and shake at intervals for six or eight hours; let settle over night; then filter off liquid into a second bottle. The first bottle is then ready for a preparation of a fresh supply when needed.

Laboratory of Stillwell and Gladding.

(To be continued).

On a New System of Lighting known as Pneumatic Lighting. — M. Bender. — The fuel is not the volatile petroleum products, but the fatty residues from the rectification of crude mineral oils. There is produced an open flame like that of a gas-burner, which gives off no smoke. A current of air, laid on in pipes like gas, is passed through the oil. The advantages alleged are cheapness and immunity from explosions, but portability is sacrificed.—*Moniteur Scientifique.*

CHEMICAL NOTICES FROM FOREIGN SOURCES.

Note.—All degrees of temperature are Centigrade unless otherwise expressed.

Journal für Praktische Chemie.
New Series, Vol. xxxiii., Part 5.

Action of Paratoluidine on Resorcine and Hydroquinone.—A. Hatschek and A. Zega.—Resorcine and hydroquinone react with paratoluidine in a manner quite analogous to that of aniline under similar circumstances. If these dioxybenzols are heated with paratoluidine and calcium chloride to 260° to 270° there is formed much meta- or para-oxyphenyl-paratolylamine, and little ditolylised meta- or para-phenylendiamine.

Calorimetric Investigations.—F. Stohmann (Sixth Memoir: On the Thermic Value of Benzol).—The combustion-heat of liquid benzol is, according to Berthelot, 776,000 cal.; according to the author, 779,530 cal.; but according to Thomsen, 791,870 cal.

The Cerium Oxides in their Practical Application.—Dr. J. R. Strohecker.—The author considers the ceriferous clays as pigments and raises questions as to their possible agricultural and medicinal action.

Moniteur Scientifique, Quesneville.

On Lakmoid, Litmus, Phenolphthaleine, and other Alkalimetric Indicators. — R. Thomson. — From the Chemical News.

On Different Bleaching Agents. — G. Lunge and L. Landolt.—An examination of certain novel bleaching agents. The authors have studied the so-called "chlorozone," which they conclude is a solution of free hypochlorous acid in a solution of sodium chloride. Dr. Lunge and M. Landolt have prepared the article themselves, following literally all the directions given in the specification. They have further examined the products of the action of chlorine upon magnesia, the behaviour of chlorine with zinc hydroxide, aluminium hypochlorite, the preservation of bleaching-solutions, the conversion of chloride of lime into calcium chloride, and they have, lastly, made comparative experiments with different bleaching-agents. They find that the magnesia-liquor acts almost as slowly as that of lime, whilst the aluminium, and especially the zinc, solutions are very active. The treatment of the bleaching-liquor with a current of carbonic acid heightens its decolourising power in all cases.

On Artificial Colouring-matters applied in the Arts.—A Course of Lectures delivered by Dr. E. Noelting at the Mulhouse School of Chemistry.—In this third lecture the author treats of the derivatives of triphenylmethane.

Chemistry of Colours.—J. M. Thomson.—A lecture delivered, apparently, before the Society of Arts.

The Pleasure Voyages of M. Grawitz in Company of his Ungreenable Aniline-Black.—A humorous account of the riots at Renaix, in Belgium, in connection with the proceedings taken by a M. Grawitz to enforce a patent for ungreenable aniline-blacks. [Street-fighting seems to us an undesirable novelty in patent-litigation.]

Properties and Proprietors of Aniline-Black.—Camille Kœchlin.—The author contends that blacks developed in heat, whether in printing or dyeing, are permanent, whilst those produced below 75° turn more or less green. An ungreenable steam aniline-black was obtained by Cordillat in the very year of Lightfoot's original discovery.

A New Elementary Body, Germanium.—Already noticed.

Determination of Potassium Tartrate in Crude Argols and Lyes of Wine.—Dr. Klein.—This paper, credited to the CHEMICAL NEWS, was originally taken from the *Zeitschrift für Analytische Chemie.*

The Influence of Climate on the Flavour of Beer.—M. Velten.—In this paper, taken from the *Wochenschrift für Brauerei*, the author argues that local differences of flavour, which he fully admits, are due to different ferments present in the air and the brewery-plant, and becoming more or less mixed with the normal alcoholferment.

French Patents connected with the Chemical Arts.—A list of titles for December last.

Industrial Review and Patents.—A selection of abstracts from *Chemische Industrie*, *Dingler's Journal*, the *Chemiker Zeitung*, &c., concerning cryolite glass; the spontaneous ignition of packing materials in which bottles of nitric acid are conveyed; the action of different elements, and their oxides and sulphides, on the fixation of the halogens in organic molecules; practical applications of synthesis by means of aluminium chloride; process for the oxidation of the petroleum hydrocarbons and their analogues for their conversion into acids; proportion of pseudocumene and mesitylene in different mineral oils; preparation and uses of algine; the analysis of the commercial aniline oils; and critical observations on the last-mentioned paper.

Patents taken out in Berlin.—Abstracts of the specifications of processes for the utilisation of the acid residues from refineries of coal-tar and mineral oils; preparation of aluminium from its fluoride; preparation of benzoic sulphinide by means of sulpho-conjugated benzoic acids; preparation of a substance analogous to wax, and known as "ceroid" from the grease of wool; preparation of ortho-nitro-amido-para-methoxyl benzine and ortho-nitro-amido-para-ethoxyl benzine by the action of ammonia upon mono-nitro-dimethyl hydroquinon and mono-nitro-diethyl-hydroquinon; process for preparing a thio-para-toluidine and derived azo colouring-matters; process for preparing dry alizarine which in contact with water resumes the consistence and properties of alizarine-paste.

Academy of Medicine: On the Ptomaines, the Leucomaines, and the Microbian Theory.—Armand Gautier.—A critique of a recent memoir by M. Peter.

Fibre of China Grass.—A. Sansome.—From the *Journal of the Society of Dyers and Colourists.*

The Present Depreciation of the By-Products of the Distillation of Coal.—In this report we find a summary of matter taken from the report recently presented at the Annual Meeting of the South Metropolitan Gas Company, from a report made by Dr. Bunter to the Society of German Gas-Engineers, and from a memoir read by Mr. G. E. Davis before the London Section of the Society of Chemical Industry. It appears that coal-tar is in danger of becoming absolutely unsaleable. The demand for ammonia may possibly improve. Its rival product, Chili saltpetre, seems to have reached its minimum point in price, and the manufacturers are combining to limit production. On the other hand, the demand for ammonia is likely to increase, owing to the Solvay alkali process and its use in refrigerating-machines.

The Great Lavoisier Medal.—M. Knieder having apparently withdrawn his claims, M. Michel Perret, inventor of the stage-furnace for burning pyritic smalls, seems to be the sole candidate.

The Industrial Society of Mulhouse. Chemical Committee (Session of February 10th, 1886).

M. Weber wished to define more clearly the meaning of a phrase used in his memoir on red stains in calicos printed with aniline-black. He did not intend to say that such spots were not often caused by traces of acids remaining in the tissue, but merely that such traces were not the sole cause.

M. Rosenstiehl, in a memoir published as early as 1871, had shown that such stains were due sometimes to traces of acids, but also sometimes to the nature of the cotton used.

M. Durand wrote that the first idea of applying, in printing and dyeing, the green lakes formed by certain nitroso-phenols with the salts of iron, was due to M. Philippe Greiff, in 1882. He experimented with two nitroso-phenols and with dinitro-resorcine.

G. Schoen mentioned that in 1875 he had successfully used, in place of gum, a product known as apparatine,—a fact which may be of practical interest on account of the present high prices of gums. Apparatine is made by adding to 76 litres of water 16 kilos. of starch, stirring constantly, and then 8 kilos. of caustic soda at 25° B., stirring constantly for an hour. The thickening is recommended for light catechus used for grounds.

THE CHEMICAL NEWS.

Vol. LIII. No. 1379.

DR. KOCH'S GELATIN-PEPTONE WATER-TEST.*

By Prof. G. BISCHOF.

We have repeatedly been painfully reminded of the fact that chemical analysis may fail to indicate danger in samples of water, when it exists in its gravest form. The occasional discharge by a single man into millions of gallons is beyond the reach of chemistry, whilst the experience at Caterham and Redhill a few years ago proved that any specific virus in the discharge may be the cause of an epidemic. The search for such virus amongst the organised living matter is therefore of supreme importance, and the biological water-test proposed by Dr. Koch, opening a prospect of success in that direction, was received by many who had been engaged in the examination of water, as a delivery from the uncertainty surrounding this important branch of laboratory operations. How far has it realised our expectations?

The test gives two indications,—the number of colonies, total and liquefying, formed by the centres or microphytes contained in a sample of water, and a microscopic examination. No reference is generally made in reports to the latter. I have examined many hundred different samples, subjecting the test also to numerous experiments, and now beg leave to submit the following conclusions:—

(1.) The number of colonies agrees in most cases very closely in parallel tests of the same sample. Dr. P. Frankland and I made independent tests for three months of the total colonies in the supply of the several Metropolitan Water Companies. This embraced nearly fifty samples, with the result that we both assigned to each Company almost precisely the same place, showing the close agreement even in the hands of different operators.

(2.) In comparing different samples, those which have a like history—which therefore are in fact alike—are almost always readily recognised as such by the number of colonies; but any difference in the treatment to which samples may previously have been subjected may entirely upset all attempts to draw correct conclusions from that number. To make this clear we will suppose that water is passed from one and the same source, in an otherwise precisely like manner, through two pipes. The question arises whether an infiltration of sewage takes place into one of them, and we test samples of the water, which has passed through each pipe. If we find a like number of colonies in both, there is in all probability no such pollution. But should the pipes be subjected to different temperatures, and the water in one of them become cooler than in the other, or should there be any material difference in the time of transit in them, the conclusions drawn from the number of colonies may be misleading. We have therefore, in the first instance, to consider the conditions upon which the development of microphytes, and thereafter the number of colonies, depend.

Temperature is perhaps of the greatest influence, because development is entirely suspended near the freezing-point, and accelerated to a most extraordinary degree as gradually 30° to 40° C. are approached. From this it appears clear that, as far as the number of centres is concerned, a deep-well water with 12° C. cannot be strictly compared to a river water with, say, 2° C.

The food required by microphytes for their development is derived from all and every kind of matter of organic origin, as also from a variety of compounds of inorganic nature. The leaves which fall into a river, the natural hay-infusion carried into it in the autumn, the manure washed into it, various mineral salts derived from rocks or otherwise,—everything is their prey, and may greatly influence development. A few drops of a sterilised solution of sodic phosphate added to a sample of water will make a striking difference in the number of colonies obtained by culture; in fact we must recollect that the multiplication of microphytes is not as much limited by their power of propagation as by the conditions surrounding them. One single bacterium termo, Prof. Cohn has told us, might, under sufficiently favourable conditions, fill up the entire ocean in less than three days with its progeny.

The following experiments were made with a view of ascertaining the influence of time or storage upon the number of colonies, it being self-evident that all samples which we may test have undergone some kind of storage:—

(*a*.) New River water, which would have been styled "very good" by Dr. Koch had it even contained twice the number of colonies found, was kept for six days in my laboratory in a sterilised flask, protected against aërial contamination. The result was a gradual increase of microphytes from day to day by self-multiplication from 1 liquefying or a total of 53 colonies, to 640 liquefying or a total of 770,000 colonies per cubic centimetre. The latter figure is seventeen times in excess of the total colonies found in a sample of Thames water, which I took a few months ago at London Bridge, the liquefying colonies also comparing unfavourably. This proves the predominating influence of storage when compared even with such a relatively polluted water as that of the Thames at London Bridge.

(*b*.) After adding to the above sample of New River water 1 per cent of sewage, which had been filtered through paper, the total colonies increased almost 600 times, whilst, after keeping this mixture for six days side by side with the pure water (*a*), the colonies in the latter exceeded those in the sewage tainted water almost 20 times. This result is probably analogous to the well-known experience that, in brewing, fermentation is shortened by the addition of yeast. At all events it proves the possibility that a sample in which many less colonies have been found than in another may be the more polluted.

(*c*.) The flasks in experiment (*a*) had been protected by ordinary plugs, which are known not to give invariable security against the penetration of microphytes. To exclude the possibility of any such error a number of pieces of 1-inch glass tubing, each about 3 inches long, were drawn out at both ends to a fine point, sterilised, and filled to about one-third with a water in which 27 liquefying, or a total of 290 colonies per c.c. had been found. The ends of the capillary tubes being sealed before the blowpipe, the samples were transferred to a cultivating chamber and kept at about 18° C. After six days the liquid in one of the tubes contained—on the average of four closely agreeing tests—8400 liquefying, or a total of 21,000, colonies per c.c. The liquefying colonies were, from the beginning, largely preponderating as compared with those in the first experiment, and after culture they were 40 per cent of the total colonies against about 0·1 per cent in the first experiment. This probably is the cause of the comparatively slight increase of other colonies. After a total of twelve days' culture the colonies showed a decrease to 1300 liquefying, or a total of 6400; and after twenty-two days to 880 liquefying, or 1700 total, colonies. After forty-four days' culture the liquefying colonies had decreased to 83, the total colonies being the same as after twenty-two days, viz., 1700. The experiment is being continued.

(*d*.) I have lastly traced the influence of storage, as indicated by the number of colonies, on the water in a clean slate cistern supplying my laboratory. During the

* Paper read before the Society of Medical Officers of Health, April 16th, 1886.

recent cold weather, when the New River water feeding the cistern had a temperature of 5° C., 17 liquefying, or a total of 49, colonies were found in it, whilst the water drawn from the cistern in the usual way, which had a like temperature, showed a total of 127 colonies per c.c., but no liquefying colonies. When the supply had reached a temperature of 11° C. it contained 37 liquefying, or a total of 880, colonies, whilst the water drawn from the cistern as above, having a temperature of 11½° C, contained 12 liquefying, or a total of 1544, colonies. The liquefying colonies had therefore under the circumstances decreased in both experiments, whilst the total colonies increased two to three times. I thought it interesting to ascertain, in connection with the above experiments, the relative bacteriological purity, or rather the number of colonies, when withdrawing water from the bottom of the cistern as above, with a tap of 2 feet higher up (about 2 inches below the top level). In some instances I obtained a very considerable increase of colonies at the bottom, in others an almost like increase at the top, and again in others no practical difference between the two samples; but the liquefying colonies were always, sometimes very considerably, in excess at the top. This behaviour probably depends essentially upon currents in the water when its surface is cooled by a depression of the temperature, and upon the relative quantities of water which are withdrawn from the top and bottom. The liquefying colonies appear to be more independent, selecting the top strata, perhaps on account of the oxygen there constantly absorbed from the atmosphere. The feed water was introduced in some experiments, as usual, at the top, in others at the bottom of the cistern: in the former case, contrary to my expectation, the colonies at the top showed the greatest reduction. It may not be without importance if these indications should lead to some simple mechanical arrangement, allowing of the withdrawal from cisterns of a water containing fewer microphytes than with our present appliances, as such reduction would be likely also to extend to any specific disease germs which may have entered the water supply.

The development of microphytes is lastly influenced by the proportion of free oxygen present, and of light or darkness. We know that the enormous microscopic growth in certain waters can be checked by exclusion of light. In order to keep the influence of light distinct from that of storage, parallel samples of water were mixed in the usual way with gelatin-peptone, spread on glass plates, and cultivated with and without exposure to light. When light was excluded the total colonies were, on the average of six experiments, reduced by about one-third as compared with the samples exposed to light. A distinct excess of colonies, when cultivating in darkness, was observed in one case only.

(3.) The preceding observations have laid a foundation upon which we may build up our argument concerning the reliability of the gelatin-peptone method as a hygienic water-test. Organic carbon and nitrogen, ammonia, nitric and phosphoric acid, chlorine, and other bodies met in potable water, have all in their turn been employed as analytical standards, because they point to something, or at least are supposed to point to something, which is or may be injurious to health. *The numbers of colonies, excluding for the present specific germs of disease, can likewise claim significance only if they bear in some way an invariable, or at least practically invariable, ratio to wholesomeness.* It must either be shown that they themselves follow a like rule as chemical poisons, being harmless in some numbers and hurtful in others, or, second, that they are an indication of something else which is injurious.

Absence of colonies, which happens but rarely, may safely be taken as a sign of exceptional purity, excluding at any rate recent pollution of a sample. A few colonies probably justify a similar conclusion, but we do not know where to draw the boundary. Taking the other extreme, as many as 770,000 microphytes per c.c., and may be many more, are evidently *per se* not necessarily an indication of unwholesomeness, otherwise this would have been observed on board ship, where water frequently has to be stored much longer than six days, and under much more unfavourable conditions than in my experiment. Should this argument not satisfy anyone, I can give still another. Mix the gelatin in one of your test-tubes with sterilised water, spread on a glass plate, and expose this for an hour to the air of your laboratory. The gelatin after culture will in all probability exhibit the appearance of what is assumed to be a very inferior sample of water, both in numbers and kinds of colonies. With every breath we draw in those microphytes, and, however pure water may be, we wash them down when we drink it. This again shows the impossibility of condemning a sample simply and solely because it contains a certain number of colonies, although this may exceed more than a thousand times the number ordinarily found in potable water. On the other hand, it is equally impossible to mark 770,000 colonies per c.c. as permissible, though specific germs of disease may be absent, for this would mean, as we have seen, that Thames water from London Bridge, or a sample actually mixed with 1 per cent of sewage, is, as far as bacteriological purity goes, very considerably within the boundary.

But the number of colonies ordinarily found in cultured samples of water may perhaps be an indirect indication of danger, being in some ratio to the liability of the introduction of pathogenic microphytes by polluting matter. Let us, then, enquire whether some of the conditions, at least, upon which we found the development of microphytes to depend, have an invariable connection with pollution.

Temperature, storage, and light have obviously no such connection whatever. Highly polluted waters are, as a rule, not as well aërated as pure waters; but if the deficiency of oxygen has, under the circumstances, at all an influence on the development of microphytes, it would check it. We would therefore find fewer colonies in a highly polluted water, or the reverse of what we ought to arouse our suspicion. Food, the only remaining link to establish a connection between the number of colonies and pollution, is unquestionably the result of the latter in the widest sense, but let me remind you that even the scanty traces of food in distilled water suffice sometimes for the development of comparatively very large numbers of microphytes. Practically speaking there is in this case no pollution whatever, and, going a step further, the "very good" sample of New River water contained a sufficiency of food for at all events as many as 770,000 colonies per c.c. If we take that quantity of food as an indication of so serious a pollution that we must condemn the sample, very few potable waters will remain which have not to be condemned, or, if we pass it over as insignificant, very few will not pass muster. How, then, are we to proceed? No doubt the number of colonies and food or pollution bear, perhaps in the majority of cases, a direct ratio to each other, but we have no means of knowing whether or not this holds good in any given case.

(4.) Although we may be unable to accept the number of colonies, in testing water indiscriminately, as the standard of either wholesomeness or pollution, that number may in a variety of enquiries give most useful and reliable indications, if applied judiciously. Some such instances have already been referred to, and they could be largely multiplied. But even in such a simple experiment as the purification effected by some filtering material, it is conceivable that the number of colonies found may largely be due not to a deficiency in the action of the material, but to its power of retaining water. It is not easy, under any circumstances, so to wash a filtering body that every trace of the water added, say, on starting the experiment, has been renewed. Unless the material is absolutely antiseptic throughout, any microphytes in the water so retained would at once start a multiplication

similar to that in the New River water kept for some days.

The flow of water supplies an abundance of food, and, a portion of the progeny being carried along with it, the filtered water may compare unfavourably as regards numbers of colonies, and yet these may be of as little significance as in those samples of New River water. Here, again, absence of colonies in the filtered water, or a very great reduction, give more conclusive indications than an increase.

If I as a chemist may venture to express an opinion on a purely biological subject, I would further mention that the vitality of some microphytes is apparently increased by the separation of others. The lowest forms of organisms have amongst themselves the same fight for supremacy, or existence, which we find amongst the highest. This is indicated by the experience of M. Pasteur, that the virus of hydrophobia loses its virulence when decomposition sets in. Dr. Koch is of opinion that bacteria of putrefaction may likewise exterminate the comma bacillus; and Prof. Arnaldo Cantani has had experience tending to show that inhalations of a rich culture of bacterium termo in gelatin are destructive to the tubercle bacillus. In this way considerable complications may arise, if we attempt to draw conclusions from the number of colonies, for, speaking under the correction of the specialists here present, the conqueror—if I may use that term—may be more prolific than the conquered microphyte. In that case a separation of the one can actually result in an increase of colonies; and if we assume, as in the above instances, that the conqueror is harmless, the conquered microphyte hurtful, such increase would mean an important sanitary improvement of the water.

(5.) A careful and systematic microscopic examination of the colonies found, which is scarcely within the province of a chemist, is an important aid in drawing conclusions from their numbers. Such examination is, however, incomplete without pure culture of the colonies in appropriate media. The controversy about the identity of Dr. Koch's comma bacillus is fresh in the memory of all who take an interest in such matters. Dr. Koch has told us that a precisely similar microphyte, as far as appearance under the microscope goes, was mistaken for the comma bacillus, and that the two can only be distinguished by the application of *three tests*, viz., the microscopic examination, and culture both in gelatin and on potatoes. This surely does not apply only to the comma bacillus, but also, more or less, to other microphytes, and the reliability of our conclusions appears the more diminished the less of the colonies present, in proportion to the total, can in the course of ordinary laboratory work be subjected to such rigorous tests. In extraordinary emergencies—say during an epidemic—hundreds, or even thousands, of colonies may be scrutinised by a staff of experts in the examination of a water; but even if all this has been done, I ask you, is our knowledge of the pathogenic microphytes, which are the cause of zymotic disease, sufficiently advanced to make sure that we may not pass over a culprit as harmless? The picking out by chance of some pathogenic microphyte would be important, but can scarcely satisfy the demands of hygiene, for amongst hundreds of harmless colonies a hurtful one of similar appearance may escape notice. Those pathogenic microphytes which cannot be cultivated in gelatin-peptone are entirely lost to observation, unless other cultivating media be employed. Another difficulty which occurred to me is, that the microscopes at present in use do not reach a large portion of the inner field of the cultivated plates. There important colonies may escape detection, and it seems desirable either so to alter the microscopes or the glass plates that the whole field of the latter can be scrutinised. Dr. Koch considers that the suspicion attaching to the numbers of colonies is enhanced if many different *kinds* are present, but I have not seen a single report containing a reference to this criterion, nor do I know how to apply it. It is not unfrequent that not even the numbers of liquefying, but only those of the total colonies are given.

(6.) The difficulties pointed out above would largely disappear if means or conditions could be suggested allowing of culture of pathogenic microphytes, more or less to the exclusion of others. For instance, some probably harmless microphytes do not thrive without light, whilst pathogenic microphytes cannot be dependent upon light, or the animal body would not be their favourite nidus. I have therefore proposed to Dr. Koch that it might be useful to take advantage of my experience herein referred to, and lay down the rule that all cultures in testing water be made with exclusion of light.

I confess I am one of those who based very sanguine expectations on the gelatin test, which I hoped would prove an important aid in the work I am engaged in. Great is my disappointment in finding myself unable to trust to it implicitly, the greater as I thus find myself in opposition to a man whose achievements in hygienic research stand as high as those of Dr. Koch. But were his time and thought not more than fully taken up by pathological work of the greatest importance to mankind, I feel assured he would long ago have advanced the same line of argument which I—I am afraid in a very imperfect manner—have placed before you this evening. As it is, I must draw the conclusion that the number of colonies ordinarily found in water has no necessary or invariable connection with wholesomeness or pollution. Such a connection may or may not exist in any given case, and we have no means of deciding whether the one or the other applies. The detection of pathogenic microphytes by microscopic tests, including pure cultures, would be of great importance, but is limited by our knowledge of those microphytes. In fact, although the test is most useful in special cases, I am of opinion that it requires development at the hands of biologists and pathologists before chemists can attempt to draw from it generally applicable conclusions. I have extended my enquiries for many months to regular reports on the Metropolitan water-supply, but unless fallacy can be pointed out in my experiments and arguments, which would give me the greatest satisfaction, I do not think it would serve any useful purpose to further continue them.

ON THE EXPLOSION OF HOMOGENEOUS GASEOUS MIXTURES.

By DUGALD CLERK, F.C.S.

EXPERIMENTS were made by Hirn in 1861 to determine the pressures produced by the explosion of mixtures of inflammable gases with atmospheric air. The pressures of the explosions were much lower than calculation gave, assuming that the maximum pressure of the explosion was coincident with the complete combustion of the gas. For a mixture of 1 volume of hydrogen and 9 volumes of air, calculation gave 5·8 atmospheres, whereas experiment only showed 3·25 atmospheres. Coal-gas behaved in a similar way. Bunsen's experiments, made in 1866, corroborated Hirn's results, and went a step further by proving that the heat was not all evolved, even when the vessel was completely filled with flame; that was, the deficiency of pressure was not due to the burning out of the flame at one part before ignition occurred in the other part of the vessel. More recently a series of papers had appeared describing numerous experiments by Messrs. Mallard and Le Chatelier, in all of which experiments a large deficiency of pressure was observed. Messrs. Berthelot and Vieille also supported their conclusions.

* A Paper read before the Institution of Civil Engineers, March 9, 1886.

The author had made the experiments described in this Paper, partly to obtain much-needed data for gas-engine work, and partly to study more fully the nature of the actions occurring during explosion. His experiments corroborated those of previous workers, in proving indisputably the existence of the limit to increase in pressure, the deficiency in pressure being very great, seldom more than one-half the heat of the explosion being evolved at the moment of maximum pressure. The explosion-vessel used by the author was a strong cast-iron cylinder, the internal space being 7 inches in diameter and 8¼ inches long. Upon the upper cover was mounted a Richards' indicator, from which the ordinary reciprocating-drum had been removed and a revolving one substituted, driven by a falling weight and suitable gear; a fan moving at a high velocity served as governor. The revolving-drum was enamelled, and a soft blacklead pencil, held by the indicator motion, marked upon it a line caused by the movement of the indicator piston. A pair of insulated points projected through a plug in the bottom cover and served to ignite the mixture when a spark from a coil and battery was passed between them. The line traced on the drum by the indicater showed the amount of rise in pressure, and the times of rise and fall in terms of revolution of the drum. The tracing was precisely analogous to the indicated diagram from an engine. The rising line was due to the explosion, the falling line was due to the cooling action of the cold walls upon the hot gases. The tracing was in fact a record of the rapidity, intensity, and duration of an explosion. Careful tracings were made, which were reproduced. Tables were given of the results obtained from various mixtures of air with Glasgow coal-gas, Oldham coal-gas, and pure hydrogen.

Glasgow Coal-Gas- and Air-Mixtures.

Temperature of Gas before ignition 18° C. pressure, atmospheric (14·7 lbs)

a	1/7	41	826 to 909	0·15
b	1/5	68	1358 ,, 1539	0·026
c	1/4	80	1615 ,, 1929	0·01

From these experiments the relative value of the different mixtures of gases for producing power might be calculated. In Glasgow-gas, the most economical mixture for non-compressive engines was 1 volume of gas to 11 volumes of air; Oldham-gas 1 volume of gas to 12 volumes of air. Comparing Glasgow-gas and Oldham-gas, the pressure of explosion of the former was longer sustained than that of the latter, and the pressures produced for a given volume were equally good; therefore, more power was obtained from a cubic foot in Glasgow than in Oldham. Pure hydrogen, which was very commonly thought to be the best, was shown to be the poorest. An engine which would indicate 10 h.-p. with coal-gas would not indicate more than 3·7 h.-p. with pure hydrogen. The author's results were in complete accord with those of previous experimenters on the question of the existence of a limit; in no case did the heat accounted for by the explosion pressure amount to more than 77 per cent of the total heat present as inflammable gas; in the majority of cases it was little over 50 per cent. In the author's opinion, no single theory previously stated accounted for all the phenomena of these explosion curves. Although all experimenters were agreed upon the fact of the deficiency of pressure, they differed upon the causes producing this result. Three theories had been propounded:—

Theory of Limit by Cooling.

This was Hirn's theory. It supposed that when explosion occurred a point was attained when the cooling effect of the enclosing walls was so great, that heat was abstracted more rapidly than it was evolved, and accordingly the combustion, although continuing, did not proceed with sufficient rapidity to prevent fall of pressure.

Theory of Limit by Dissociation.

This was Bunsen's theory, and was undoubtedly very largely true. The fact that no unlimited temperature could be attained by combustion was so conclusively established, both by science and by practice, that gradual combustion from that cause might be safely taken as occurring at the higher temperatures of gas-engine explosions. There was, however, a difficulty in applying it to all cases. In an experiment with Oldham coal-gas, when the maximum temperature of the explosion was 806° C., the apparent loss of heat was 65 per cent, while in an explosion with a maximum temperature of 1733° C. the apparent loss of heat was only 38 per cent.

With hydrogen mixtures the same thing occurred:—

Max. temp. 900° C., apparent evolution of heat 55 p.c.
,, ,, 1700° C. ,, ,, ,, 54 p.c.

If dissociation entirely explained the limit, then, as water and carbonic acid must be dissociated more at the higher than at the lower temperature, the deficiency should be greater at 1700° C. than at 900°. It was not so. Some other cause than dissociation must therefore be acting to check the increase so powerfully at the lower temperature. The problem was more complex than had been hitherto supposed.

Theory of Limit by the Increasing Specific Heat of the Heated Gases.

According to Messrs. Mallard and Le Chatelier, the specific heat of nitrogen, oxygen, and the compounds formed by combustion, increased greatly at the higher temperatures; dissociation acted only to a trifling extent below 1800° C. The heat of combustion was all evolved at the maximum temperature of the explosion; but as the specific heat changed, calculation from the specific heat at ordinary temperatures was erroneous. The deficiency of pressure was therefore a measure of the increased capacity for heat of the reacting gases. The crucial point of this theory was the supposition that combustion was complete at the maximum temperatures; if it could be shown that combustion was not complete, then the whole theory fell to the ground. The author's experiments seemed to him to prove conclusively that combustion was incomplete; this has been done by a study of the curves of the rates of cooling of various explosions.

Fuller account of the Phenomena during Explosion.

In the author's opinion no single cause explained the limit in all cases of explosion. The actions operating were much more complex than had been generally supposed. To him it seemed that much confusion had arisen through neglecting to distinguish properly between two

distinct and separate phenomena, which occurred during explosion. These phenomena were the inflammation or filling of the explosion vessel with flame, and the completion of the burning which was so originated. The explosion-curves with coal-gas showed some extraordinary features; in many cases an actual check seemed to occur in the rising curve, lasting for some time, followed by an increase of pressure, but at a slower rate than before the check. It was noticeable that the strongest mixtures showed it most distinctly. The hydrogen curves exhibited no such check. It seemed, then, that not only might combustion be incomplete when the vessel was filled entirely with flame; but the pressure at that time might not have attained its maximum, and might continue to increase rapidly after that point.

Why did the pressure again increase after the pause in the explosion curve? The author suggested what he considered a sufficient explanation. In an ordinary fire-grate, a flame communicated to the coal at one point gradually spread till the whole was incandescent. The solid coal might be every part of it burning, and yet a further accession of air would cause it to glow more brightly—that was, to increase in temperature. Explosions had often occurred in flour-mills and in coal-mines from the diffusion, throughout the air, of minute combustible particles of flour and of coal-dust. If present in suitable quantity a flame applied at one part caused an explosion. It by no means followed, however, that complete inflammation coincided with maximum pressure; the pressure might still increase.

In coal-gas explosions the flame had filled the vessel before any check occurred, and then the hydrocarbons decomposed, causing a pause, which gave way to increase when the hydrogen and carbon so liberated combined with the free oxygen. In all chemical combinations dilution caused slowness of action, and dilution during a reaction by the products formed made the last part of the action slower than the first.

Conclusions.

1. Messrs. Mallard and Le Chatelier's theory of increased specific heat of the gases—nitrogen and oxygen—at high temperature was, in the author's opinion, erroneous.

2. Dissociation probably occurred at the higher temperatures to a considerable extent, but it was not the sole cause imposing a limit to increase of pressure.

3. Combustion was very similar to other chemical actions, the first part of the reaction occurring rapidly, and proceeding with increasing difficulty as the combination approached completion.

4. The explosion vessel was entirely filled with flame before the combustion was complete.

5. The limiting causes acted after the flame had spread completely.

6. The limiting causes in weak mixtures were diminution in the rate of burning as the reaction approached completion, and consequent limits by cooling. Combustion caused the heat to be evolved at rates greater than, equal to, and less than, the rate of cooling.

QUANTITATIVE CHEMICAL ANALYSIS BY ELECTROLYSIS.

By THOMAS MOORE, Erdington.

The electrolytic method of separating and estimating metals is now so very generally employed that I venture to think the following details of some of the more important processes by myself will be useful to those chemists who practise this method of analysis.

Iron.—To the distinctly acid solution of the ferric sulphate or chloride add a solution of glacial phosphoric acid (containing 15 per cent. of the glacial acid), until the yellow colour completely disappears (in presence of only small quantities of free acid a white gelatinous precipitate appears, which, however, dissolves in the after process); then add a large excess of ammonic carbonate, and gently warm until a clear solution is obtained. On electrolysing the hot (70° C.) solution by a current equal to 1200 c.c. mixed gases per hour, the iron is rapidly and completely deposited at the rate of about 0·75 grm. per hour: the end of the decomposition is recognised by testing a portion of the solution with ammonic sulphide. Potassic sulphocyanide gives no reaction in presence of phosphoric acid. Aluminium, chromium, and manganese also give a clear solution by the above treatment, but no deposition; the two latter, however, may be precipitated from the remaining solution by sodic sulphide (the ammonic salt having no effect), first, of course, reducing the chromium which has been converted into a chromate by the current.

Cobalt and Nickel, treated as above, give excellent solutions for complete electrolytic deposition when used either hot or cold. If chromium is present the deposition has a remarkably brilliant appearance, which is quite characteristic.

Zinc, submitted to the same treatment, gives a clear solution, from which a current equal to 100 to 300 c.c. mixed gases per hour readily deposits the metal as a shining, coherent coating, which may be washed, dried, &c., without fear of oxidation. If excess of ammonic carbonate is added to a solution prepared by precipitating the solution by sodic phosphate, and dissolving this pre-precipitate in potassic cyanide, a solution is obtained which when electrolysed hot (80° C.) gives an exceedingly rapid and complete deposit. A current equal to 1000 c.c. mixed gases per hour is used. Zinc (also Ni and Co, and to a certain extent Fe) may also be quantitatively separated from its glacial phosphoric acid solution by a current equal to 1300 c.c. mixed gases per hour. Zinc is best deposited on a silver-plated electrode, since it is very difficult to dissolve the whole of it off a platinum one, even by boiling concentrated acids.

Iron, Cobalt, Nickel, Zinc.—When a solution containing the four metals is treated with phosphoric acid and ammonic carbonate, and then electrolysed the whole of them are completely deposited. Cr if present forms a soluble chromate, Mn is partially deposited as oxide on the opposite electrode, Al remains unaltered.

Manganese.—In all cases it is better to estimate this metal as oxide by deposition on the positive electrode, using slightly acid solution of the nitrate or sulphate: it is, however, interesting to note that a very large proportion of the metal may be successfully deposited as such by employing a neutral solution containing a large excess of ammonic sulphocyanide. A powerful current is necessary.

Copper, when met with in the course of analysis as recently precipitated sulphide, should be dissolved in potassic cyanide, and the warm (70° C.) solution, after addition of excess of ammonic carbonate, electrolytically decomposed. The deposition is exceedingly rapid and perfect.

Cadmium.—The electrolytic estimation of this metal is very similar to that of zinc, and may be successfully deposited from any of the solutions given for that metal. A weak current (40 c.c. mixed gases) readily deposits all metal from its glacial phosphoric acid solution, whilst zinc under similar conditions gives no deposit whatever.

Bismuth.—As is well known, the difficulty of obtaining a good deposition of bismuth is considerable, but by carefully attending to the following instructions really good and reliable deposits may be obtained:—Add sufficient tartaric acid to prevent the precipitation of a basic salt; then, after rendering the solution slightly alkaline with ammonia, add a considerable excess of glacial phosphoric acid, so that the solution has a strong acid reaction. The solution so prepared is first decomposed by a weak current (20 to 30 c.c. per hour), but as the decomposition proceeds a much stronger one may be employed (450 c.c. per hour).

The deposit, which at first appears as a loose powdery film, gradually assumes a metallic lustre and becomes exceedingly hard and compact.

Tin is easily deposited, either from its acid or alkaline glacial phosphoric acid solution.

Arsenic.—An attempt to estimate As as AsH_3, by electrolysing its acid solution in presence of a large quantity of zinc sulphate, catching the AsH_3 in U-tubes containing $AgNO_3$, getting rid of excess of silver by HCl, and titrating the As_2O_3 in the filtrate with iodine and starch, gave only approximate results.

ANALYSES OF COMMERCIAL FERTILISERS.*

(Concluded from p. 203.)

The Analysis of Manure Salt.

At the request of some of the members Mr. Gladding read some notes on the analysis of manure salt:—

A sample of manure salt analysed by us about a year ago tested 42·10 per cent of potash. A second chemist making it over 43 per cent, a sample was sent to Dr. Jenkins for reference. He made it about 42·50. I wrote to him that we must agree better than that, and suggested that we repeat the work. The result of this further work was very curious. Though following the instructions adopted at Philadelphia most carefully, and doing the work personally, our results varied all the way from 42 to 43 per cent. We could neither agree with the other nor with ourselves. The only explanation I can give for this remarkable work is that I subsequently found that the manure salt contained a large amount of magnesia which was not precipitated by barium hydrate nor ammonium carbonate, but came down with the platinum precipitate and was only partially washed out by the 90 per cent alcohol. By washing with NH_4Cl solution, however, this sample gave me accurately agreeing duplicates of 42·20 and 42·23 per cent.

Another very curious illustration of the errors liable to occur in the estimation of potash is the following:—

I prepared a solution of platinum by precipitating on zinc, washing with boiling concentrated HNO_3, then dissolving in *aqua regia*, then evaporating to dryness to draw off free HCl. Five c.c. of this solution evaporated to dryness dissolved perfectly in alcohol, but on testing chemically pure KCl with it I obtained 102 to 103 every time. But washing the solution with NH_4Cl solution, the impurity, whatever it was, was washed out, and the results came down to 100 per cent; and further washing with NH_4Cl made no difference.

Nitrogen.

Mr. Chazal made an oral report for the Committee on Nitrogen. In the absence of the other members of his Committee he requested that another Committee be appointed on the Report of the Committee on Nitrogen, and on the method to be used in determining nitrogen during the next season. It was so moved and carried.

Committee: Chazal, Jenkins, and Wiley.

In the course of the discussion of methods of determining nitrogen, Prof. Wiley said, with regard to

The Kjeldahl Method,

Mr. President, it is probably true, as Daffert has suggested, that in the estimation of nitrogen by Kjeldahl's method the process goes on in the following way:—

(1.) The sulphuric acid abstracts water from the organic compounds.

(2.) The sulphurous acid produced by the action of the carbonaceous mass formed by the dehydration of the organic substance has a reducing effect upon the nitrogenous bodies present.

(3.) The decomposition products containing nitrogen which are finally formed are converted into ammonium compounds by the energetic oxidation produced by the permanganate of potassium. It is probable, however, that the use of this latter reagent is not absolutely necessary; but without it the duration of the heating with sulphuric acid and anhydrous phosphoric acid must be continued somewhat longer.

Dr. Jenkins has already called attention to the error which is produced in distilling the alkaline mass with zinc, due to the fact that the liberated hydrogen carried over a portion of the alkali mechanically. Pfeiffer and Lehmann recommend a simple apparatus to prevent this mechanical transportation of the alkali. They interpose in the path of the distillation tube a platinum comb surrounded with fragments of glass, which they claim stops and holds the alkali. It is also possible that if the alkali employed contained a trace of nitrate, the action of nascent hydrogen upon it would result in the formation of ammonium, and thus a total amount of ammonia obtained might be greater than that in the original sample. The method of Wilfarth, as already suggested by Dr. Jenkins, does away with the necessity of the use of zinc. By the addition of mercury the time required for heating with the sulphuric acid in some cases was reduced to thirty minutes. Wilfarth states that only in one case was he troubled by the bumping of the liquid during distillation, and never when potassium hydrate is used instead of sodium.

Methods to be Used during the Next Year.

On motion of Prof. Wiley the Report of the Phosphoric Acid Committee was approved, and the method and recommendations proposed by them were adopted.

Dr. Dabney moved that the next Committee on Phosphoric Acid be instructed to request the chemists to whom they send test-samples to make the determinations of water soluble and citrate insoluble (citrate soluble indirectly) during a particular week to be named by the Committee. Carried.

On motion of Mr. Chazal the Report of the Potash Committee was approved, and their method and recommendations were adopted for the next season.

Prof. F. W. Clark, by request of the members, gave a brief discussion of the atomic weight of platinum. He said, in addition, that he washed the Pt_2 precipitate on an ordinary filter, and washed it through into a Pt capsule, in which it can be dried at any temperature.

The Committee on the Report on Nitrogen submitted the following, which was adopted:—

The Committee appointed to consider the Report of the Committee on Nitrogen beg to report that the returns from the samples sent out by the Committee were so few and meagre, and the discrepancies so large, as to make it inadvisable to recommend any method for the determination of nitrogen for use during the next season, and recommend that the entire Report of the last Committee be referred, without further action, to the next Committee on Nitrogen.

P. E. Chazal, Chairman.
E. H. Jenkins.
H. W. Wiley.

This Report was adopted.

Prof. Wiley, said, in this connection,—

Mr. President, I suggest to the next Committee on Nitrogen that in sending out samples for analysis during the next year they include some of chemically pure compounds in which the percentage of nitrogen is definitely known, and that they suggest to the analysts receiving the samples that they first try their apparatus, reagents, and chemicals on these known samples before beginning with the unknown. Having proved the reliability of their manipulation, they will be better satisfied with their results obtained on bodies of unknown composition. I

* From the *Proceedings* of the Second Annual Meeting of the Association of Official Agricultural Chemists, at Washington, D.C., September 1, 1885. Edited by Charles W. Dabney, Jun., Ph.D., North Carolina Agricultural Experiment Station, Secretary.

suggest also that the same course be followed by the other Committees of the Association.

Dr. Dabney added to this suggestion that the Committee send out for test-analyses selected organic nitrogen compounds of well-determined composition, and which can be obtained in perfect purity (well crystallised) to represent various per cents of nitrogen in its several relations in amido, imido, nitro, nitrose, and cyanogen, &c., compounds.

PROCEEDINGS OF SOCIETIES.

CHEMICAL SOCIETY.

Thursday, April 15th, 1886.

Dr. Hugo Müller, F.R.S., President, in the Chair.

Mr. H. R. G. Bamber was formally admitted a Fellow of the Society.

Certificates were read for the first time in favour of Messrs. Edwin Jennings Ball, Ph.D., 15, Trafalgar Square, Chelsea, S.W.; Parvathi Nath Datta, 5, West Newington Place, Edinburgh; Robert Elliot Dorán, Bray, Co. Wicklow; Richard Dormer, Garstan; William Edward Dawson, Pretoria, Transvaal, South Africa; William Dobinson Halliburton, 135, Gower Street, W.C.; John Tysilis Johnson, Glyn Hof, Conway; William Selby Simpson, 95, Darenth Road, Stamford Hill, N.; Henry H. Walker, 35, St. Tham Road, Fulham, S.W.

The following were elected Fellows of the Society:—

Messrs. E. E. Burnett; Cosmo J. Burton; Carl Bennert; Ph.D.; Arthur W. Clayden; Christopher Hodgson; John W. King; Charles Kilpatrick; Arthur R. Ling; Henry O. Mintz; Frank Morel; Robson Roose; Richard Ll. Whiteley.

Mr. R. J. Friswell exhibited a very large specimen of metatolylene diamine, $C_6H_3Me(NH_2)_2$.

The following papers were read:—

41. "*The Eurhodines, a New Class of Colouring Matters.*" By Otto N. Witt, Ph.D.

By acting with orthoamidoazo-compounds on α-naphthylamine hydrochloride, new dye-stuffs may be obtained, which have received the name of *Eurhodines*. The typical eurhodine, prepared from amidoazotoluene and α-naphthylamine, crystallises in orange needles. Its solution in ether is yellow, and shows a brilliant green fluorescence. Its salts are of a scarlet colour. The formula of eurhodine is $C_{17}H_{13}N_3$. By the action of acids it is transformed into eurhodol, $C_{17}H_{12}N_2O$, whilst ethylic nitrite produces the ethylic ether of eurhodol, $C_{17}H_{11}N_2OC_2H_5$. Eurhodine is recognised as amidonaphthylenetoluquinoxaline. A large number of eurhodines may be obtained synthetically by the action of orthodiketones on triamines which have two of the amido-groups in the ortho-position. The substance $C_{20}H_{13}N_4$ formed by the action of phenanthraquinone on 1 : 2 : 4 triamidobenzene has been examined and found to resemble closely the typical eurhodine. The joint oxidation of orthotoluylenediamine and α- and β-naphthol has been studied. α-Naphthol produces a blue dye belonging to the indophenol group, while β-naphthol gives rise to the formation of a new naphthalenetoluquinoxaline. As only two of these are capable of existence, the new compound must be the β-β-isomeride.

42. "*The Action of Sodium on Ethereal Salts of Phenylacetic Acid.*" Part II. By W. R. Hodgkinson.

In this communication the author principally draws attention to the solid substance produced in small quantity by the action of sodium on ethylic phenacetate (phenylacetate) to which reference was made in the previous paper (*Trans.*, 1880, 480).

The products of the reaction were stated to be ethylic acetate; an oil to which the formula $C_{18}H_{20}O_3$ was provisionally given; phenylacetic acid; and the solid body in question, The reaction was represented as occurring between 6 mols. phenacetate and 2 atoms of sodium; but it is difficult to dissolve so large a proportion of sodium without heating too strongly, and it is better to use 8 mols. phenacetate to 2 atoms of sodium.

On examining larger quantities of the oil to which the formula $C_{18}H_{20}O_2$ was given, the author finds that it is not a uniform substance: it decomposes into substances of high boiling-point—water being given off—even when distilled under reduced pressure. If the crude product be hydrolised by means of alcoholic potash, it yields phenacetic acid and a more stable oil; this oil principally consists of a substance which boils at 320° to 325°, and has the composition of dibenzylketone: such a ketone would result from the hydrolysis of ethylic phenacetophenacetate, $Ph.CH_2.CO.CHPh.COOEt$.

The solid substance produced simultaneously with the oil is represented by the formula $C_{24}H_{18}O_3$. It is not an acid, although it is obtained in solution apparently in the form of a sodium-derivative on heating the crude product of the action of sodium with water; but it is easily precipitated from this solution even by absorption of atmospheric carbon dioxide. It is almost insoluble in water, and has no action on test-paper; the aqueous solution, however, gives a deep-red colouration with ferric chloride. It dissolves in strong solutions of potassic carbonate without carbon dioxide being evolved, and also in dilute alcoholic potash; it slowly dissolves in sulphuric acid, and is re-precipitated by water if the acid be not heated. It reacts with ammonia and with hydroxylamine. It is unaffected by heating with water at 210°. It is oxidised with difficulty, and yields a product which is not an acid. It melts at 175°; the fused substance solidifies to a glassy mass which softens at 100° and then assumes a crystalline state, and melts as before at 175°.

The author is of opinion that this substance results from the occurrence of a reaction similar to that recently observed by Baeyer in the case of ethylic sodiomalonate, and that, in fact, it is a *triphenylphloroglucin*,—

$$(C_6H_5)_3C_6H_3O_3,$$

three molecules of ethylic sodium phenacetate condensing to form triphenyltrisodiophloroglucin, three molecules of alcohol being eliminated.

If sodium act at a temperature of 140° to 150° on an excess of ethylic phenacetate, ethylic phenacetophenylsodacetate is produced.

The author has also examined the action of sodium on the ethylic salts of the toluic acids: the para- and meta-compounds appear to undergo a complex decomposition, but the ortho-compound yields ethylic acetate and a ketone, $C_{14}H_{10}O$.

43. "*The Action of Metals on Acids.*" By Henry E. Armstrong.

Our knowledge of the nature of alloys is at present very limited: it is supposed that some metals are capable of combining, but that others form mere mixtures when fused together, the alloy being, as it were, "a solidified solution of the one metal in the other." This differentiation is based on the study of physical properties of alloys in comparison with those of the constituent metals. In certain cases—but these are very few in number—the actual composition of the compound may be deduced:—thus in the case of the tin-copper alloys abrupt changes in electrical conductivity correspond to compounds of the formula $SnCu_4$ and $SnCu_3$, and the curve of conductivity for the tin-gold alloys also exhibits a striking series of maxima and minima from which the existence of definite compounds may be inferred. It appeared possible that, by dissolving alloys in a liquid capable of acting on both metals and determining the electromotive force between the alloy and a less positive metal, evidence of the existence of definite compounds might be obtained if the alloy

dissolved as a whole. At Dr. Armstrong's suggestion a number of determinations of this kind have been made by Messrs. Holland Crompton and W. E. Sumpner, students of the Central Institution, but the investigation is as yet far from being completed; they have measured the E.M.F. between the alloys and platinum in nitric acid by means of an electrometer. The general result is that the method is inapplicable, since the alloys do not as a rule behave as wholes. The E.M.F. observed in several cases is very nearly that between the less positive metal of the alloy and platinum, the more positive constituent dissolving independently and giving rise to a local circuit: thus in the case of copper-zinc alloys the E.M.F. is very nearly that of copper as long as the alloy contains not much less than about 5 per cent of copper; the tin-zinc and tin-copper alloys also have an E.M.F. near to that of the less positive metal until alloys are reached containing but a small proportion of this constituent. In mercury-zinc alloys the more positive metal determines the electromotive force: this apparently is also true of the lead-tin alloys. Slight changes have been observed which, if confirmed by further experiments, are probably significant: thus in the tin-zinc alloys the E.M.F. gradually rises from that of tin as the amount of this metal in the alloy diminishes: it is conceivable that this may be because the zinc acts as a diluent, and separates the more complex tin molecules into simpler more active molecules. On the other hand, the E.M.F. of copper in bronze is slightly lower than that of pure copper, and that of copper in the copper-zinc alloys rich in zinc is also a little lower than that of pure copper: this may be due to the loss of energy in the formation of the alloy.

Dr. Armstrong then pointed out that although the method described was of little value, owing to the irregularity in the behaviour of alloys towards a solvent capable of attacking both metals, more was to be hoped from the employment of a solvent capable of acting upon only one, recent experiments by Mr. Laurie having shown that the E.M.F. between zinc copper alloys and cuprous iodide in a solution of iodine and zinc iodide is about that of zinc until the alloy has the composition $CuZn_2$, when the E.M.F. suddenly falls to very nearly that of copper. Sodium and potassium exhibit a much lower E.M.F. when alloyed with mercury, according to Hockin and Taylor, and it is probable that the examination of a graduated series of their amalgams will afford indications of the composition of the compounds formed.

The E.M.F. between a given metal and platinum in nitric acid varies with the concentration of the acid. The following results were obtained with copper:—

Acid of rel. den. 1·5	E.M.F.	0·98 volt.
3 vols. 1·5 + 1 vol. 1·42 ..	,,	0·84 ,,
1 vol. 1·5 + 1 vol. 1·42 ..	,,	0·63 ,,
1 vol. 1·42	,,	0·57 ,,
1 vol. 1·42 + 1 vol. water	,,	0·75 ,,
1 vol. 1·42 + 3 vols. ,,	,,	0·81 ,,
1 vol. 1·42 + 7 vols. ,,	,,	0·81 ,,

These results appear to be entirely confirmatory of the conclusions already arrived at by Ackworth and Armstrong (*Trans.*, 1877), who found that the reduction of nitric acid was carried further—as indicated by the amount of nitrous oxide and nitrogen produced—when copper is dissolved in highly diluted nitric acid. The high E.M.F. observed on using the most concentrated acid is probably due to the fact that the initial product of reduction, nitrous acid, remains in solution. If the acid be less concentrated the nitrous acid is more or less broken up—

$$(3HNO_2 = 2NO + HNO_3 + H_2O).$$

The considerable rise in E.M.F. as dilution proceeds not improbably arises from the complex molecules of nitric acid being in part resolved into simpler more active molecules. The results also illustrate the importance of supplementing the chemical method of examining complex cases of change such as are involved in the action of metals on nitric acid by the electrical method. No appreciable action takes place during the time requisite to measure E.M.F., and therefore the solution remains practically unchanged in composition, whereas it is continously changing during the entire course of a chemical experiment.

Referring to the action of metals generally on acids generally, Dr. Armstrong pointed out that it is probably impossible for the chemist to pronounce definitely in favour either of the modern view that the metal directly displaces the hydrogen of the acid, or of the older view that the metal displaces the hydrogen from water—the resulting oxide and the acid then interacting to form a salt: the decision of this question must apparently depend upon the determination of the nature of the phenomena during electrolysis of an acid solution. If the acid alone be the electrolyte, then doubtless the modern view is the correct one; but if both water and acid are electrolysed, and in proportions which vary according to the conditions, then both the old and new view of the nature of the action between a metal and the solution of an acid are correct, and the two kinds of change may go on side by side. The view put forward by Dr. Divers, that silver, copper, and mercury exercise an altogether peculiar action on nitric acid, "decomposing the nitric acid into hydroxyl and nitroxyl, and combining with these radicles to form hydroxide and nitrite, which, by secondary reactions, become water, nitrous acid, and metal nitrate," does not appear to be compatible with the view that the interaction of a metal and an acid is essentially a case of electrolysis, there being no reason to suppose that nitric acid can be electrolysed into hydroxyl and nitroxyl; it is not supported by the observations here described on the E.M.F. of copper in acids of various strengths, which show that more depends on the state of the acid than on the metal; and, lastly, silver is incapable of acting on nitric acid, although it readily enters into interaction with the weaker electrolyte, nitrous acid.

NOTICES OF BOOKS.

Watts' Manual of Chemistry, Theoretical and Practical. (Based on Fownes' Manual.) Vol. II., Chemistry of Carbon Compounds, or Organic Chemistry. Second Edition (Thirteenth Edition of Fownes'). By W. A. TILDEN, D.Sc., F.R.S.. V.P.C.S., Professor of Chemistry in the Mason College, Birmingham. London: J. and A. Churchill.

THIS book is a case of compound authorship. To decide with whom the especial responsibility of its merits or demerits must rest might prove very difficult; but that good features must very largely predominate may be very safely concluded in a manual which has passed through the trying ordeal of thirteen editions, and which has earned the favourable opinions of so many teachers. It has been Prof. Tilden's object, as he informs us in the preface, to avoid any needless increase in the bulk of the work, but he considers that it will nevertheless be found to contain all carbon compounds of either theoretical interest or practical importance. This opinion is, in the main, perfectly justified. If there is any section of the work in which we might suggest any modification it is in the account of the coal-tar colours, which is scarcely on a level with the knowledge of the present day. The alizarin group, however, is described as fully as the limits of space permits.

With reference to picric acid, we may remark that text-books of much larger bulk than the one before us, overlook the fact that the yellow stains produced by nitric acid upon the fingers are due to the superficial formation of picric acid.

The notice of cellulose is on a level with the most

recent researches, save that we find no mention of oxycellulose.

Taking the work as a whole, we can by no means wonder at its success. The production of a text-book of manageable compass, clear in its arrangement, giving so much that is essential, and eschewing what is, for the present at least, of secondary value to the student, has been a task no less useful than difficult.

Report of Experiments on the Growth of Wheat for the Second Period of Twenty Years in succession on the same Land. By Sir J. B. LAWES, Bart., LL.D., F.R.S., and J. H. GILBERT, LL.D., Ph.D., F.R.S. London: W. Clowes and Co., Limited.

WE find here a summary of an important part of the far-famed experiments which have for such a length of time been carried on at Rothamsted. It appears that in this case a soil, which in the ordinary course would have received a dressing of manure every season before another crop has grown, has yielded forty successive crops of wheat averaging 14 bushels per acre. The organic nitrogen which at the outset existed in large amount has been of course much reduced. The most important mineral plant-foods, potash and phosphoric acid, have also greatly diminished in quantity. The residual stock, however, is estimated as being still sufficient to grow wheat for a very considerable time, though the crops will gradually become less plentiful.

From experiments with manures, the authors find that, at least as far as wheat is concerned, mineral manures alone add but slightly to the produce grown upon unmanured land. The amount of nitrogen supplied in manures is very greatly in excess of the quantity recovered in increased crops. After a certain point has been reached each further increase of crop requires a proportionately heavier dressing of manure.

As regards unexhausted manures it appears that potash and phosphoric acid form insoluble compounds remaining in the soil and remain available for future crops. Such is not, however, the case with excess of nitrates or ammoniacal salts, as they are washed out by rain or otherwise lost.

Water-Analysis: a Practical Treatise on the Examination of Potable Water. By J. ALFRED WANKLYN and ERNEST THEOPHRON CHAPMAN. Sixth Edition, by J. ALFRED WANKLYN, M.R.C.S. London: Trübner and Co. 1884.

WE have here the most recent addition of a work which has had a most important and upon the whole a favourable influence upon the analysis of water.

As it will be seen by all who have the opportunity of collating all the successive editions, the treatise has undergone certain modifications. The fifth edition, bearing date 1879, contained, like the one now before us, an account of the so-called "moist combustion process," devised, as we are told, by the author and by his "friend Mr. Cooper." This process the inventors have taken the "very unusual," or, as we believe it might be said, the unprecedented, step of patenting. We have on a former occasion expressed our opinion of this transaction, which further consideration has by no means led us to modify. Until 1893 the process is protected against practical criticism and possibly against general adoption. We may indeed ask what would be the condition of analytical chemistry and of "the chemical profession in this country" if this practice were to become general?

Among the matter not to be found in the earliest editions is an account of the water of the Nile, founded upon samples received in 1874 and 1875. The most remarkable point brought out in these analyses is the great annual fluctuation in the proportion of chlorine.

A very striking feature in this edition, as compared, *e.g.*, with the third, is the appearance of certain polemical matter under the title "History of the Ammonia Process of Water-Analysis; and Controversies on Water-Analysis." Whatever may be the rights or the wrongs of this question we have grave doubts as to the policy of thus continually obtruding it upon the chemical public, so many years after the events. Nothing more rapidly finds its level than an analytical process, unless, indeed, it is patented.

A very important addition to the present edition, as compared with the fifth, is that entitled "Verification." Mr. Wanklyn advises that the analyst should satisfy himself that his solutions are in order and his apparatus sufficiently clean by experimenting with distilled water, with the Kent Company's water, or with water filtered through a "silicated carbon" filter. As a further verification he recommends the preparation and analysis of an artificially prepared water containing a known quantity of nitrogenous organic matter, the results actually obtained being compared with the calculated impurity. This proposal is eminently rational and involves no practical difficulties.

In all other respects this latest edition possesses the same merits which have been recognised in its predecessors.

Milk Analysis: a Practical Treatise on the Examination of Milk and its Derivatives, Cream, Butter, and Cheese. By J. ALFRED WANKLYN, M.R C.S. Second Edition. London: Trübner and Co. 1886.

THIS edition differs very little from the first, which appeared as far back as 1873. The author does not adopt certain modifications of his original process, often regarded as improvements. Among these alterations are the proposals to dry for six hours instead of for three or three and a half hours; the suggestion to mix the milk with sand or to spread it out on blotting-paper; the proposal to resort to the Soxhlet digestion with ether, &c. In this work, and in a letter which he addressed to the CHEMICAL NEWS, vol. liii., p. 70, the author suggests that these "improved" methods may involve partial decomposition of some of the substances present. In view of the extremely complex composition of milk, concerning which the last word has by no means been said, we are inclined to suspect that such may be the case.

A fairly complete notice of the article known as butterine, oleomargarine, &c., and of its determination when in admixture with genuine butter might have been usefully added.

In this book, and in its companion volumes on "Tea, Coffee, and Cocoa Analysis" and on "Bread Analysis," we notice a defect for which not the author but the publishers must be held responsible, viz., the absence of lettering on the back. The volumes are of course too thin to admit of the titles being printed across the backs, but they might be lettered lengthways, as is often done. For want of this simple addition the books are very apt to be lost sight of on the library shelves, or at least not to be found except after much loss of time.

Tea, Coffee, and Cocoa: a Practical Treatise on the Analysis of Tea, Coffee, Cocoa, Chocolate, Mate, (Paraguay Tea), &c. By J. ALFRED WANKLYN, M.R.C.S. London: Trübner and Co.

THIS volume bears the date 1874, and is not stated to be a second edition. The author discusses in succession the determination of the ash in tea, of the aqueous extract, the determination of "free and albumenoid" ammonia in the extract of tea; the estimation of total nitrogen, of theine, and of tannin.

Mr. Wanklyn then proceeds to give a similar account of coffee, cocoa, and chocolate. As regards coffee his attention is more largely taken up with the numerous adulterants which have been more or less in vogue for the last century. The author's opinion that "the

mixing of chicory with coffee is really demanded by public taste," should be qualified by an admission that this taste has been artificially created by dealers for their own ends. Further, if the public prefer chicorised coffee this is no justification of the sale of a mixed article in which the cheaper ingredient largely predominates. In France those consumers who prefer the mixed decoction buy coffee whole and often even unroasted, roast and grind it as wanted, and add such a proportion of chicory as their taste dictates. Of all the trade-falsehoods of the day "coffee as in France" is perhaps the most glaring.

A notice of the kola-nut and of its dietetic value might be fitly added to this work in the event of a second edition.

In the preface we notice a polemical passage which, however justifiable it may have seemed in 1874, will now fail to be understood by many persons who may have forgotten or have never heard of the circumstances referred to.

CHEMICAL NOTICES FROM FOREIGN SOURCES.

NOTE.—All degrees of temperature are Centigrade unless otherwise expressed.

Comptes Rendus Hebdomadaires des Séances, de l' Académie des Sciences. Vol. cii., No. 14, April 5, 1886.

On the Cerium Tungstates and Chlorotungstates.—P. Didier.

New Method of Preserving and Economising Hops Destined for Use in Breweries.—Louis Bouté.

No. 15, April 12, 1886.

Certain Singular Spectroscopic Phenomena.—A. Ricco.—On March 9 of the present year, with a refractor of 0·25 metre aperture and a direct-vision spectroscope each with two systems of 5 prisms, as the author was observing on an exceedingly brilliant protuberance the inversion of the rays D_1 and D_2, he perceived with surprise that the chromospheric ray D_3 which was very bright appeared double, being divided by a very fine black line. This observation was made with the slit of the spectroscope tangential to the margin. On turning the spectroscope round 90° the phenomenon was produced over the entire height of the protuberance. The same thing was seen still more easily in the chromospheric rays C and F. The author repeated these observations on the following days in various conditions of the sky. He has repeated them also with the diffraction spectroscope in the ray C and with spectra of from the first to the fifth order, where the dispersion is almost equal to that of the refraction-spectroscope.

Thermo-Electric Properties of Some Substances.—G. Chaperon.—The author has examined a number of combinations on account of their possible application to thermo-electric generators.

Density and Compressibility of Gases and Vapours.—Auguste Charpentier.—The compressibility of atmospheric air approaches that of nitrogen.

Transformation of Chromium Monochloride into the Sesquichloride. Molecular Conditions of Chromium Oxide.—M. Recoura.—The author has studied the heat of the conversion of anhydrous chromium monochloride into anhydrous chromium sesquichloride, and finds it to be + 39·4 cal. Chromium oxide precipitated from the sesquichloride and that from the oxychloride are not in the same molecular conditions. The former combines with 3 mols. of hydrochloric acid, but the latter with 2 mols. only. The first mentioned oxide can be dissolved and brought to a final state by 9 mols. of soda, whilst the latter requires 3 only. The oxide thus modified, whether derived from the sesquichloride or the oxychloride, combines only with 2 mols. of hydrochloric acid.

On Certain Chlorised Ethers.—L. Godefroy.—The monochlorous vinylethylic ether which the author has discovered has enabled him to prepare six other ethers, which form two distinct series having general characteristic properties almost opposite. The vinethylic ethers are colourless, not fuming on exposure to air, of a sweet penetrating odour, becoming more aromatic as they contain more chlorine. They distil without decomposition. If poured into ammoniacal silver nitrate they do not form a precipitate of silver chloride, but are reduced with formation of a mirror. The ethylic ethers fume in the air; their odour is irritant, but it becomes less so and more aromatic as they contain more chlorine. They are partially decomposed on distillation. If poured into ammoniacal silver nitrate they give an abundant precipitate of silver chloride. On boiling they are reduced, but they do not in general give a silver mirror.

Isomeric Naphthyl-phenyl-carbonyls.—M. Rospendowski.—The α-compound forms crystalline colourless transparent grains of a bright lustre. Its melting-point is 75·5°. The β isomer forms long white silky needles, melting at 82°.

Bulletin de la Société Chimique de Paris.
Vol. xlv., No. 5, March 5, 1886.

Substitution of Pyrites for Sulphur in the Manufacture of Sulphuric Acid and the Improvements effected in their Combustion.—M. Scheurer-Kestner.—The use of pyrites in place of sulphur was originally due to Michel Perret, of Lyon. The same inventor has now succeeded in constructing a furnace which burns smalls better than lump pyrites, and in certain works the lumps are reduced to powder for use. At the Maletra Works, at Petit-Quevilly, the burnt ore now retains only 0·6 to 0·8 per cent of sulphur, and is sold as an iron ore.

Phenyl-mesitylene Carbinol and its Principal Ethers.—E. Louise.—The author describes the preparation of phenyl-mesitylene-carbinol, its ordinary ether, its mixed ethylic ether, the acetic and the benzoic ethers.

Detection of Acid Magenta and of Ordinary Magentas in Wines by the Use of Metallic Oxides.—P. Cazeneuve.—Already noticed.

Conditions of Formation of two Crystalline Nickel Arseniates, and on their Molecular Constitution.—M. Coloriano.—The author obtained a crystalline compound by precipitating 5 c.c. of a solution of nickel nitrate containing 1 grm. of the salt with 5 c.c. of a solution of sodium triarseniate containing 0·5 of the salt, adding 35 c.c. of water, and heating to 235° to 260° for six hours. The crystals when freed from amorphous arseniate contained about 3·5 per cent of water which was not entirely expelled below a red-heat. They form pale green hexagonal prisms, isolated or in groups, very hard and not readily attacked by acids, aqua-regia, and caustic potassa, either cold or hot. They dissolve readily in hydrochloric acid diluted with an equal volume of water at 180° in a sealed tube. A second nickel arseniate formed on heating arsenic acid to 225° to 240° with an excess of nickel carbonate forms green hexagonal plates and contains 7·33 per cent of water.

Russian Chemical Society.—Session March 7/19, 1885.—M. Kleber gave an exposition of the present state of our knowledge on the chemical composition of the heavenly bodies. The various kinds of heavenly bodies do not present an accidental agglomeration of the various elements of which they are composed. These elements possess, on the contrary, certain properties in common determined by their place in the periodic system. All elements of low atomic weights occur in the heavenly bodies with the sole exception of boron. Among the

other elements only the readily fusible metals are there distributed. The meteorites contain neither zinc nor boron, and in them lead is the only representative of the heavier metals. The analogues of iron are widely distributed in nature; the elements of the platinum group, on the contrary, have not been discovered in any of the celestial bodies hitherto examined. The author added a critical examination of the hypothesis of Lockyer on the dissociation of the elements, contending that it is by no means proved by the facts cited on its behalf by the English savant.

M. Reformatsky sent in a paper on the preparation of the polyatomic alcohols and their derivatives by means o hypochlorous acid.

M. Saytzeff communicated a notice of the synthesis of tertiary alcohols, setting out from the acetones.

M. Shalfeef sent in a memoir on the action of ammonia upon hæmine. The crystals of hæmine treated with an alcoholic solution of ammonia are decolourised, but preserve their crystalline form. They lose their power of double refraction. On the other hand, the brown crystals deposited by the ammoniacal solution are more strongly birefringent than the hæmine itself. The ahthor names the brown crystals hæminic acid, and the residue, insoluble in ammonia, heminostromine.

M. Sabaneff sent in a paper on the preparation and polymerisation of monobromised acetylene.

M. Menschoutkine presented some additional remarks on his work on the formation and decomposition of the amides and the anilides.

M. Loubavine described his experiments on the action of methyl iodide on carbylamine.

According to M. Ordinsky in the volumetric determination of phosphoric acid by means of uranium salts the tincture of cochineal can be used as an indicator. In presence of acetic acid the neutral uranium salts produce in the solutions of cochineal a very characteristic deep green colouration.

M. Favorsky has studied the transformations of the acetylenic carbides.

M. Kondakoff spoke of the action of chlorine upon trimethylethylene and announced that he had undertaken the study of the action of dry chlorine upon isopropylacetylene at $-20°$.

M. Solonina sent in a memoir on the action of dilute acids upon allylic alcohol.

M. Kjander submitted remarks on the correction of thermo chemical data with reference to the contraction of solids and liquids.

The third part of the Society's *Journal* contains a memoir by M. Przibytek on allyl dioxide.

Session April 4/16, 1885.—M. Lidoff sent in the results of his analysis of the ammoniacal waters from Siemens's boilers, heated with turf.

M. Lubavine gave an account of experiments on the action of heat upon a mixture of acetylene and hydrocyanic acid. The formation of pyridine in this reaction, as found by Mr. Ramsay, was not confirmed.

M. Krakau communicated his researches on the action of caustic alkalies upon cinchonine in presence of superheated steam. Among the products he isolated a viscous oil, acting upon light, and two inactive bases, quinoleine and lepidine.

M. Goldstein announced that he had undertaken researches on the capillarity of saline solutions.

M. Nikolukine sent in researches on lead tetrachloride obtained by acting upon lead peroxide in the cold with hydrochloric acid, and separating the tetrachloride from the dichloride, simultaneously formed by means of potassium and ammonium chlorides saturated in the cold, in which liquid the tetrachloride is readily soluble.

M. Potilitzine made a remark on the relation between the initial speeds and the formation-heats of salts.

M. Tcheltzoff communicated researches on the formation-heat of lead peroxide.

Session May 9/21, 1885.—M. Lwoff announced that according to experiments begun by Bougaieff, and continued by Wolkoff, secondary butylic alcohol, contrary to the statement of De Luynes, is not decomposed when heated for eight to sixteen hours to 240° to 250° in a sealed tube.

M. Roubtzoff, on passing ammoniacal gas into tubes filled with pulverised succinimide, and cooled down to $-10°$ and 20°, and afterwards sealing these tubes and heating them to 100° to 200°, has succeeded in fixing the ammonia and converting the contents of the tube into succinamide.

Mdlle. Roundinskaia has effected the dissociation of ammonium parabanate and its transformation into oxaluramide.

M. Menschoutkine presented to the Society two memoirs—"Data to serve for the Comparison of Theories of Substitution and of Structure," and "On the Isomerism of Benzol Derivatives."

M. Kanonnikoff has undertaken researches on the azo-compounds with mixed and substituted radicles and their derivatives.

M. Barzillovsky sent in a note on researches on the reaction of azobenzene and of benzoic aldehyd.

M. Alexeeff has studied the reciprocal solubility of secondary butylic alcohol and of water; the curve of solubilities presents two maxima and two minima; at 107° the two liquids become miscible; *b*, the solubility of salicylic and benzoic acids, and of phenol in the solid state; *c*, the phenomena of the solution of metals in a state of fusion; he finds that the vapours of many metals (*e.g.*, zinc and silver, silver and bismuth) dissolve each other mutually; the liquidation of alloys is explained by the decomposition of solutions in consequence of cooling.

M. Sorokine made a remark on the formation of lactic acid by the decomposition of levulose by means of the caustic alkalies and baryta.

M. Przibytek is studying the addition-products of bromine and hydrocyanic acid to allyl dioxide.

MM. Przybytek and Tamintzin have analysed the ash of the pollen of the Scotch fir. It contains 29 86 per cent of phosphoric anhydride.

M. Diaconoff proposed a new method of determining the combustion-heat of solid organic compounds not readily combustible, consisting in burning them along with glycerin and powdered asbestos.

M. Mikhailoff effects the separation of the globulines and the albumenoids of blood serum by saturating the liquid with crystalline ammonium sulphate finely powdered.

M. Goldstein observes that a solution of calcium chloride in passing through a capillary tube becomes less concentrated.

M. Konovaloff described experiments on the influence of the nature of surfaces upon the dissociation of chemical compounds.

The fifth and sixth parts of the *Journal* of the Society contain the following memoirs:—

Action of oxymethylen upon the amines, by M. Kolotoff.

Preparation of hexyl glycerol, by M. Orloff.

On the aromatic carbides contained in the petroleum of the Caucasus, by M. Dorochenko.

Session of September 12/24, 1885.—M. Tcheltzoff described researches on the formation-heats of calcium, strontium, barium, lead, magnesium, zinc, and copper picrates.

M. Konovaloff spoke of actions of contact in phenomena of dissociation.

M. Goloubeff described the composition of the liquid enclosed in Harden's "Fire Extinguisher." It contains scarcely anything but a mixture of sodium and ammonium chlorides.

M. Wilm sent in the results of analyses of platinum ores according to different methods. None of the methods in use give satisfactory results; the metals of the platinum group, as well as their salts, on precipitation from solu-

tions containing other metals, carry down with them a portion of the latter, which cannot be removed by washing. The same phenomenon is produced on the electrolysis of these solutions.

M. Werner communicated researches on the thermic data for some compounds of the aromatic series, and on the neutralisation-heat of mellitic acid.

M. Glinka has determined the crystalline form of calcium hydroxide.

M. Alexeef remarked, touching the endothermicity of carbon disulphide, that on referring the thermic effect of the formation of the sulphide to a red-heat, indispensable for the reaction, a positive effect is obtained.

M. Saytzeff gave a communication on the oxidation of oleic and elaidic acids by potassium permanganate.

MM. Albitzky and Nikolsky described the non-volatile product of the oxidation of the carbide $C_{12}H_{20}$.

M. Oustinoff gave an account of β-dimethyl-acrylic acid.

M. Barataeff described the action of allyl iodide and ethyl iodide upon ethyl oxalate, and gave an account of methoxyd allyl-acetic acid.

M. Dieff discussed the formation of acetic acid formed by the action of silver acetate upon diallyl-carbonyl tetrabromide.

MM. Tchebotareff and A. Saytzeff spoke of the action of ethyl iodide and zinc upon butyrone.

MM. Gortoloff and A. Saytzeff gave an account of the action of methyl iodide and zinc upon butyrone.

MM. Barataeff and Saytzeff spoke of the action of ethyl iodide and zinc upon diethylacetone.

MM. Oustinoff and Saytzeff described the action of propyl iodide and zinc upon butyrone.

M. Schrœder has determined the densities of aqueous and alcoholic solutions of mercuric chloride.

Bulletin de l'Association des Elèves de M. Fremy.
2nd Series, No. 5. January, 1886.

New Apparatus for the Electrolytic Determination of Copper.—A. H. Low.—A paper taken from the *Proceedings of the Colorado Scientific Society*. The apparatus is an ordinary galvano-plastic arrangement, in which a diaphragm of parchment paper is substituted for the porous earthenware cylinder.

Ixometer of L. Barbey.—This illustrated paper describes an instrument for measuring the viscosity of oils and other liquids. The purity of an oil can be determined by comparing its fluidity with that of a known type.

Areothermic Balance of Dr. F. Mohr for rapidly taking the Densities of Liquids and Solids.—This memoir requires the accompanying figure.

Electrolytic Separation of Zinc and Cadmium.—S. Eliasberg.—Already noticed under the *Zeitschrift fur Analytische Chemie.*

Use of Metallic Oxides for Detecting Coal-Tar Colours in Wines.—P. Cazeneuve.—From the *Comptes Rendus*, already noticed.

Alembic-Stove of M. Moitessier.—Figure and description of a gas-stove.

NOTES AND QUERIES.

*** Our Notes and Queries column was opened for the purpose of giving and obtaining information likely to be of use to our readers generally. We cannot undertake to let this column be the means of transmitting merely private information, or such trade notices as should legitimately come in the advertising columns.

Cement.—If a quantity of waste old mortar were mixed with sandy clay (adding some barrels of fresh slaked lime), and spread evenly over a "si o floor," might it not be made available (for "cement") by watering with a solution of silicate of sodium? Any suggestions will oblige.—H. H.

MEETINGS FOR THE WEEK.

Monday, May 3rd.—Medical, 8.30.
—— Society of Chemical Industry, 8. "The Purification of Water," by A. G. Salamon, F.C.S. "The Treatment of Water for Technical Purposes," by Messrs. Macnab and Beckett.
—— Society of Arts, 8. (Cantor Lectures). "Animal Mechanics," by Dr. B. W. Richardson, F.R.S.
Tuesday, 4th.—Institution of Civil Engineers, 8.
—— Pathological, 8.30.
—— Royal Institution, 3. "The Function of Circulation," by Prof. Arthur Gamgee, F.R.S.
—— Society of Arts, 8. "Japanese Art Work," by Ernest Hart.
Wednesday, 5th.—Society of Arts, 8. Adjourned Discussion on Dr. C. Meymott Tidy's Paper on the "Treatment of Sewage."
Thursday, 6th.—Royal, 4.30.
—— Royal Society Club, 6.30.
—— Royal Institution, 3. "The Alkaloids," by Prof. Dewar, F.R.S.
—— Society of Arts, 8. "The Commerce and Industries of New South Wales," by Edward Coombes.
—— Chemical, 8.
Friday, 7th.—Geologists' Association, 8.
—— Royal Institution, 9. "Dissociation," by Frederick Siemens.
—— Society of Arts, 8. "Indian Manufactures from a Practical Point of View," by B. H. Baden Powell.
Saturday, 8th.—Royal Institution, 3. "How to Form a Judgment on Musical Works," by Prof. Ernst Pauer.
—— Society of Arts, 3. "Electricity," by Professor George Forbes.
—— Physical, 3. "On a Modified Form of Wheatstone's Rheostat," by Shelford Bidwell.

TO CARBOLIC ACID AND DISINFECTANT MANUFACTURERS.

The Cartage Committee of the Hammersmith Vestry will be prepared, at its meeting to be held on Tuesday, May 11th, 1886, at 10 o'clock in the forenoon, to receive Tenders for the supply of CARBOLIC ACID at per gallon, and CARBOLIC DISINFECTING POWDER at per ton, and in 1 lb. packets at per gross.

The Acid to be supplied must contain about 90 per cent of Carbolic and Cresylic Acids, and the Powder to contain not less than 15 per cent of Carbolic Acid.

Any further information and forms of tender may be obtained upon application at the Vestry Hall, Broadway, Hammersmith, on and after Monday next, the 3rd of May, 1886.

Tenders, accompanied by samples of Acid and Powder, must be delivered here, not later than 9 30 a.m., on Tuesday, the 11th of May, marked "Tender for Disinfectants."

The Committee does not bind itself to accept the lowest or any tender.

(By order) W. P. COCKBURN, Vestry Clerk.

Vestry Hall, Broadway, Hammersmith,
29th April, 1886.

CRUDE SULPHATE OF ALUMINA.

Vol. LIII. No. 1380.

THE TREATMENT OF SEWAGE.

By F. MAXWELL LYTE, F.I.C., F.C.S.

Of all the methods of sewage precipitation the most effective seems to be that by aluminium hydroxide, and the cheapest and most advantageous mode of its formation is undoubtedly that by means of aluminium sulphate and sodium aluminate. The composition of this latter salt would appear to be not as yet fully determined. Roscoe gives $Na_2Al_2O_4=165$; Wurtz, $Na_6Al_4O_9=392$; and Groves $Na_6Al_2O_6=289$. It is possible that where sodium aluminate is formed by decomposing cryolyte with calcic hydrate, Groves's compound is formed; but otherwise the published analyses of aluminates hardly seem to me to justify the assumption that any aluminates exist of determined composition and of this constitution.

The percentages given for aluminates by Unverdorben, Vauquelin, and others, point to the correctnesss of the formula of Roscoe; but the instructions of Merijot and Debize, in their French translation of Knapp's "Chemical Technology," would rather imply that Wurtz's formula is the right one.

It seems to me probable that really chemically pure aluminates, in which the maximum of base is combined with the alumina, are of Roscoe's composition, but that for practical purposes, on account of the small quantity of silica and other impurities contained in the bauxite from which it is made, it is perhaps preferable to use the proportions indicated by the formula of Wurtz.

When sodium aluminate is mixed with aluminium sulphate the following reaction takes place, adopting, for reasons above mentioned, the formula of Wurtz:—

$$Na_6Al_4O_9+Al_2(SO_4)_3 18H_2O = \\ =3Na_2SO_4+3Al_2(HO)_6+9H_2O.$$

According to this, 6·68 grains of commercial aluminium sulphate containing 13·6 per cent of alumina, and 5·43 grains of crude sodium aluminate containing 27·3 per cent of soda and 33·5 of alumina, will produce as much aluminium hydroxide as 20 grains of aluminium sulphate of same composition with its quantum of lime; and in the former case only 3¼ grains of sodic sulphate (a perfectly innocuous salt) pass into solution, whereas in the latter there is dissolved about 10¼ grains of calcic sulphate per gallon, communicating to the effluent nearly 8 degrees of permanent hardness over and above that it originally possessed.

Suppose, for instance, 1,000,000 gallons of sewage, requiring for purification an addition of (say) 20 grains of commercial sulphate per gallon; this would take 20,000,000 grains = 1 ton 617 lbs., and about (say) 800 lbs. of lime, costing about £5, whereas the same end would be obtained with 954 lbs. of the same sulphate and 776 lbs. of crude aluminate, which, putting the first at £1 10s. and the second at £1 11s., makes in all but £3 1s. as against £5 for the old alum process; and further, in collecting the sludge formed by the old process, rather under ¼ of a ton of quicklime has to be added in order to get it to press, rendering it quite worthless as a manure; whereas with the aluminate process, the sludge, being in large part produced from alumina in alkaline combination, does not require the addition of lime. Experiments which have been made in view of valuing the dry sludge from the aluminate and sulphate process, have gone to show that it possesses a manurial value of 17s. 6d. a ton for nitrogen and phosphoric acid; but this is probably too low, as the sewage operated upon was of but poor quality, being swollen by rain till its volume was fully four times greater than usual.

Adopting it, however, for the moment, at the present price of soda ash, and that of French bauxite (17s. 6d. a ton f.o.b. Marseilles) for the latter, aluminate of soda may be made at good profit so easily that this treatment with aluminate and sulphate costs half, or nearly so, the price of the old process. In saying this allowance is made, on the one hand, for the value of the lime to be added to the sulphate, as well as that required for pressing the sludge in the old method, while, on the other hand, the value of the dried sludge from the aluminate and sulphate process is taken at 16s. a ton, in deduction of the cost by this method. Where, then, precipitation is to be employed, whether in conjunction with irrigation or not, the advantage of this process is evident.

Sewage treated in this way, with the quantities above stated, will be found to give an effluent of great purity, reducing to a minimum, if it does not in all cases obviate, the necessity for subsequent irrigation. Of course less quantities of aluminate and sulphate may be used, but the above are merely adopted as an example, being an equivalent of the 20 grains of sulphate lately used by the A B C Company in some demonstrations they were making with very good results; but whether the aluminium hydroxide formed be intended for use in this or any other process, the above method is by far the best way of forming it. Sodium aluminate is not at present produced on a large scale in England, but its manufacture is easy and advantageous, and doubtless it will not remain long without being made over here.

Besides the above action of the two salts aluminate and sulphate, conjoined in the formation of aluminium hydroxide for the treatment of sewage, there is also the use of aluminate, instead of carbonate of soda or caustic, which presents some advantages in the softening of permanently hard water for industrial purposes. Aluminate of soda, 27 or 28 per cent Na_2O, at £4 13s. per ton, being the equivalent, so far as the Na_2O is concerned, of caustic 60 per cent Na_2O, at £10 a ton; and while it acts just as effectively on the lime salts, producing permanent hardness, reacts far better on the salts of magnesium, to which part of the permanent hardness is often due, producing with them insoluble aluminate of magnesia, provided the carbonic acid be first of all rendered insoluble by an addition of lime-water. The difficulty of treating magnesian hardness is well known and recognised, and this takes place in virtue of the reaction shown by the formula—

$$Na_2Al_4O_9+3MgSO_4 = Mg_3Al_4O_9+3Na_2SO_4.$$

At the present price of soda-ash and bauxite aluminate of soda should be able to be produced for less than the above price, the manufacture of aluminate involving neither so long an operation or so much manipulation as caustic, and leaving no residue.

DO THE FLUORESCENCES OF $Z\alpha$ AND $Z\beta$ BELONG TO DIFFERENT EARTHS?

By M. LECOQ DE BOISBAUDRAN.

The author has expressed the opinion (*Comptes Rendus*, 1885, June, 1440, and September, 59) that the fluorescent bands near $\lambda=573$ and $\lambda=543$ characterise two special earths, which he has provisionally named $Z\alpha$ and $Z\beta$. His recent observations appear to agree with this view. The following are the facts:—

In the spectrum briefly described in *Comptes Rendus*, June, 1885, pp. 1437-38, the following bands belong to $Z\alpha$, or at least present features too analogous for it to be permissible to ascribe them to distinct elements:—

$$Z\alpha \begin{cases} 104\frac{9}{10} & .. \quad .. \quad \lambda=573 \\ 147\frac{1}{2} & .. \quad .. \quad \lambda=476\frac{1}{2}. \end{cases}$$

The other bands preserve among themselves relations of intensity as if belonging to one and the same body, $Z\beta$, the variations observed not being sufficiently decisive to indicate clearly the complexity of $Z\beta$.

$$|Z\beta \begin{cases} 91\frac{1}{2} & .. \; .. \; \lambda = 620\frac{1}{2} \\ 101 & .. \; .. \; \lambda = 585\frac{1}{2} \text{ double} \\ 115\frac{1}{2} & .. \; .. \; \lambda = 543\frac{1}{2} \\ 141\frac{1}{2} & .. \; .. \; \lambda = 487. \end{cases}$$

Relatively to the earth $Z\beta$, the earth $Z\alpha$ is at the first end of the fractionated precipitations by ammonia, and at the last end of the fractionations by potassium sulphate, or strong hydrochloric acid.

The addition of a very slight quantity of ruthenic, platinic, or ferric chlorides to solutions very rich in $Z\alpha$ and $Z\beta$, occasions the extinction or the weakening of all the bands of $Z\beta$, whilst $Z\alpha$ $104{,}^{9}_{0}$ is relatively little affected. We might here, therefore, advance one of the objections presented by Mr. Crookes, and say that $Z\alpha$ and $Z\beta$ are one and the same earth (Yt_2O_3 according to Mr. Crookes), whose different fluorescent bands undergo unequal alterations on the part of the foreign bodies present.

Nevertheless the experiment with ruthenium, platinum, and iron chlorides seems rather to speak in favour of the individuality of $Z\alpha$ and $Z\beta$. The author has indeed already pointed out the propinquity of the bands $Z\alpha$ $104{,}^{9}_{0}$ and $Z\beta$ 101; there is even a decided superposition of these bands. Thus the left margin of $Z\alpha$ $104{,}^{9}_{0}$ (observed in the absence of $Z\beta$ 101) reaches about $101{,}^{9}_{0}$ $\lambda = 584{\cdot}4$), and the right margin of $Z\beta$ 101 is placed nearly at $102{,}^{9}_{0}$ ($\lambda = 579{\cdot}3$). The intersection of the bands is therefore about $1\frac{1}{2}$ division of the micrometer, or $\lambda = 5{\cdot}1$.

It appears to me scarcely probable that the absorption of certain very refrangible rays, inducers of fluorescence, annihilates one of these bands to the exclusion of the other, if both belong to the same earth. Is it not more conceivable that if the rays exciting the fluorescences $Z\alpha$ and $Z\beta$ are of different refrangibilities, those which produce $Z\alpha$ may still act, whilst those corresponding to $Z\beta$ are intercepted?

The solutions of ruthenic, platinic, and ferric chloride absorb, in fact, all the radiations from the ultra-violet to a point which lies nearer the red the more concentrated is the liquid. This limit is not always very abrupt, but it is represented by a zone of rapidly decreasing absorption. But the solutions of the earths in which $Z\alpha$ predominates over $Z\beta$ extinguish the very refrangible rays only by absorption-bands, between which the light passes almost freely: these bands are especially those of holmium (?), erbium, and sometimes samarium and didymium. It was therefore interesting to know the effect of an addition of pure erbia or samaria to solutions giving fine $Z\beta$ spectra.

An earth containing a moderate but decided quantity of holmia, and a smaller proportion of erbia and didymia, was dissolved in hydrochloric acid in excess. By the reduced spark there was produced a fine spectrum of $Z\beta$ and a weaker one of $Z\alpha$. A considerable quantity of pure erbia was then introduced into the liquid, and it was found that the intensity of the fluorescences $Z\alpha$ and $Z\beta$ had not been very notably diminished.

The same experiment was then repeated, substituting for erbia pure oxide of didymium. Here the band $Z\beta$ 101 and a good part of the band $Z\alpha$ $104{,}^{9}_{0}$ were extinguished, by reason of the absorption of this part of the spectrum by didymium. The other bands $Z\beta$ remained very well marked, though rather more reduced than by erbia. The band $91\frac{1}{2}$ was relatively a little more attenuated than $115\frac{1}{2}$ and $141\frac{1}{2}$.

Lastly, the addition of a rather large quantity of pure samaria did not occasion any perceptible decrease in the brightness of the bands $Z\alpha$ and $Z\beta$. The experiment could not be made with holmia, as it has not yet been obtained in a state of purity.

According to these observations the presence of bodies giving discontinuous absorption-spectra along with the earths showing $Z\alpha$ more intense than $Z\beta$, does not seem sufficient to explain the relative feebleness of $Z\beta$ on the hypothesis that both these fluorescences are due to a single body.

Although the experiment could not be made with holmia it remains very probable that the absorption-bands of this earth, like those of erbiia, didymia, and samaria, would act but slightly upon the fluorescences $Z\alpha$ and $Z\beta$. The author, moreover, possesses a terbia containing slight traces of holmium and samarium, without erbium or didymium, the hydrochloric solution of which gives a splendid spectrum of $Z\beta$, with $Z\alpha$ still faintly visible, though incomparably weaker than $Z\beta$. If $Z\alpha$ and $Z\beta$ belong to one and the same earth, by what cause is the fluorescence $Z\alpha$ diminished to this point?

But if the exciting rays of $Z\alpha$ and $Z\beta$ are supposed identical, it may be that one of these fluorescences is produced to the almost complete exclusion of the other,—*e.g.*, in the case where the two fluorescences penetrate to different depths in the liquid. This interpretation is supported by the following experiment:—

If, at the surface of a solution rich in $Z\alpha$ and $Z\beta$ (containing no didymium, and not presenting an absorption-band near 105), we cause the reversed spark to strike about the middle of the liquid (at some millimetres from the side of the tube), we observe an increase in the lustre of the bands $Z\beta$, due doubtless to the fluorescent sheet being seen in section; but the band $Z\alpha$ $104{,}^{9}_{0}$ is extinct or much diminished. On bringing the spark near the side, against the liquid meniscus, $Z\alpha$ is restored to its full strength. This effect seems due to the fluorescence; $Z\alpha$ is produced at a very slight depth in the liquid, whose surface, being distorted by the contact of the electric jet, prevents the light from arriving at the slit of the spectroscope. When by means of the play of a mirror we throw upon the slit not the light emitted horizontally, but that which follows a strongly descending direction, the spectrum of $Z\alpha$ reappears.

The slight depth of the fluorescence $Z\alpha$ may lastly contribute to explain how this fluorescence is moderately influenced by ruthenium, platinum, and iron chlorides, the quantity of these bodies traversed by the exciting rays being very small.

The products which give the most brilliant $Z\alpha$ and $Z\beta$ are those which contain the least yttria or which contain none at all. The author is therefore convinced that the fluorescent spectrum at first attributed to yttria is not due to this earth, and is composed solely of the bands of $Z\alpha$, $Z\beta$, and samarium. He adds that his learned friend Mr. Crookes continues not to accept this opinion.

It results, therefore, from the author's researches that neither holmia nor $Z\alpha$ can be the cause of the orange colouration of the terbias. He does not venture to allege that the earths Ho and $Z\alpha$ are absolutely colourless, not having obtained them pure, but they concentrate themselves in very pale oxides obtained from the fractionation of the terbias, so that their colouration must be very slight.—*Comptes Rendus*, vol. cii., p. 899.

ON THE VANADATES AND IODYRITE FROM LAKE VALLEY, SIERRA CO., NEW MEXICO.*

By F. A. GENTH and GERHARD VOM RATH.

At a meeting of the American Institute of Mining Engineers, held at Washington, D.C., in 1882, the late Prof. Benj. Silliman read a paper "On the Mineral Regions of Southern New Mexico,"† in which he gave the first fuller information about the extraordinary occurrence

* Read before the American Philosophical Society, April 17th, 1885.

† *Engineering and Mining Journal*, New York, October 14 and 21, 1882, pp. 199 and 206; 212, 213, and 214.

of rich silver ores and the accompanying minerals in the mines of the so-called Sierra Group, comprising the Sierra Grande, Sierra Bella, and Sierra Apache.

The geological position had been determined in 1881 by Prof. E. D. Cope, when he showed that the strata in which the ores occur belong to the lower coal-measures.

The ores form a bed more or less interrupted, or rather a series of huge lenticular beds or pockets between the limestone strata, which show a dip of about 30° towards the S.E. This dip flattens to one only of about 15° at a depth of 180 feet. The ore bed is frequently divided by intercalations of limestone strata.

The foot wall consists of a hard, more or less siliceous, blue limestone, with very few fossils, into which the ores frequently penetrate, as if by alteration of the bed rock. The hanging wall is formed by a pale slaty limestone without siliceous inclosures, rich in fossils, but without any ores. The separation between the hanging wall and the ore bed is perfect.

The main body of the ores is formed by oxides of iron and manganese; hæmatite, limonite, pyrolusite, manganite, psilomelane, and wad, intermixed with variable quantities of cerargyrite and embolite, together with small quantities of native silver and highly argentiferous cerussite and galenite. At many places the upper portion of the ore bed consists of flint and siliceous minerals which cover the argentiferous iron ores, and which are sometimes rich in embolite; pale yellow crystals of vanadinite in druses of quartz are sometimes met with.

These facts, mostly taken from Prof. Silliman's paper, give a brief account of the geological position and the accompanying minerals which he had observed.

A few months ago a highly interesting find was made at the Sierra Grande, which furnished some beautiful specimens of very rare species, of which we received a sufficient supply for investigation from Mr. N. H. Muhlenberg, in Lake Valley, and his representative in Reading, Pa., Mr. Theodore A. Kendall, to whom we are greatly indebted for their liberality; also to Mr. Robt. C. Canby, at Pueblo, Coll., who has kindly furnished the writer with the vanadinite from the Sierra Bella.

In the following investigation the crystallographic measurements and figures are by Gerhard vom Rath, and the analyses, &c., by F. A. Genth.

It may be well to give a general outline of the methods employed for the analyses of the vanadates described in this paper.

After dissolving in very dilute nitric acid, the insoluble residue was filtered off, then treated again two or three times with dilute nitric acid in order to bring all the vanadates into solution. This was especially necessary in the case of the dark descloizites; but, notwithstanding this, some of the constituents of this mineral remained undissolved, and appreciable quantities of lead, copper, and zinc were retained, probably by the manganese dioxide, which was present in considerable quantities. These bases were determined, and their quantity added to the main portion.

In the filtrate the chlorine was precipitated by a few drops of silver nitrate, the excess of silver removed by just enough hydrogen chloride, and the filtrate from the silver chloride evaporated nearly to dryness. A large excess of strong hydrogen sulphide water was then added, and the beaker put at a warm place for two days. Lead, copper, and arsenic were precipitated as sulphides, but also, invariably, more or less zinc,* although the solution was still strongly acid. After two days' standing, the solution had yet a strong odour of hydrogen sulphide. It was filtered off, and the arsenious sulphide separated from the sulphides of lead, copper, and zinc, by digestion with sodium hydrate, the filtrate precipitated with hydrogen chloride; the arsenious sulphide, thus obtained, oxidised with strong nitric acid into arsenic acid, which was weighed as pyro-arseniate of magnesium. The precipitate, containing lead, copper, and part of the zinc as sulphides, was oxidised with strong nitric acid; sulphuric acid was then added, and evaporated until the nitric acid was completely expelled. In the filtrate from the lead sulphate the copper was precipitated as sulphide and weighed as oxide, and the zinc converted into sulphide, after neutralisation with ammonia, and added to the main portion.

The filtrate from the first hydrogen sulphide precipitate was evaporated and the tetraoxide of vanadium reconverted into vanadic acid by the nitric acid present, whereupon the solution was boiled with sodium carbonate to separate the zinc, manganese, and iron from the *greater* part of the vanadic and phosphoric acids. As this separation is not complete, the precipitate was fused with sodium carbonate and lixiviated with water, after having reduced the manganic acid by a few drops of alcohol. Iron was separated from zinc and manganese by sodium acetate, the zinc precipitated by hydrogen sulphide from the cold filtrate, after acidulating strongly with acetic acid, and finally the manganese by sodium carbonate. In the united solutions, containing vanadic and phosphoric acids, the sodium carbonate was nearly neutralised with acetic acid, and the two acids precipitated either by mercurous nitrate or lead acetate. In the first case the mercury was driven off at the lowest possible temperature, then a little nitric acid was added, the liquid evaporated to dryness, after which the residue, containing pentoxide of vanadium and metaphosphoric acid, was ignited; in the second place, the lead salt was mixed with a little nitric acid, the lead removed as sulphide, the filtrate evaporated, and the residue ignited.

It now remained to separate the phosphoric acid from the vanadic pentoxide. They were dissolved in boiling hydrogen chloride, completely reduced by sulphurous acid, and, after having added a little tartaric acid and a large excess of ammonia, precipitated with magnesia solution. On account of the minute quantity of phosphoric acid, the liquid was allowed to stand a long time in order to secure a complete precipitation, but, in doing this, a small quantity of the reduced vanadic acid was re-oxidised and contaminated the phosphate with a minute quantity of magnesium-ammonium vanadate. It was necessary, therefore, to re-dissolve in hydrogen chloride, and after addition of a little sulphurous and tartaric acids to re-precipitate by ammonia, when a perfectly white pyrophosphate of magnesium was obtained.

Vanadinite.

Prof. Silliman was the first to observe vanadinite in pale yellow hexagonal crystals at the Lake Valley Mines.

a. At the Sierra Bella it is found on wad in thin coatings, consisting of minute crystals of a brownish yellow colour, which, under the microscope, show bright hexagonal prisms with the basal plane and the pyramid slightly indicated; powder yellow. Analysis *a*.

b. At the Sierra Grande several varieties are found.

1. Beautiful crystals, the largest not over 5 m.m. long and 2·5 to 3 m.m. thick; hexagonal prisms, terminated by the basal plane and the pyramid. The angle between the prism and pyramid was found by measurement to be nearly 130°. The planes are often rough, as if corroded by a solvent, and the crystals frequently show cavities; some appear as skeleton-like residues. Smaller crystals of about 1·5 to 2 m.m. in length are perfectly developed, and show smooth brilliant faces. The colour is orange-yellow, varying from wax-yellow on one side to a deep orange-red, the terminations being generally of the darkest colour; cloudy. Powder pale orange-yellow. Lustre greasy, inclining to vitreous. Associated with pyrolusite and implanted in calcite. Minute very brilliant columbine-red or cherry-red crystals of descloisite are implanted in or crystallised upon the vanadinite and calcite, and may have been formed from constituents of decomposed or dissolved vanadinite. Analysis *b* 1.

* In the analysis of descloisite, *a* 2, the zinc was lost, because the filtrate from the lead sulphate, which contained a portion of it, was accidentally thrown away.

2. Other varieties of vanadinite are associated with the black or dark brown descloizite. They all show the hexagonal prism and the basal plane, and most of the crystals the pyramid also; a more acute pyramid, and a prism and pyramid of the second order are rarely indicated. The planes are generally smooth and brilliant, but there are some, in which the basal plane is rough, as if corroded, but surrounded by a smooth and brilliant margin. The crystals vary in size from 1·5 to 3 m.m. in length, and 0·5 to 2 m.m. in thickness. Their colour is from orange-yellow to brownish orange.

They are mostly of a more recent origin than the brown descloizite which they accompany; it appears, however, that the latter was still growing when this vanadinite and iodyrite were formed, since the large crystals of descloizite are frequently pitted by their impressions; the vanadinite and iodyrite seem to have crystallised simultaneously, but there are smaller crystals of descloizite, of a red colour, of a more recent origin: they are attached to iodyrite, vanadinite, and calcite.

Analyses:—

a. As not enough of the pure mineral from the Sierra Bella could be obtained, an indefinite quantity of the incrustations upon wad was purified as much as possible by washing off the lighter particles, and analysed. It gave—0·0153 grm. Ag = 0·0050 grm. Cl, 0·2261 grm. $PbSO_4$, 0·0007 grm. $Mg_2As_2O_7$, 0·0021 grm. $Mg_2P_2O_7$, and 0·0364 grm. V_2O_5.

b 1. One grm. gave—0·0757 grm. Ag = 0·0249 grm. Cl, 1·0647 grm. $PbSO_4$, and 0·1814 grm. $(VP)_2O_5$. 1·5665 grm., after deducting 0·0008 grm. quartz, or 1·5657 grm. pure vanadinite, gave—1·6669 grm. $PbSO_4$, 0·0282 grm. $Mg_2As_2O_7$, 0·0095 grm. $Mg_2P_2O_7$, and 0·2779 grm. V_2O_5. These quantities give the following percentage:—

	a. Sierra Bella.		*b*1. Sierra Grande.	
Sp. gr. =	—	Atomic ratio.	6·862	Atomic ratio.
Cl	2·39—0·067	= 1	2·49—[2·49]—0·070	= 1
P_2O_5	0·57—0·004		— 0·39—0·003	
V_2O_5	17·37—0·095	= 0·100 = 1·49	18·14 —17·74—0·097	= 0·106 = 1·5
As_2O_5	0·24—0·001		Not det. — 1·33—0·006	
PbO	79·43—0·356	= 5·31	78·36—78·31—0·351	= 5
ZnO	—		trace	
			Less O	100·26
			Equiv. to Cl	0·55
				99·71

b 1. One grm. gave—[illegible] grm. Ag = 0·0249 grm. Cl, 1·0647 grm. $PbSO_4$, and 0·1814 grm. $(VP)_2O_5$. 1·5665 grm., after deducting 0·0008 grm. quartz, or 1·5657 grm. pure vanadinite, gave—1·6669 grm. $PbSO_4$, 0·0282 grm. $Mg_2As_2O_7$, 0·0095 grm. $Mg_2P_2O_7$, and 0·2779 grm. V_2O_5. These quantities give the following percentage:—

The analysis *b* 1 corresponds exactly to the formula $Pb_5Cl[(VAsP)O_4]_3$, in which a small portion of the vanadium is replaced by arsenic and phosphorus, while analysis shows a slight excess of lead, which is probably present as cerussite.

Endlichite, or Vanadium-Mimetite, a New Species.

In the collection of Mr. Clarence S. Bement was a specimen, labelled Vanadinite, which showed such a peculiar appearance that its examination was desirable, for which purpose he has kindly loaned the same.

There are apparently three kinds of crystals present; some of an orange-yellow and orange-red colour, probably vanadinite; the largest a little over 1 m.m. in size: they are hexagonal prisms with pyramid, and, slightly developed, a second more acute pyramid; both the prismatic and the pyramidal planes are strongly striated through oscillation of the pyramidal planes with the prismatic; then there are one or two bright yellow, very minute crystals, which are imperfect, and appear as if made up of several individuals: the planes are the same as those of the orange crystals. The third mineral is developed in the form of very bright straw-yellow crystals, showing the strong striation of the prismatic planes and the two pyramids. On the largest crystals, not over 1 m.m. in length, the basal plane is visible; on the small ones it is quite obliterated. A few of the crystals were hollow.

An imperfect qualitative analysis gave no satisfactory results, on account of the exceedingly minute quantity at disposal. Fortunately Mr. Muhlenberg succeeded in securing for examination another small specimen which showed some peculiarities, but was evidently the same as Mr. Bement's specimen. Implanted in drusy quartz coloured by ferric and manganic oxides, the crystals are yellowish white or pale straw-yellow, the largest 3 m.m. long and from 0·5 to 1·5 m.m. thick; the forms are those given above. Some of the crystals show only a hollow prism, either empty or filled with a crystalline powder which now and then assumes hexagonal forms. As the specimen contained only a very minute quantity which could not be picked out, an analysis was made from all the fragments of quartz which showed some of this mineral. On dissolving in dilute nitric acid a slight evolution of carbonic dioxide was observed.

0·9518 grm. gave—0·7276 grm. insoluble quartz, &c., 0·0094 grm. Fe_2O_3, 0·0029 grm. CaO, 0·0127 grm. Ag = 0·00417 grm. Cl, 0·0277 grm. $Mg_2As_2O_7$, 0·0152 grm. V_2O_5, and an unweighable trace of $Mg_2P_2O_7$. This gives—

Quartz, &c.	76·44 per cent.
Fe_2O_3	0·99
CaO	0·30
Cl	0·44
As_2O_5	2·16
P_2O_5	trace
V_2O_5	1·60
PbO	15·94
CO_2, H_2O, &c.	2·13 by difference.
	100·00

Deducting the admixtures the pure mineral contains—

		Atomic ratio.
Cl	2·18 = 0·061	= 1
As_2O_5	10·73 = 0·047	= 0·090 = 1·48
V_2O_5	7·94 = 0·043	
PbO	79·15 = 0·355	= 5·82
	100·00	

The small excess of lead is evidently owing to an admixture of cerussite, and the mineral is a combination of 1 molecule of mimetite with 1 molecule of vanadinite =

$$= Pb_5Cl[AsO_4]_3 + Pb_5Cl[VO_4]_3,$$

corresponding to which is the following:—

Cl	2·44
Pb	7·11
As_2O_5	11·86
V_2O_5	9·60
PbO	68·99
	100·00

The name has been suggested by Mr. N. H. Muhlenberg in honour of Dr. F. M. Endlich, Superintendent of the Sierra Mines at Lake Valley, N.M.

Since the above has been written Mr. Muhlenberg sent a new supply of endlichite which was different in appearance from that previously seen. It consisted of groups of crystals of a columnar structure, some radiating from a centre, and also forming sheaf-like aggregations. In many of them the hexagonal form could be distinctly seen, especially towards the diverging ends, which show the basal plane and pyramid very distinctly. They are all strongly striated. The individual crystals are white and yellowish white or straw-yellow, towards their terminations often changing to yellow, and in a few groups to a deep orange-red. The largest groups were 10 m.m. in length.

The whitest gave a sp. gr. of 6·864, and contained—

		Atomic ratio.	
Cl	2·45	= 0·069	
PbO	73·48	= 0·330	= 0·336
CaO	0·34	= 0·006	
As_2O_5	13·52	= 0·087	
V_2O_5	10·98	= 0·084	
P_2O_5	trace		
	100·77		

From this the ratio of the constituents appears to be about the same as found before, and that arsenic and vanadium are present in the proportion of 1 : 1.

The change of colour of these groups of crystals, however, appears to indicate that the vanadiferous mimetite or endlichite may gradually change into vanadinite.

Probably the same mineral has already been observed by Prof. Silliman at the Torrence Mine, Socorro, N.M., where it occurs in small yellow hexagonal prisms which were mistaken for vanadinite, but were mimetite containing vanadium.

ON THE DETERMINATION OF ARSENIC.*

By LeROY W. McCAY.

Arsenic and its compounds have until lately proved very unsatisfactory things for the chemist to determine. There are indeed few common elements the quantitative estimation of which has, up to within the last few years, presented such numerous, persistent, and extraordinary difficulties as the one forming the subject of this paper. As a matter of fact there is, at the present day, no gravimetric method for estimating arsenic which is not without fault. The one most commonly used, that of Levol, is open to at least two serious objections. In the first place the ammonium magnesium arseniate is perceptibly soluble in ammonia water, and in the second place the danger of occasioning a loss of arsenic by the reducing action of the ammonia upon igniting the salt is a fact too well known to need mention. Chemists, it will be remembered, have endeavoured to avoid the error arising in the first instance by the addition of alcohol to the solution to be precipitated, but even in ammoniacal alcohol the double arseniate is sensibly soluble; consequently, although considerably reduced, the error cannot be said to be entirely eliminated. Attempts have also been made, and that too with a considerable amount of success, to avoid the error arising in the second instance by removing the salt particles adhering to the filter-paper with dilute nitric acid, moistening the precipitate with the same reagent, and igniting—at first gently, then strongly. Much skill and care, however, is requisite in the process of igniting, it being no uncommon occurrence, when the heat is too suddenly applied, to drive off a portion of the ammonia at such a rate as to occasion considerable reduction, even in such a strong oxidising atmosphere as nitrous oxide.†

Not long since Bunsen* published an article upon the separation of arsenic and antimony, and upon the determination of each as sulphide. The separation of the two elements is quick, easy, and accurate. As regards the estimation of the arsenic, however, it is, as Fresenius has already intimated, undoubtedly necessary, in order to ensure correct results, to follow Bunsen's details to the letter; for although the sulphide obtained by precipitating the arsenic from a solution thoroughly treated with chlorine has, after having undergone a detailed course of washing, exactly the composition of arsenic pentasulphide, and is in fact regarded by Bunsen as being such, it must not be forgotten that no less an authority than Rose† declares the precipitate occasioned by sulphuretted hydrogen in solutions of arsenic acid to be not pure arsenic pentasulphide, As_2S_5, but a mixture of the trisulphide, As_2S_3, and sulphur. If Rose's statement is true, then the chances are that a slight departure from the directions as given by Bunsen might occasion incorrect results in the determination of the element. Besides the objection to be found in the uncertainty as to the actual character of the sulphide obtained by neglecting to follow Bunsen's details absolutely, another and serious one can be urged against the necessity of being compelled to weigh the precipitate on a tared filter-paper after having thoroughly dried at 110° C. I willingly grant that the Bunsen method furnishes perfectly correct results, and that it is a wonderful improvement upon the old method of Levol; still it is a long, tedious, and unpleasant operation. The arsenic is precipitated very slowly from the solution of arsenic acid, and unless the precipitate is filtered off at just the right point some arsenic is sure to remain in solution. The precipitation, in fact, requires much attention, patience, and practice, and in consequence thereof it is with much pleasure and satisfaction that we welcome the beautiful proposal of Carl Holthof.‡

Mohr's method for estimating arsenic is one of the most simple and exact in the field of analytical chemistry. It presupposes, however, the existence of the arsenic in the state of arsenious acid, a condition which is rarely fulfilled, inasmuch as in the regular course of analysis arsenic is almost invariably obtained as arsenic trisulphide or arsenic acid. The method, it will be remembered, depends upon the fact that in a weakly alkaline solution arsenic in the state of arsenious acid is oxidised by iodine to arsenic acid, in accordance with the equation—

$$H_3AsO_3 + 2I + H_2O = H_3AsO_4 + 2HI.$$

The difficulty of obtaining the arsenic in the minimum state of oxidation has caused the method of Mohr to fall into neglect, and consequently escape that attention which is due to it.

Many years ago Holthof obtained very satisfactory results by carefully oxidising small quantities of sulphide of arsenic with nitric acid in a porcelain dish, evaporating to dryness with a few drops of sulphuric acid, and boiling down in a large beaker to one-third the original volume, after having first added one-third of a litre of sulphurous acid solution, then re-filling to the mark with sulphurous acid solution, and again evaporating to one-third the original volume, neutralising, after cooling, with sodium carbonate, adding a constant quantity of mono-sodium carbonate, a little starch solution, and titrating with a standard solution of iodine. Holthof evidently did not at that time publish anything relating to this method of determining arsenic, for in speaking of it in the first part of his recent paper he makes no reference to any work or

* *American Chemical Journal*, vol. vii., No. 6.

† Bemmer, who proposes the igniting of the precipitate in an atmosphere of nitrous oxide, directs that the salt be brought into a small thin porcelain crucible; that this crucible be placed in a larger one of platinum, and that the heat be then applied, very gently at first, then gradually stronger, until the full capacity of the burner is reached.

‡ Holthof, *Zeitschr. f. Anal. Chem.*, xxiii., 378.

periodical. A little over a year ago, at the instigation and in the laboratory of Fresenius in Wiesbaden, he undertook a thorough study of the process, it being his chief object to discover whether the mode of procedure was applicable in the case of large quantities of arsenic, and also practicable in determining the arsenic in the strong hydrochloric acid solution which is obtained when working according to the Bunsen separation method. It will be at once evident that the success of the method depends upon the complete reduction of the arsenic from the arsenic to the arsenious state of oxidation. Holthof starts out with the assumption* that when a sufficient quantity of sulphurous acid is used, and the solution is heated for a sufficient length of time, the reduction is complete, and in the end he proves that this is the case.

In brief Holthof's method is as follows:—1. The solution, containing about 0·10 to 0·20 grm. arsenious oxide, As_2O_3, as arsenic oxide, As_2O_5, is brought to 50 c.c. and diluted in a flask with 100 to 150 c.c. sulphurous acid and 150 to 200 c.c. water. The flask with its contents is then heated for four hours, and next boiled down over a free flame to one-half the original volume. A little clear starch solution is now run in, 40 c.c. of a solution of hydrosodium carbonate saturated in the cold added, the whole diluted to about one-third of a litre, and titrated to a light sky-blue, with a standard solution of iodine containing approximately 10·0 grms. iodine to the litre. The test analyses, although not numerous, are very satisfactory.

2. Holthof did not experiment upon sulphide of arsenic, at all events not in the case before us; but his thorough study of the oxidising action of chlorine upon the arsenious acid, and his examination of the question relating to the volatility of arsenic trichloride when a solution of arsenic acid is evaporated to dryness with excess of hydrochloric acid, justify us in presuming that, according to him, the following would be the method of procedure in the case of sulphide of arsenic† :—The sulphide of arsenic is brought into a little porcelain dish provided with a watch-glass cover, and treated either with fuming nitric acid or potassium chlorate and hydrochloric acid until solution is complete. The liquid is then evaporated, a few drops of sulphuric acid added, diluted, reduced as already described, boiled down to one-half the original volume, cooled, evaporated to about 300 c.c., and titrated to a light blue. The test analyses resulting from evaporating arsenic pentoxide, As_2O_5, solutions in the presence of excess of chlorine and hydrochloric acid are good, and prove conclusively that when arsenic acid, chlorine, and hydrochloric acid are evaporated upon the water-bath no arsenic is volatilised as trichloride. The two sets of experiments then prove:—

1st. That the reduction with sulphurous acid is complete. 2nd. That upon evaporating arsenic pentoxide, As_2O_5, in the presence of hydrochloric acid, no arsenic escapes as trichloride.

Holthof concludes from the above that not only is the method suitable for technical needs, but also that its exactness renders it worthy of being used for scientific purposes.

For some time past I have been engaged in making a thorough examination of the method of Holthof, and I have reached the conclusion that it is the most perfect one at present known. Further, by taking advantage of a device of my own, the time requisite for making a determination is reduced to a minimum. At the outset I went over Holthof's work for the purpose of determining whether the reduction, when made in strict accordance with his directions, is so complete as to render it impossible to detect, by qualitative measure, any arsenic acid in the liquid after boiling down to one-half the original volume and then carefully evaporating to about 50 c.c.

In order to obtain a solution suitable for qualitative as well as quantitative experiments, I dissolved 28·90 grms. H_2KAsO_4 in about 250 c.c. water, and diluted to 2 litres. Theoretically every 10 c.c. of this solution should contain 0·0602 grm. As = 0·0794 grm. As_2O_3 = 0·0923 grm. As_2O_5. However, being ignorant as to the exact degree of purity of the salt, the solution was carefully analysed—1st, by the method of Levol; 2nd, by the method of Reich.

1st. Ten c.c. were put into a small beaker, rendered strongly acid with hydrochloric acid, then strongly alkaline with ammonia, cooled, and finally precipitated with magnesia mixture, care being taken to add this reagent slowly, drop by drop, and with constant stirring. After standing twelve hours the ammonium magnesium arseniate was filtered off, washed with ammoniacal water, dried, moistened with nitric acid, and ignited, all details relating to the extraction of the particles of the salt from the filter-paper with dilute nitric acid being strictly observed. The 10 c.c. gave 0·1215 grm. $Mg_2As_2O_7$ = 0·0591 grm. As = 0·0780 grm. As_2O_3 = 0·0906 grm. As_2O_5. These figures, it will be observed, are somewhat lower than those required by theory.

2nd. *Three Estimations.*—*a*. One volumetrically; *b*. Two gravimetrically.

a. Ten c.c. were put into a small beaker, about 50 c.c. water added, and enough ammonia to produce a decided alkaline reaction dropped in. The solution was then heated to boiling, and a quantity of silver nitrate sufficient to ensure complete precipitation of the arsenic run in. The liquid was now stirred briskly until the precipitate exhibited a tendency to settle, leaving the supernatant fluid clear. The beaker with its contents was next removed from the flame, and ammonia water added to faint but distinct alkaline reaction. This alkaline reaction was removed by the aid of a drop of acetic acid, the liquid again thoroughly stirred, the whole allowed to stand for a few minutes, and, after entire subsidence, the silver arseniate filtered off, washed with pure cold water, dissolved off the filter-paper with a little dilute nitric acid, and the combined silver determined according to Volhard.* I found 0·2572 grm. Ag = 0·0595 grm. As = 0·0785 grm. As_2O_3 = 0·0912 grm. As_2O_5. The method of neutralising the solution is my own.

b. For the two estimations made gravimetrically, and according to my own modification† of the Reich process, I used in each case 10 c.c. The precipitation of the arsenic was made exactly as above described, but instead of dissolving the silver arseniate in nitric acid and titrating the silver, the precipitate was removed from the filter-paper by means of a few drops of ammonia and a little water, the solution caught in a small weighed platinum dish, evaporated to dryness, the residue heated for a short time at 100° C., and then weighed. From the formula Ag_3AsO_4 the arsenic was calculated. I found (1) 0·3661 grm. Ag_3AsO_4 = 0·0592 grm. As = 0·0781 grm. As_2O_3 = 0·0907 grm. As_2O_5; (2) 0·3659 grm. Ag_3AsO_4 = 0·0592 grm. As = 0·0781 grm. As_2O_3 = 0·0907 grm. As_2O_5. Since the molecular weight of Ag_3AsO_4 = 463, and the atomic weight of As = 75, the relation between the two is about 6 : 1, or a difference of 6 m.grms. in the weight of the silver salt will occasion a difference of but 1 m.grm. in the weight of the arsenic. The wonderful degree of accuracy of the method is at once evident. The Levol method gave 0·0591 grm. metallic arsenic; the Reich method 0·0593 grm. of the element in 10 c.c. The difference, 0·0002 grm., is due probably to the solubility of the ammonium magnesium arseniate in ammoniacal water. The figure 0·0593 is undoubtedly the correct one, and we shall in our future work regard it as such.

(To be continued).

LOSS OF AMMONIA ON MIXING SULPHATE OF AMMONIA WITH CALCAREOUS SOIL.

By W. BAXTER.

The loss of ammonia referred to by Mr. Brown in his communication (Chemical News, vol. liii., p. 182) came under my notice a short time ago under circumstances somewhat similar to those which he describes, the substance with which the sulphate of ammonia was mixed in this case being, however, what is known as Navasa guano. My attention was called to the alteration in smell which occurred on this material being mixed with sulphate of ammonia. The suggestion that the alteration resulted from the decomposition of the sulphate of ammonia was soon demonstrated by a few experiments of similar character to those mentioned by Mr. Brown. It was thought that the decomposition might arise from the presence of caustic lime in the guano, and a considerable quantity of lime was found in an aqueous solution of material, but as it was accompanied by sulphuric acid no conclusion to this effect could be drawn from the experiments made, as the lime might all exist as calcium sulphate. The practical conclusion arrived at, however, was that a loss of ammonia must be experienced in mixing sulphate of ammonia with such a fertilising agent.

I may add that the aqueous solution quickly turns reddened litmus-paper blue. It might be of interest to know if an aqueous solution of the soil Mr. Brown experimented with would produce the same effect.

Possibly the presence of a small quantity of an alkaline carbonate may account for the decomposition.

Edinburgh, April 20, 1886.

A NEW METHOD FOR THE DETERMINATION OF PHOSPHORUS IN IRON AND STEEL.*

By J. B. MACKINTOSH, School of Mines, New York.

The general method which has been followed since the time of Heinrich Rose, and perhaps before, for the determination of phosphorus in iron and steel, is to dissolve the sample either in nitric acid, *aqua regia*, or some other oxidising agent, in order to convert the phosphorus into phosphoric acid.

In 1832 Rose† recommends HNO_3, or *aqua regia*, preferably the former. Wöhler, in 1854,‡ directs that the iron should be oxidised by burning in a stream of oxygen for the determination of carbon, and the resulting oxide of iron containing all the phosphorus as phosphoric acid be treated as an ore. In the fourth English edition of Fresenius's "Quantitative Analysis,"§ pp. 666 to 667, we find directions to dissolve the iron in *aqua regia* or bromine; and, coming down to more recent times, we find F. A. Cairns‖ directing the employment of a boiling solution of potassium chlorate and hydrochloric acid for the oxidation and solution of the sample to be analysed. It is unnecessary to multiply quotations from the literature of the subject, though they might be extended almost indefinitely, since it would only be a repetition of the above-mentioned series of methods in one form or another; and the references given have been selected to show how little essential variation there is in the type-methods of solution used. In fact it seems to be universally accepted as a necessary first step in the determination that some such method of solution should be followed.

One chemist, however, struck out on a different line of thought, and to the best of my knowledge only one, M. V. Tantin, who, in a contribution to the *Comptes Rendus* (I have not been able to find the original article, however), copied in the Chemical News,* describes his method for determining phosphorus in cast-iron as follows:—

"When seeking the means of avoiding these sources of error,† I concluded that the best way of so doing would be to use a precisely contrary method, namely, by liberating the phosphorus as a hydrogen compound; but one objection naturally arose—would the totality of the phosphorus pass into the state of a gaseous product? I may safely affirm that I have never been able to discover the least trace of phosphorus in the residue after the complete attack of the cast-iron by chlorhydric acid, which fact is not surprising if it be considered what strong affinities phosphorus has for hydrogen."

According to M. Tantin the resulting gases, composed of phosphuretted, arsenuretted, sulphuretted, and carburetted hydrogen, are passed through potash and then into nitrate of silver, where all the phosphuretted hydrogen is caught as phosphide of silver, which is afterwards treated with *aqua regia*, and the phosphoric acid resulting determined as ammonic-magnesic phosphate. The following precautions are mentioned as indispensable.

1. The cast-iron must be attacked very slowly, or part of the phosphuretted hydrogen may traverse the solution of nitrate of silver without being absorbed.

2. When the solution is finished a current of hydrogen is to be passed through the apparatus.

M. Tantin seems to have overlooked the possibility of some of the phosphorus remaining in the solution, and to have assumed that if none was found in the residue all must have gone off with the gas. If such were the case, the determination of phosphorus would be much simplified.

Some years ago I tried this method on a pig-iron which I knew ran over one per cent of phosphorus, but my final precipitate, if any, of ammonic-magnesic phosphate was so small as to be invisible. I concluded that the method was not suited for American pig-irons, and gave no more attention to the subject till the summer of last year, during which I had considerable leisure time for experiment.

In Watts's "Dictionary of Chemistry"‡ we find the statement, "When a very small quantity of phosphorus is associated with a large quantity of iron, as in many kinds of pig-iron, the whole dissolves in hydrochloric or dilute sulphuric acid, the phosphorus passing into solution as phosphoric acid." This statement is the very reverse of that made by M. Tantin, and to ascertain its accuracy I made the following experiment.

I had just finished an analysis of bar-iron which, by the ordinary method I used,§ had given 0·124 per cent phosphorus. I took 10 grms. of this and dissolved it in hydrochloric acid, finally boiling the solution, neutralised with ammonia, and, after adding a few c.c. of permanganate to oxidise a little iron, precipitated basic acetates, boiling the filtrate twice for further precipitates; the combined precipitates were dissolved in hydrochloric acid, oxidised with nitric, precipitated with ammonia, and the precipitate re-dissolved in nitric acid, and the phosphorus pre-

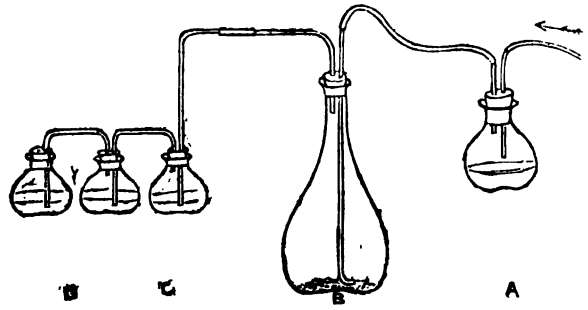
† Loss as phosphuretted hydrogen; estimation of arsenic as phosphorus; and errors due to a large bulk of solutions employed.

‡ 1886, vol. iv., p. 519.

§ Ten grms. dissolved in 120 c.c. nitric acid, sp. gr. 1·20, evaporated to dryness, and heated in air-bath to 120° to 130° C. several hours, re-dissolved in hydrochloric acid, reduced with ammonium bisulphite: precipitate the phosphoric acid by a basic acetate separation, boil the filtrate twice for further precipitates, making three in all, dissolve the combined precipitates in hydrochloric acid, filter out silica, oxidise solution with nitric acid, precipitate with ammonia, re-dissolve the precipitate in nitric acid, and precipitate with ammonic molybdate. This last precipitate is re-dissolved in ammonia and re-precipitated by nitric acid, is then filtered on a Gooch crucible, dried and weighed, and afterwards checked by precipitation as ammonic-magnesic phosphate.

cipitated with ammonium molybdate, finally weighing the yellow precipitate. The result I obtained by this method, was 0·122 per cent, which is a very satisfactory confirmation of the statement the experiment was meant to verify. The time taken in this determination was about from 5 to 6.30 p.m. one evening, by which time I had the yellow precipitate formed,* and the time necessary to filter and weigh the precipitate the next day, perhaps an hour more.

This result being so satisfactory I treated some filings of a high phosphorus pig (in which by my ordinary method I had found 0·826 per cent) in the same manner, but found that I had only succeeded in obtaining 0·580 per cent, or about five-sevenths of the total amount present. I also prepared a button of very high phosphorus iron, and on treating in the same way found that I only obtained about three-quarters of the amount present. This made me think that probably the loss was due either to the escape of phosphuretted hydrogen or to the formation of some other compound than phosphoric acid. I therefore arranged a simple apparatus, the same, in fact, which I use for the determination of sulphur in iron, which is filled with an atmosphere of hydrogen throughout the operation, and consists of a flask A to hold the acid, a flask B for the iron, and flasks C and D, of which C is generally left empty to catch condensed steam, and the two flasks D contain the absorbent liquid.



The absorbent liquid in D was a solution of potassium permanganate acidified with nitric acid. The iron having been placed in B, and the necessary amount of dilute hydrochloric acid to dissolve it in A, the whole apparatus was filled with hydrogen, a current of which was kept passing through the whole time. When the air was all expelled the flask A was inverted above the level of B, so that its contents flowed into B and the solution of the iron commenced. The solution was heated to boiling for some minutes, and when all had dissolved, with the exception of the insoluble portion, the apparatus was disconnected, the insoluble residue filtered from the solution, the solution divided into equal parts, one of which was oxidised with nitric acid and treated as in an ordinary determination of phosphorus, while the other was immediately precipitated by basic acetate, as in the first experiment described.† The amounts of phosphorus found in the prepared iron phosphide were distributed as below.

		Per cent.	Per cent
In residue		3·79	
In solution	oxidised with nitric acid	2·66	
	basic acetate direct		2·16
In gas		0·05	
		6·50	

Showing a loss of 0·50 per cent of phosphorus in the solution in some other form than phosphoric acid. It is very possible that nitric acid fails to oxidise to phosphoric acid all the phosphorus compounds formed in the solution. Referred to the total amount of phosphorus found (6·50 per cent) the distribution per cent is as follows:—

In residue	58·31
Recovered from basic acetate precipitation	33·23
Loss	7·69
In gas	0·77

I repeated the above process on a sample of pig-iron said to contain 0·885 per cent phosphorus, and in which, by my usual method, I found 0·880 per cent weighing as magnesia pyrophosphate, or, calculating from the weight of the yel ow precipitate, 0·878 per cent. This was also conducted in a hydrogen atmosphere. The gas was caught in permanganate acidified with sulphuric acid in the first flask and with nitric acid in the second. Nearly all the phosphorus in the gas was retained in the first flask, a very small amount only passing over to the second. The results obtained were—

Phosphorus in residue		0·345	p.c.
In solution	basic acetate precipitate	0·451	,,
	loss	0·065	,,
In gas		0·019	,,
		0·880	,,

The distribution of the phosphorus is—

In residue		39·11	p.c.
In solution	basic acetate precipitate	51·13	,,
	loss	7·60	,,
In gas		2·16	,,
		100·00	

I then took a sample of high phosphorus pig in which I had found in the usual way 1·45 per cent (weighed as yellow precipitate), or 1·48 per cent (weighed as magnesia pyrophosphate), and dissolved 1 grm. in 10 c.c. hydrochloric acid and 30 c.c. water, finally heating the solution to boiling. This time, instead of a stream of hydrogen being passed through the apparatus, a stream of oxygen was employed. The escaping gas was passed through permanganate and nitric acid. All the phosphorus caught was found in the first flask.

The residue, as in all these experiments, was heated with nitric acid and potassium chlorate; the solution was partially oxidised with 10 c.c. permanganate (1 c.c. = 0·1 Fe) and precipitated as basic acetate as usual; the silica separated from both portions, and the phosphorus determined. The total amount of phosphorus found was 1·42 per cent weighed as magnesia pyrophosphate, or 1·37 per cent weighed as the yellow precipitate, showing a loss of 0·06 per cent. The distribution of the phosphorus was—

In residue		37·47	p.c.
In solution	basic acetate precipitate	55·20	,,
	loss	4·05	,,
In gas		3·28	,,
		100·00	

I next took 2 grms. of the 0·880 to 0·885 per cent pig and dissolved it, as in the last case, in a stream of oxygen,

* I did not seek to remove silica by evaporation to dryness. Per cent Si = 0·151.

† Care being taken to remove silica wherever present.

but, instead of following up each portion separately, mixed them all together (the gas was caught in sulphuric acid permanganate), and collected the residue with the first basic acetate precipitate, treated with nitric acid and potassium chlorate, and proceeded as before. The phosphorus found was only 0·771 per cent, or of the total amount present, 87·41 per cent was found and 12·59 per cent lost.

I repeated the last experiment, using, however, dilute sulphuric acid in place of hydrochloric as the solvent, a stream of oxygen passing continually through, and the solution being kept boiling for fifteen minutes, after all visible action had ceased. The total phosphorus found was 0·767 per cent, distributed as follows:—

In residue		14·17
In solution	basic acetate precipitate	70·86
	loss	13·16
In gas		1·81
		100·00

(To be continued).

PROCEEDINGS OF SOCIETIES.

ROYAL INSTITUTION OF GREAT BRITAIN.

Annual Meeting, Saturday, May 1, 1886.

Sir FREDERICK BRAMWELL, F.R.S., Honorary Secretary and Vice-President, in the Chair.

The Annual Report of the Committee of Visitors for the year 1885, testifying to the continued prosperity and efficient management of the Institution, was read and adopted. The real and funded property now amounts to above £85,000, entirely derived from the contributions and donations of the members.

Twenty-six new Members paid their Admission Fees in 1885.

Sixty-three lectures and nineteen evening discourses were delivered in 1885.

The books and pamphlets presented in 1885 amounted to about 354 volumes, making, with 464 volumes (including periodicals bound) purchased by the Managers, a total of 818 volumes added to the library in the year.

Thanks were voted to the President, Treasurer, and the Honorary Secretary, to the Committee of Managers and Visitors, and to the Professors for their valuable services to the Institution during the past year.

The following gentlemen were unanimously elected as officers for the ensuing year:—

President.—The Duke of Northumberland, K.G., D.C.L., LL.D.

Treasurer.—Henry Pollock.

Secretary.—Sir Frederick Bramwell, F.R.S.

Managers.—Sir Frederick Abel, C.B., D.C.L., F.R.S.; Sir William Bowman, Bart., LL.D., F.R.S.; Joseph Brown, Q.C.; Sir James Crichton Brown, M.D., LL.D., F.R.S.; William Crookes, F.R.S.; Henry Doulton; Sir William Withey Gull, Bart., M.D., D.C.L., F.R.S.; Right Hon. The Lord Halsbury; William Huggins, D.C.L., LL.D., F.R.S.; Alfred Bray Kempe, M.A., F.R.S.; Sir John Lubbock, Bart., M.P., D.C.L., LL.D., F.R.S.; Hugo W. Müller, Ph.D., F.R.S.; Sir Frederick Pollock, Bart., M.A.; John Rae, M.D., LL.D., F.R.S.; Lord Arthur Russell.

Visitors.—Shelford Bidwell, M.A.; Stephen Busk; Michael Carteighe, F.C.S.; Arthur Herbert Church, M.A., F.C.S.; Vicat Cole, R.A.; William Henry Domville; James Edmunds, M.D., F.C.S.; Charles Hawksley M.I.C.E.; Alfred Gutteres Henriques, F.G.S.; David Edward Hughes, F.R.S; George Matthey, F.R.S.; John W. Miers; Lachlan Mackintosh Rate, M.A.; William Chandler Roberts-Austen, F.R.S.; Alexander Siemens.

CHEMICAL NOTICES FROM FOREIGN SOURCES.

NOTE.—All degrees of temperature are Centigrade unless otherwise expressed.

Comptes Rendus Hebdomadaires des Séances, de l' Académie des Sciences. Vol. cii., No. 16, April 19, 1886.

Do the Fluorescences of Zα and Zβ belong to different Earths?—Lecoq de Boisbaudran.—See p. 217.

The Yα of M. de Marignac is definitively named Gadolinium.—Lecoq de Boisbaudran.—M. de Marignac has requested the author to announce to the Academy that he has selected the name gadolinium—symbol Gα—for the metal of Yα.

Thermo-Electricity of Silver Iodide.—H. Le Chatelier.—As a sequel to the sudy of the dimorphism of silver iodide undertaken by the author and M. Mallard he has now examined the corresponding variations in the thermo-electric properties of this body. Melted silver iodide was run in a thin sheet between two silver crucibles, the one containing paraffin and the other water, the temperature of which could be made to vary at pleasure. Each crucible was connected to one extremity of a Deprez D'Arsonval galvanometer. The cubic silver iodide has a much greater conductivity than the hexagonal variety.

On Ammonium Vanadiates.—A. Ditte.—The author describes five of these salts, a neutral or mono-vanadiate, a sesqui-salt which contains 4 or 6 mols. of water according to the temperature at which they are deposited, a di-salt, containing 3 mols. of water, and two tri-salts, a yellow and a red modification, the former of which is the most stable and the most readily formed of all the acid vanadiates. The red salt contains 5 mols. of water. The ammonium vanadiates may be divided into two groups; the former hydrated, deep red, and very soluble in water; the other group anhydrous, slightly coloured, and sparingly soluble. The properties of these bodies seem connected respectively with those of vanadic acid, the soluble red salts containing the soluble variety of this acid, whilst the slightly coloured and slightly soluble compounds contain the polymerised variety which is only sparingly soluble in water.

Transformation of Chromium Monochloride into Sesquichloride. Mechanism of the Solution of Anhydrous Chromium Sesquichloride.—M. Recoura.—The transformation may be effected either by oxidising the monochloride with free oxygen, so as to form the oxychloride, and treating the latter compound with hydrochloric acid. If the solution of monochlotide is saturated the blue-grey sesquichloride is obtained, a blue-grey powder containing 13 mols. of water. The second process consists in passing a current of air into a refrigerated mixture of the solid monochloride and of hydrochloric acid from which the green sesquichloride is precipitated by means of a current of gaseous hydrochloric acid. A third process is to form a dilute solution of chromium monochloride and to pass into it a current of chlorine free from oxygen.

An Acid Fermentation of Glucose.—M. Boutroux.—The ferment required is a micrococcus much resembling *M. oblongus*. It acts only upon glucose. The author describes the calcium, strontium, and cadmium salts of the acid. The comparison between this acid and the hexepic acid of M. Maumené is difficult.

Biedermann's Central Blatt fur Agrikultur Chemie. Vol. xv., Part 1.

Injury to Fisheries and Fish-Culture by Sewage and Industrial Waste Waters.—C. Weigelt, O. Sacre, and L. Schwab.—The authors have made a series of very valuable experiments on this subject, which in England would have been rewarded with heavy fines, if not with imprisonment. They find that chloride of lime in proportions of 0·04 to 0·005 per cent chloride have an immediate deadly action upon tench, whilst trout and salmon perish in presence of 0·0008 per cent of chlorine. Sulphurous acid has the same action as chlorine, and is still more hurtful if another acid is simultaneously present. Sulphites are harmless. Hydrochloric acid, 1 per cent, kills tench and trout. In sulphuric acid of 0·1 per cent trout turn on their sides in two to six hours, whilst tench were not affected in eighteen hours. Acids are said to have less action the higher are their molecular weights (?) Tannin at 0·1 per cent is harmless. Ammonia exerts no action at 0·01 per cent. Soda at 1 per cent is fatal to trout on prolonged exposure. Manganese chloride at 5 per cent had no action on tench in twenty-two hours, and a trout sustained 1 per cent for five hours. Iron acts as a specific poison upon fishes, not only in the state of a ferrous salt. Alum has the same injurious action as the salts of iron. Solution of caustic lime has an exceedingly violent action upon fishes, due in part to the deposition of calcium carbonate in the gills. Arsenious acid, 0·1 per cent, combined with soda has no injurious action upon trout and tench. Mercuric chloride in proportions of 0·1 and 0·05 per cent, is immediately fatal. Copper sulphate, 0·1 and 1·0 per cent, kills trout in a few minutes if they cannot escape into pure water. Potassium cyanide, 0·01 and 0·005 per cent, is rapidly fatal if there is no escape. Potassium sulphocyanide and ferrocyanide in the proportion of 1 per cent had no injurious action in an hour. Sodium sulphide, 0·1 per cent, was endured by tench for thirty minutes. The fish were strongly bleached and did not recover their colour in pure water. Hydrogen sulphide proved rapidly fatal in the proportions of 0·01 and 0·001 per cent. The hurtfulness of putrid sewage depends on poisonous gases, on the deficiency of oxygen, and on the action of bacteria.

Natural Enemies of Rimpau's "Moor-dam" Cultivation.—M. Fleischer and others.—This voluminous memoir does not admit of useful abstraction.

Preservation of Farm-Yard Manure.—Hickethier and Holdefleiss.—Such manure in course of time loses nearly one-third of its organic matter. This loss is reduced by the presence of phosphatic gypsum, but is still considerable. Kainit reduces the loss still further

Gilchrist Slags and their Importance for the Manure Trade.—Prof. Wagner.—At present prices finely ground slags are very advantageous as compared with superphosphate. The Gilchrist precipitates and the Gilchrist superphosphate have no future, as their market value does not cover the cost of production.

A Manurial Experiment with Gilchrist Slag on Oats.—H. Bieber.—The ground slag should be applied to the soil as early as possible.

Animal and Vegetable Pepsine.—O. Schade.—Papayine, the only vegetable pepsine hitherto obtained, is moderately widely diffused and occurs in the so-called carnivorous plants.

Calorimetric Researches.—Prof. F. Stohmann and M. Rübner.—From the *Journal für Prakt. Chemie* and the *Zeitschrift für Biologie*.

The Changes in Fodder Plants in Silos.—Prof. Kellner and J. Sawano.

Utilisation of Certain Foods in the Human Digestive System.—H. Malfatti.—The author's experiments refer to maize-meal alone, in conjunction with butter and with cheese. The latter admixture gave the best results.

Experiments with Sheep on the Digestibility of certain Foods.—Dr. O. Kellner.—Not capable of useful abstraction.

Nitrogenous Ingredients of Pumpkin Seedlings.—E. Schulze.—From the *Journal für Prakt. Chemie*.

Amphoteric Reaction of Plant-Juices.—C. Kraus.—It was found in twenty-one different species of plants that the juices of the pith-parenchyma may be either purely acid, purely alkaline, or amphoteric.

Comparative Researches in various Plant-Seeds on the Formation of Amides on Germination in the Dark.—Drs. Schulze and Flechsig.—In the cereals the order of succession according to the strength of the formation of amide is: rye, oats, barley, wheat. Plant-seeds do not produce quantities of amides proportional to their nitrogenous reserves.

Berichte der Deutschen Chemischen Gesellschaft zu Berlin Vol. xix., No. 2.

Abscission of Hydrocarbons from the Aromatic Sulpho-Acids by means of Superheated Steam.—Werner Kelbe.—The author refers to the researches in this direction of H. E. Armstrong (*Chem. Soc. J.*, 1884, i., pp. 148 to 153) and K. E. Schulze (*Berichte*, xvii., p. 2862) and states that by using superheated steam instead of steam at 100° he has not only succeeded in splitting off the hydrocarbons from the salts of all the aromatic sulphonic acids—adding the necessary quantity of sulphuric acid—but also of decomposing the free dry sulphonic acids in an analogous manner.

On β-Benzoyl-isosuccinic Acid.—C. A. Bischoff.—The synthesis of this acid, described by W. Knes and C. Paal (*Berichte*, xviii., 3323), was effected by the author three years earlier, and is communicated in *Berichte*, xvi., p. 1044.

Chemical Composition of certain Rare Minerals from Hungary.—L. Sipöcz.—The author describes the sylvanite of Offenbanya, the krennerite and nagyagite of Nagyag, the wolframite of Felsöbánya, the wehrlite of Deutsch-Pilsen, the nickel ore of Urawitza, the grey nickel ore and the red nickel of Dobsina, the semseyite of Felsöbánya, the zinc-blendes of Kapnik, Nagyag, Rodna, and Schemnitz, and the bournonite of Nagyag. None of these minerals contain any rare or novel elements.

The Condensation-Products of Pyrrol with Alloxan.—G. Ciamician and P. Magnaghi.—The authors obtain a pearl-grey crystalline substance, insoluble in ether, benzol, petroleum ether, and cold water, but soluble in boiling water with a blue colour. Its composition is the sum of a mol. pyrrol and a mol. of alloxan.

Bases of Methyl Violet and of Magenta.—H. Wichelhaus.—Methyl violet prepared from pure dimethylaniline is a mixture containing among other bases that which was first formed by the action of chloranil upon dimethylaniline, and is distinguished by its crystalline tendency; a non-crystalline product, insoluble in petroleum ether, and soluble in hydrochloric acid with a reddish violet colour.

Supposed Error in working with the Nitrometer.—G. Lunge.—A reply to Mr. T. Bayley's paper (Chem. News, vol. liii., p. 6). If on repeating Bayley's experiment the beaker is well washed out before pouring in the water for the dilution of the nitrometer acid, no more gas is obtained in the nitrometer, but if this precaution is entirely or partially omitted (and it is not mentioned by Bayley) occasionally much more gas may be obtained.

Contributions to a Knowledge of the Alkylendiamines.—A. T. Mason.—The author examines in how far the reactions of ethylendiamine and the kindred diamines agree with those of the aromatic orthodiamines.

A Homologue of Rhodanic Acid.—J. Berlinerblau.—On bringing in contact a strong aqueous solution of

ammonium sulphocyanide with α-chloropropionic acid and applying a gentle heat there is a brisk reaction, and a compound is formed composed of $C_4H_5NS_2O$, iodorous, of a faint yellow colour, and fusible at 123°.

On Rhodanic Acid.—J. Ginsburg and S. Bondzynski.—This very extensive paper does not admit of useful abstraction.

Constitution of Hydrated Salts according to their Vapour-Tension at the Ordinary Temperature.—W. Müller-Erzbach.—An investigation of hydrated haloid salts in continuation of the author's researches published in *Wiedemann's Annalen*, vol. xxiii., p. 607.

Crystals of Venous Hæmoglobine.—M. Neucki and N. Sieber.—The crystals appear as hexagonal plates, some of which have the size of 2 to 3 m.m. In the microspectroscope each crystal displays only the one band of reduced hæmo-globine. The prismatic crystals are doubly refractive.

Alfred Einhorn's Memoir "On an Aldehyd of the Chinoline Series containing the Aldehyd Group in the Pyridin-Nucleus."—W. v. Miller and J. Spady.—The authors point out the discrepancies of their results (*Berichte*, xviii., p. 3402) and those of Einhorn (*Berichte*, xviii., 3465).

On α-Chlorophthalic Acid.—J. Guareschi.—This acid forms long colourless silky needles, fusible at 184°; 2·16 parts of the acid dissolve in 100 parts water at 14°.

Notes.—E. Noelting.—These notes refer to α-iodonaphthaline, trinitro-metacresol, the identity of isorcine and cresorcine, and the nitration of benzylchloride.

On Xylidine-sulphonic Acids.—E. Noelting and O. Kohn.—The substance of this paper has been already published in the *Transactions of the Société Industrielle de Mulhouse* as far back as 1883.

Nitro-derivatives of Paraxylol.—E. Noelting and C. Geissmann.—An investigation into the constitution of the two dinitro-paraxylols. The authors have arrived at the same conclusions as Lellmand, whose researches have, in their opinion, decided the question.

On Meta- ann Para-phenylen-diphenylketon.—E. Noelting and O. Kohn.—These compounds are also known as iso-and terephthalophenon. Both these bodies are diketones and not lactones. It seems probable to the authors that all bibasic acids in which two carboxyls are connected to adjacent atoms of carbon form non-symmetric chlorides.

Azo-derivatives of Metaxylenol.—E. Grevingk.—If metaxylenol is brought in contact with diazobenzolchloride in an alcoholic solution there is formed a brown-red tarry mass, which after re-crystallisation appears in the form of brownish red crystals, phenyl-azometaxylenol—and ortho-oxyazo-compound. Its sulpho-acid dyes wool and silk a brownish yellow in an acid bath.

On Ethyl-paraphenylen-diamine.—W. Schweitzer.—This compound was obtained as a pale yellow, inodorous oil, turning brown and thick on exposure to the air. Its boiling-point at a pressure of 746 m.m. is between 261° and 262°. The base is readily soluble in benzol, alcohol, and ether, less readily in water. If oxidised along with phenoles, ethyl-paraphenylen-diamine yields fine colouring-matters of the indophenol class. That obtained from phenol forms a deep blue powder, and in a curdled soap-beck dyes silks a fine dark blue. With α-naphthol there is formed an analogous colour, which dyes silk a dark cornflower blue. The colour obtained from β-naphthol dyes a more reddish shade, whilst the oxidation-product from resorcine gives a black-blue.

On the Safranines.—W. Schweitzer.—The author describes two isomeric compounds, α- and β-ethylsaffranine. The former is obtained by taking 10·4 grms. of ethyl-paraphenylen-diamine and 12·7 of aniline, both as hydrochlorates, dissolving in 700 c.c. of water, and heating to a boil, with the addition of a little glacial acetic acid. The mixture is stirred and a solution of potassium dichromate, containing 40 grms. per litre, is gradually added. From time to time small portions are taken out of the vessel and moistened with a drop of the oxidising agent upon filter-paper. The colour of the mixture is at first blue, then green, and passes to a reddish violet. A red colour along the margins of the vessel shows the formation of saffranine. After the consumption of 400 c.c. of the bichromate solution a portion of the mixture when touched with a drop of the bichromate remained unchanged. Milk of lime is then added and the red solution of saffranine is separated by filtration from the dark residue and from a violet colouring-matter. The liquid is evaporated to dryness and the colouring-matter is extracted with absolute alcohol at a boil. The β-modification is made with 10·8 grms. paraphenylen-diamine, 7·7 grms. aniline, and 12·3 grms. ethyl-aniline dissolved as hydrochlorates in 500 c.c. water and treated as above. The two ethyl-saffranines are not identical. The isomerism of the colouring-matters appears in particular after they have been fixed upon silk. If silk is dyed with the two hydrochlorates in a curdled soap-beck under the same conditions the tinctorial power of α is found decidedly greater than that of β. The α variety dyes darker with a bluish cast; whilst the β gives lighter, more yellowish tones.

On the Hydroxylamine Reaction.—F. Münchmeyer.—The author obtains results differing from those of Noelting and Kohn, reproduced in No. 1 of the *Chemiker Zeitung* of this year (Jan. 3) from the *Transactions of the Industrial Society of Mulhouse*.

Specific Rotatory Power and Crystalline Form of Glucosamine Hydrobromate.—F. Tiemann.—The results are given in the form of tables.

Alleged Optical Rotatory Power of Picoline.—H. Landolt.—The author's results show the inactivity of picoline. The rotatory angle of from 0·26° to 1° found by Hesekiel and Wiedel lies within the limit of possible error.

The Trioxime of Phloroglucine.—Adolf Baeyer.—Benzol derivatives can be converted into derivatives of hexa-hydrobenzol, not merely as it was supposed by the addition of chlorine, hydrogen, &c., but by simple translocation.

On Juglon.—August Bernthsen and August Semper.—Not suitable for abstraction.

Action of Bromine and Water upon Levulose.—M. Honig.

Action of Caustic Potassa upon Boiling Pyrrol.—G. Ciamician and M. Donnstedt.—The result is the formation of pyrrol potassium, as it was found some years ago by Anderson, though the observation has remained unnoticed. Caustic soda under the same conditions has no action upon pyrrol.

On Meta-nitro-paratolyl-glycine, its Reduction-Product, "Oxy-dihydro-toluquinoxaline," and Meta-nitro-paratoluylic Nitrile.—R. Leuckart.—The author announces that A. Herrmann, in the laboratory of Göttingen University, has been engaged with researches similar to those of O. Hinsberg before the first results of the latter were published.

Certain Derivatives of β-Naphtho-quinone.—R. Koreff.—The author examines the silver salt of β-naphthoquinon-dioxime, mono-methyl-ether, the α-methyl-ether of β-naphtho-quinon-dioxime, the action of hydroxylamine upon the methyl-ether of β-nitroso-α-naphthol, the reduction of β-naphtho-quinon-dioxime, diphenyl-naphthoquinoxaline, diphenylen-naphthoquinoxaline, the oxidation of β-naphtho-quinon-dioxime, and the oxidation of β-diphenyl-glyoxime.

A Disulph-acid of Thiophene and the Corresponding Dicarbonic Acid.—Hugo Jæckel.—This bulky memoir does not admit of useful abstraction.

Experiments on Hydroxylisation of Pyridin-Derivatives in the Lateral Chain.—J. Messinger.—The author has studied the action of hypochlorous acid upon non-saturated compounds of the pyridin series in order to arrive at hydroxylised pyridin derivatives in the lateral chain, as such bodies might be closely related to certain alkaloids.

On Meta-nitro-dimethyl-aniline, Meta-nitro-diethyl-aniline, and their Reduction-Products.—A. Groll.—The author studies here the nitration of dimethylaniline and diethylaniline, and the action of nascent hydrogen upon meta-nitro-dimethylaniline and meta-nitro-diethyl-aniline.

MISCELLANEOUS.

Course of Practical Geology.—Prof. H. G. Seeley, F.R.S., is about to conduct a course of Field Lectures on Saturday afternoons for practical study of the geology of the country round London. This course is given at the request of students of the University Extension Lectures, and information concerning places to be visited may be obtained from Mr. Nicol Brown, 7, Princess Road, Brownswood Park, South Hornsey, N.

New Method of Preserving and Economising Hops Destined for Use in Breweries.—Louis Bouté.—The author's process consists in the mechanical separation of the lupuline, which adheres to the base of the bracts forming the cone of the hop-flower; in obtaining from the bracts thus deprived of lupuline an extract by lixiviation with boiling distilled water. This extract is then dried in a vacuum at a low temperature and is then intimately mixed with the powdered lupuline.—*Comptes Rendus*, vol. cii., No. 14.

On the Cerium Tungstates and Chlorotungstates.—P. Didier.—The action of sodium tungstate upon melted cerium chloride gives rise, not to crystalline sodium tungstate, but to a series of chlorinated compounds, the cerium chlorotungstates. True cerium tungstates were obtained by taking an acid sodium tungstate in a state of fusion and throwing into it ceroso-ceric oxide in small portions, not sufficient to neutralise the excess of acid. A crystalline powder is then separated by water, consisting of octahedra very analogous to the crystals of Scheelite. The author has obtained cerium molybdate in an analogous manner, but he has not succeeded in obtaining a definite cerium chloro-molybdate.—*Comptes Rendus*, vol. cii., No. 14.

MEETINGS FOR THE WEEK.

MONDAY, 10th.—Society of Arts, 8. (Cantor Lectures). "Animal Mechanics," by Dr. B. W. Richardson, F.R.S.
TUESDAY, 11th.—Institution of Civil Engineers, 8.
—— Royal Medical and Chirurgical, 8.30.
—— Photographic, 8.
—— Royal Institution, 3. "The Function of Circulation," by Prof. Arthur Gamgee, F.R.S.
—— Society of Arts, 8. "Japanese Art Work," by Ernest Hart.
WEDNESDAY, 12th.—Society of Arts, 8. "The Proposed Fishery Board," by J. W. Bund Willis-Bund.
—— Geological, 8.
—— Microscopical, 8.
THURSDAY, 13th.—Royal, 4.30.
—— Mathematical, 8.
—— Royal Institution, 3. "The Alkaloids," by Prof. Dewar, F.R.S.
—— Society of Arts, 8. "The Scientific Development of the Coal-Tar Colour Industry," by Professor R. Meldola.
FRIDAY, 14th.—Royal Institution, 9. "Suspended Crystallisation," by Prof. J. M. Thomson.
—— Quekett Club, 8.
—— Astronomical, 8.
SATURDAY, 15th.—Royal Institution, 3. "How to Form a Judgment on Musical Works," by Prof. Ernst Pauer.
—— Society of Arts, 3. "Electricity," by Professor George Forbes.

TO CORRESPONDENTS.

C. C. Robertson.—Lomas, "Manual of Alkali Trade" (Crosby Lockwood and Co.), and Lunge's great work on "Sulphuric Acid and Alkali," vol. iii. (Van Voorst), give full information on bicarbonate of soda. Epsom salts are briefly described in "Ure's Dictionary." They are not mentioned in "Spon's Encyclopædia," and we do not even know of a German work which goes into their manufacture.

NEW VOLUME OF CHURCHILL'S TECHNOLOGICAL HANDBOOKS. With Engravings, crown 8vo., 7s. 6d.

OILS AND VARNISHES. Edited by JAMES CAMERON, F.I.C., Analyst in the Laboratory, Somerset House.
J. and A. CHURCHILL, 11, New Burlington Street.

MANCHESTER CORPORATION GAS-WORKS.

TAR AND AMMONIACAL LIQUOR.

The Gas Committee of the Manchester Corporation are prepared to receive Tenders for the purchase and removal of the Tar and Ammoniacal Liquor to be produced at their Droylsden Station during the period of one or more years from the 24th June next. The Committee do not bind themselves to accept the highest or any Tender. Sealed Tenders, addressed to the Chairman of the Gas Committee and endorsed "Tender for Tar and Liquor, Droylsden," must be delivered at the Offices of the Gas Department, Town Hall, on or before Monday, the 24th day of May next. Forms of Tender and further particulars may be obtained on application in writing to Mr. CHARLES NICKSON, Superintendent of the Department.

By order of the Gas Committee,
Town Hall, April 30, 1886. JOS. HERON, Town Clerk.

MANCHESTER CORPORATION GAS-WORKS.

SPENT OXIDE.

The Gas Committee of the Corporation of Manchester are prepared to receive Tenders for the purchase and removal of the Spent Oxide to be produced at their Gaythorn, Rochdale Road, and Bradford Road Works during a period of one, two, or three years, from the 30th June next. The Committee do not bind themselves to accept the highest or any Tender. Sealed Tenders, addressed to the Chairman of the Gas Committee and endorsed "Tender for Spent Oxide," must be delivered at the Offices of the Gas Department, Town Hall, on or before Monday, the 24th day of May next. Forms of Tender and further particulars may be obtained on application in writing to Mr. CHARLES NICKSON, Superintendent of the Gas Department.

By order of the Gas Committee,
Town Hall, April 30, 1886. JOS. HERON, Town Clerk.

THE WORCESTER CHEMICAL MANURE WORKS, DIGLIS, WORCESTER.

Messrs. FULLER, HORSEY, SONS, and CASSELL are instructed to SELL by AUCTION, at the Mart, Tokenhouse Yard, London, E.C., on Wednesday, June 9th, at 2 precisely, the WORCESTER CHEMICAL WORKS, Diglis, situate on the banks of the Worcester and Birmingham Canal, close to its junction with the River Severn. The buildings are of modern construction and well arranged, and comprise a brick-built factory and manure store, over which are three large lead chambers, with match-boarded enclosure and slated roof, a Gay-Lussac tower, 60 ft. high, and a Glover's tower, 55 ft. high, large ranges of stores, grinding room, steam-engine and boiler houses, chimney shaft, offices, and laboratory. The plant and machinery include two Carr's patent disintegrators, phosphate breaker, five pairs 4 ft. 6 in. French burr mill stones, two steam engines and boilers, and the necessary appliances for carrying on a large business. The works are capable of turning out 50 tons per diem, and barges of 108 tons can load alongside. They are held for an unexpired term of about 70 years at low rents amounting to £92 8s. per annum, and the total area is upwards of an acre. Possession will be given on completion of the purchase. May be viewed by orders to be obtained of the Auctioneers; and particulars, with plans, may be had of Messrs. John Stallard and Son, Solicitors, Worcester; Messrs. Stallard and Turner, Solicitors, 44, Bedford Row, W.C.; of Messrs. Webb and Exton, Surveyors, The Avenue, Cross, Worcester; at the Mart; and of Messrs. Fuller, Horsey, Sons, and Cassell, 11, Billiter Square, London, E.C.

A CHEMIST
is open to Engagement as
MANAGER.
Scientific training and large practical experience from leading Works of England and Germany.
Apply to Box 777, CHEMICAL NEWS Office, Boy Court, Ludgate Hill, London, E.C.

THE CHEMICAL NEWS.

Vol. LIII. No. 1381.

ELECTROLYTIC CONDUCTION IN RELATION TO MOLECULAR COMPOSITION, VALENCY, AND THE NATURE OF CHEMICAL CHANGE:

Being an Attempt to apply a Theory of "Residual Affinity."*

By HENRY E. ARMSTRONG Ph.D., F.R.S.

In my recent address to the Chemical Section of the British Association at Aberdeen I have specially called attention to the "affinity" of *negative* elements—chlorine, oxygen, sulphur, &c.—for negative elements; and I have sought to show that the formation of so-called *molecular compounds* is largely, if not entirely, an outcome of this peculiarity of negative elements. I have also ventured to suggest "that in electrolysing solutions the friction arising from the attraction of the ions for each other is perhaps diminished, not by the mere mechanical interposition of the *neutral* molecules of the solvent—in the manner suggested by Kohlrausch—but by the actual attraction exercised by these molecules upon the negative ion in virtue of the affinities of the negative radicles." In this passage I but vaguely hinted at a modification of the current theory of electrolysis which had occurred to me; as further consideration of the question, especially of Ostwald's electro-chemical studies, has strengthened my views, I am led to think that it may be justifiable to submit them for discussion.

It is usual to divide bodies into three classes according to the mode in which they are acted on by an electromotive force: metals forming one class, electrolytes a second, and dielectrics a third. In making this division perhaps the fact is not sufficiently borne in mind that some compounds — silver chloride for example — are *per se* electrolytes, while others—such as hydrogen chloride and water—are *individually* dielectrics, but behave as electrolytes when conjoined. On this account it appears to me desirable to distinguish between—

(*a*) *Metals.*

(*b*) *Simple* electrolytes—compounds, like silver chloride which in the pure state are electrolytes.

(*c*) Pseudo-dielectrics—compounds which, like water, hydrogen chloride, and sulphuric acid behave as dielectrics when *pure*, but as electrolytes when mixed with other members of their own class. Conducting mixtures of members of this class may conveniently be termed *composite electrolytes.*

(*d*) Dielectrics.

Simple Electrolytes.

It is undoubtedly a fact that only a limited number of binary compounds are simple electrolytes; and it is especially noteworthy that, with the single doubtful exception of liquefied ammonia, no hydrogen compound—whether binary or of more complex composition—can be classed with the simple electrolytes. Indeed, all the simple electrolytes with which we are acquainted are either compounds such as the *metallic* chlorides or *metallic* salts—nitrates, sulphates, &c. Including metallic chlorides and their congeners and the corresponding oxides and hydroxides among salts—regarding water as an acid, in fact—and denying the title of salts—hydrogen salts—to the acids, Hittorff's proposition (*Weid. Ann.*, 1878, iv., 374): "Electrolyte sind Salze" may be safely upheld. But only some of the binary metallic salts are electrolytes; beryllium chloride, for example, belongs to the class of "pseudo-dielectrics" (Nilson and Petterson, *Wied. Ann.*, 1878, iv, 565; Humpidge, *Phil. Trans.*, 1883, 604); and in the case of those elements which readily form two classes of salts—so-called *ous* or *proto*-salts and *ic* or *per*-salts, the *ous* compounds alone appear to be electrolytes.

It is highly remarkable that whereas fused silver chloride is easily decomposed on passage of a current of low electromotive force, hydrogen chloride is a "pseudo-dielectric" which forms, when coupled with the "pseudo-dielectric" water a readily conducting "composite electrolyte," while mercuric chloride conducts with great difficulty—possibly not at all when pure—not only in the fused state, but even when coupled with water. No explanation of these facts seems to be afforded by thermo-chemical data.*

The consideration of these and other similar cases, I think, can but lead to one conclusion: that electrolysability is conditioned both by the nature of the elements in the compound and its molecular structure. I have put forward the hypothesis in my address—"that among metallic compounds only those are electrolytes which contain more than a single atom of metal in their molecules." The mere presence of two or more associated atoms of metal in the molecule, however, probably does not constitute a compound an electrolyte; and although the hypothesis may be applicable to the majority of simple electrolytes, it certainly does not appear to include all the facts, and it does not serve to explain why certain salts are electrolytes while others are not.

The remarkable difference in the electrical behaviour of two compounds of the same element, such as stannous chloride, in which the ratio of tin to chlorine atoms is as 1 to 2, and stannic chloride, in which Sn : Cl = 1 : 4—the one being a simple electrolyte, the other a pseudo-dielectric—if indeed it be not a dielectric—would appear almost to justify the conclusion that, in the case of per-salts such as stannic chloride, the metal is, as it were, enveloped in a non-conducting sheath of the negative radicle. But whether this be so or not, if—as appears to be the case—all simple electrolytes are *metallic* compounds, and if only proto-salts are electrolytes, may it not be that electric conduction in simple electrolytes is of the nature of ordinary metallic conduction, differing from it only in the circumstance that the compound is decomposed as a consequence of the passage of the current?

This would lead to the conception of an electrolyte as being a metallic compound of such elements, and so constituted that electric conduction may take place through its mass in a manner similar to that in which it takes place through a mass of metal: in fact through the agency of its metallic atoms. On this view, it is essential that the metallic atoms in the molecules comprising a mass of an electrolyte should be in proximity—as they probably are in proto-salts, but not in many per-salts. The conductivity of two-metal alloys is in many cases much less than that of either of the contained metals: for example, the conductivity of the alloy $SnCu_4$ is about $\frac{1}{4}$th that of tin and about $\frac{1}{10}$th that of copper. The specific conductivity of metals may, therefore, be much reduced by

* A Paper read before the Royal Society, March 25th, 1886.

* The following numbers are given by Thomsen as representing the amounts of heat developed in the formation of the specified chlorides in the state of aggregation in which they exist under ordinary conditions (2 × 35·4 grms. of chlorine being in each case used in the production of the chloride):—

Hydrogen chloride	..	..	44,000 units (grm.° C.).
Silver	,,	.. ..	58,760 ,,
Mercuric	,,	.. ..	63,160 ,,
Stannic	,,	.. ..	63,625 ,,
Stannous	,,	.. ..	80,790 ,,
Lead	,,	.. ..	82,770 ,,

Only three of the chlorides in this list are simple electrolytes. As much more heat is developed in the formation of two of these three—stannous and lead chlorides—than in the case of any of the others, it would appear probable *à priori* that these would be the most stable; obviously, therefore, the study of the heats of formation throws no light on differences in electrical behaviour such as are manifest between hydrogen, mercuric and stannic chlorides, on the one hand, and silver, stannous and lead chlorides on the other.

association with one another; and this being the case, it appears probable that the specific conductivity of a metal would be still more reduced by association with a non-metal, and that if the metal were one of low specific conductivity, it might thus practically become altogether deprived of conducting power; perhaps the exceptional behaviour of mercuric and beryllium chlorides is to be explained by considerations such as these.

To discuss such questions at all satisfactorily, however, we require to know much more of the electrical behaviour of *pure* fused salts; it is surprising how little accurate knowledge we possess on this subject.

Composite Electrolytes.

I assume it to be admitted that neither water nor liquid hydrogen chloride, for example, is an electrolyte, although an aqueous solution of hydrogen chloride conducts freely, and is electrolysed by an electromotive force of but little more than a volt.

The theory put forward by Clausius in 1857, in explanation of electrolysis, is well stated in Clerk Maxwell's "Elementary Treatise on Electricity" (p. 104), in the following words:—

"According to the theory of molecular motion every molecule of the fluid is moving in an exceedingly irregular manner, being driven first one way and then another by the impacts of other molecules which are also in a state of agitation. The encounters of the molecules take place with various degrees of violence, and it is probable that even at low temperatures some of the encounters are so violent that one or both of the compound molecules are split up into their constituents. Each of these constituent molecules then knocks about among the rest till it meets with another molecule of the opposite kind, and unites with it to form a new molecule of the compound. In every compound, therefore, a certain proportion of the molecules at any instant are broken up into their constituent atoms. Now, Clausius supposes that it is on the constituent molecules in their intervals of freedom that the electromotive force acts, deflecting them slightly from the paths they would otherwise have followed, and causing the positive constituents to travel, on the whole, more in the positive than in the negative direction, and the negative constituents more in the negative direction than in the positive. The electromotive force, therefore, does not produce the disruptions and reunions of the molecules, but finding these disruptions and reunions already going on, it influences the motions of the constituents during their intervals of freedom. The higher the temperature, the greater the molecular agitation, and the more numerous are the free constituents. Hence the conductivity of electrolytes increases as the temperature rises."

This theory has been widely accepted by physicists; but it appears to me that, on careful consideration of the evidence, and especially of recent exact observations on conditions of chemical change, it must be admitted, as I have elsewhere contended (B. A. Address), that proof is altogether wanting of the existence of a condition such as is postulated by Clausius. Moreover, it has been shown by Hittorf that cuprous and silver sulphides, and by F. Kohlrausch that silver iodide, all undergo electrolysis in the *solid* state; the partisans of the dissociation hypothesis would, I presume, scarcely contend that it is easily applicable to such cases as these. It also does not appear to afford any explanation of the abrupt change in conductivity which occurs in solid silver iodide and sulphide as the temperature is raised; nor of the peculiar variation in conductivity on diluting sulphuric acid with water.

Again, I venture to think that the conductivity of a *mixture* of compounds which themselves have little or no conducting power is accounted for in but an unsatisfactory and insufficient manner by the hypothesis put forward by F. Kohlrausch (*Pogg. Ann.*, 1876, 159, 233); there appears to be *far too great a difference* in the behaviour of the pure compounds, water and liquid hydrogen chloride, for example, and of a mixture—no decomposition apparently of either *compound* being effected by any electromotive force short of that which produces disruptive discharge, although the *mixture* of the two will not withstand an electromotive force of little more than a volt. Influenced by these considerations, I am led to conclude that there is no satisfactory evidence that the constituents of the electrolyte are either free prior to the action of the electromotive force, or are primarily set free by the effect produced by the electromotive force upon either member *separately* of the *composite* electrolyte; but that an additional influence comes into play, viz., that of the one member of the composite electrolyte upon the other while both are under the influence of the electromotive force. This influence, I imagine, is exerted by the negative radicle of the one member of the composite electrolyte upon the negative radicle of the other member. Assuming, for example, that in a solution of hydrogen chloride in water the oxygen atom of the water molecule is straining at the chlorine atom of the hydrogen chloride molecule, if when subjected to the influence of an electromotive force the molecules are caused to flow past each other—and the phenomena of electric endosmose afford evidence that in composite electrolytes the molecules are thus set in motion—it is conceivable that this influence, superadded to that of the electromotive force upon the electrolyte, may bring about the disruption of the molecule and conduction: in short, that a state may be induced such as Clausius considers is the state prior to the action of the electromotive force.

A large amount of most valuable information on the connection of dilution and electrical conduction in aqueous solutions has been recently published by Arrhenius, Bouty, F. Kohlrausch, and Ostwald. In his most recent paper Ostwald (*Journal für Praktische Chemie*, 1885, 32, 300) has given the results of his determinations of the *molecular conductivity* m* in the case of no less than about 120 different acids; it appears to me that many—indeed all—of his observations afford most distinct evidence in favour of the view I have expressed above. The general result of his investigation is that the molecular conductivity increases with dilution—in other words, that the dissolved substance exercises a greater specific effect, finally attaining a maximum; it then diminishes, but he believes this to be due to impurities in the water, especially to neutralisation of the acid by traces of ammonium carbonate. The maximum, he appears to think, would be the same for all acids if the dilution could only be pushed far enough; in the case of monobasic acids it is about 90 (arbitrary units); it is twice this in the case of dibasic, thrice in the case of tribasic, and so on.

I will quote first his results in the case of solutions of hydrogen chloride, bromide, iodide, fluoride, and silicon fluoride.

TABLE I.

v.	HCl.	HBr.	HI.	HF.	H_2SiF_6.
2	77·9	80·4	80·4	—	47·81
4	80·9	83·4	83·2	6·54	57·29
8	83·6	85·1	84·9	7·59	62·20
16	85·4	86·6	86·4	10·00	67·08
32	87·0	87·9	87·6	13·14	71·52
64	88·1	88·9	88·7	17·38	75·61
128	88·7	89·4	89·4	23·11	79·22
256	89·2	89·6	89·7	30·30	83·39
512	89·6	89·7	89·7	39·11	91·62
1024	89·5	89·5	89·3	49·49	109·5
2048	89·5	88·9	89·0	59·56	144·0
4096	88·6	87·6	87·8	69·42	187·1
8192	—	—	—	—	226·6
16384	—	—	—	—	258·6
32768	—	—	—	—	282·6

It will be observed that hydrogen chloride, bromide, and iodide practically behave alike; the numbers for the chlo-

* $m=kv$, k being the specific conductivity as ordinarily defined, and v the volume of the solution, *i.e.*, the number of litres containing the formula weight in grms. of the acid. His results are expressed in arbitrary units.

ride are, however, slightly lower than those for the bromide and iodide, and the maximum is not reached quite so soon in the case of the chloride. Hydrogen fluoride is altogether different: its molecular conductivity is exceedingly low to begin with, and is considerably below the maximum even when $v=4092$. But I would call special attention to the numbers for hydrogen silicon fluoride, which is commonly regarded as a dibasic acid; at first, as Ostwald says, it behaves as a monobasic acid of moderate strength—iodic acid, for example; but the maximum for monobasic acids being exceeded, the molecular conductivity increases more and more rapidly, ultimately exceeding the treble value, 270. It must be supposed that it undergoes decomposition in accordance with the equation $H_2SiF_6+2H_2O=SiO_2+6HF$. The noteworthy point is *the large excess of water* required to initiate this change; when $v=16$ the solution contains less than 1 per cent H_2SiF_6, and at this point, according to Ostwald, decomposition probably begins, but that it is far from complete, even when a very much larger excess is present, is evident from the fact that the maximum, when $v=32,768$, is 282, and not above 400.

Now it is well known that hydrogen chloride, bromide, and iodide are, practically speaking, perfect gases under ordinary circumstances: in other words, masses of these gases would mainly consist of molecules such as are represented by the formulæ HCl, HBr, and HI. It has been proved, however, by Mallet that hydrogen fluoride at temperatures near to its boiling-point mainly consists of molecules of the formula H_2F_2. In the aqueous solution the molecules would be brought more closely together, and therefore it is probable that, even in the case of hydrogen chloride, bromide, and iodide, a certain proportion of more complex molecules would result; the relatively high boiling-point of hydrogen fluoride (19·4°) renders it probable that in the liquid state this compound would at least partially consist of molecules more complex even than is represented by the formula H_2F_2. On the hypothesis put forward in this paper, the influence exercised by the one member of the composite electrolyte upon the other member during electrolysis is at all events mainly exercised by their respective negative radicles, and the extent of the influence thus mutually exerted by these radicles would depend on the extent to which they are still possessed of "residual affinity." If the hydrogen chloride, bromide, and iodide are present chiefly as simple molecules they should exert, *ab initio*, almost the full effect which they are capable of exerting; and the chief effect of dilution being to decompose the more complex molecules, conductivity should increase to but a slight extent if the extent to which simplification can take place be but small. On the other hand, if owing to the formation of molecular aggregates the residual affinity be more or less exhausted, the initial conductivity will be low, and it will increase on dilution only in proportion as these aggregates become broken up.

It appears to me that the behaviour of the four hydrides under discussion is absolutely in accordance with these requirements of the hypothesis. Even the difference between hydrogen chloride and hydrogen bromide and iodide is not without its bearing. The determinations of the density of chlorine at various temperatures by Ludwig, and of the density of bromine by Jahn (*Monatshefte für Chemie*, 1882, 176), have shown that it is necessary to raise the temperature considerably higher above the boiling-point in order to reduce the density to the theoretical value in the case of chlorine than in the case of bromine: in other words, there is a greater tendency in chlorine to form aggregates more complex than those of the formula Cl_2 than there is in bromine to form aggregates more complex than those of the formula Br_2. It is, therefore, not unlikely that the chlorine in HCl has more "residual affinity" than the bromine in HBr,* and if so the aqueous solution of the former would have a lower initial conductivity than one of equivalent strength of hydrogen bromide, and the maximum would be obtained only on greater dilution; which is precisely the case.

(To be continued).

* On other grounds also there is reason to believe that hydrogen chloride differs more from hydrogen bromide or iodide than either of these differs from the other: thus less heat is developed on dissolving hydrogen chloride in water than on dissolution of equivalent quantities of the bromide or iodide, the numbers given by Thomsen being—

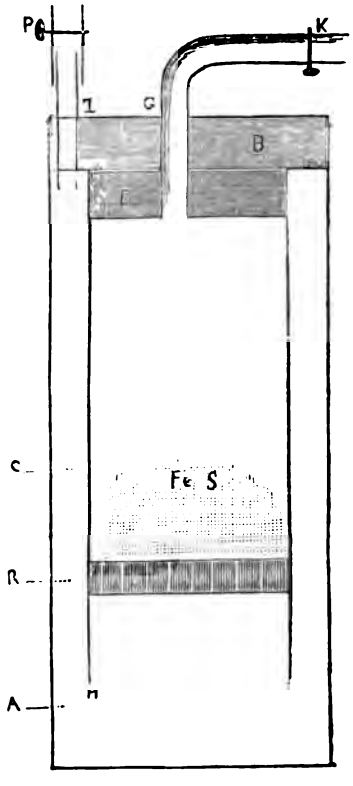
HCl, $400H_2O=17,300$ units.
HBr, $400H_2O=19,200$,,
HI, $400H_2O=19,200$,,

The solution of hydrogen chloride which distils unchanged at 112° at the ordinary pressure has approximately the composition represented by the formula $HCl.8H_2O$; whereas the corresponding solutions of hydrogen bromide and iodide boil at 125° and 127°, and their composition is approximately represented by the formulæ $HBr.5H_2O$ and $HI.5·5H_2O$. A solution of hydrogen fluoride, approximately of the composition $HF.2H_2O$, distils unchanged at 120°.

ON A NEW SULPHURETTED HYDROGEN GAS APPARATUS.

By JOHN J. BARLOW.

THE following is a drawing, with explanation in detail, of a sulphuretted hydrogen gas apparatus which I have been using now for some time, which works well, is simple and easy to make, and does not cost much, and I can by its means always have ready a supply of gas; nor does it give off any offensive odour.



A is a large jar, about 10 inches high and 3 inches in diameter; it is closed at the mouth with a very tight-fitting stopper, B, of indiarubber cut out of ¾-inch thick sheet-rubber, or, if this is not to be had, a good sound cork pushed in tight, about ½ inch below the top of the jar, and then well covered with wax or paraffin. Inside this jar, and fitting close up underneath the stopper B, is

a strong wide tube, about 8 inches long, and 2½ inches in diameter, C. The top end of this tube is also provided with a very tight-fitting stopper. A strong glass tube, G, ½ inch in diameter, passes through both of these two stoppers, one end just protruding about ⅛ inch below the inner stopper; the other end, outside and above the outer stopper, is bent round at right angles, and is connected with a piece of rubber tubing which is provided with a strong clip, K. This tube, G, serves for the exit of the gas, and also supports the inner jar, or tube C; R is a perforated cork, pushed up 1 inch inside the inner tube C; this cork supports the iron sulphide, FeS: *t* is a glass tube passing through the stopper of the outer jar, and is provided with a piece of rubber-tubing and clip, P.

To work the apparatus take out the inner tube, then place the FeS inside the inner jar, and resting on R; then place the tube C inside the jar A, pressing down the stopper B; open G by means of the clip K, remove the india-rubber-tubing from *t*, then insert a small funnel in the tube *t*, and pour in, and, filling the jar to within ½ an inch of the stopper B with dilute H_2SO_4 (1 : 6), remove the funnel; slip on the rubber-tube. Now open both clips, when the acid will rush up inside the inner vessel; close the tubes G and *t*; gas will now form, and will fill the tube C, and at last by its own pressure push out the acid liquid down as far as M, when the action will cease until a supply of gas is required, when the tube G will have to be opened and the liquid will again rush up into C, but will be pushed back again to M when the gas has reached a certain pressure in C.

Radcliffe Close Chemical Works,
Radcliffe, near Manchester, April 29, 1886.

CONTRIBUTIONS TO THE BACTERIOSCOPIC EXAMINATION OF WATER.

By Dr. LINK.

In a publication by Prof. Koch (*Med. Wochenschrift*, 1885, No. 37) on the scope of the bacteriological examination of water, it is asserted that "a large proportion of micro-organisms proves that the water has received putrescent admixtures, charged with micro-organisms, impure affluxes, &c., which may convey, along with many harmless micro-organisms, also pathogenous kinds, *i. e.*, infectious matters." Further, "As far as present observations extend the number of micro-organisms in good waters ranges from 10 to 150 germs capable of development per c.c. As soon as the number of germs decidedly exceeds this number the water may be suspected of having received affluents. If the number reaches or exceeds 1000 per c.c. such water should not be admitted for drinking, at least in time of a cholera epidemic."

The author has examined a great number of the Danzig well-waters chemically and bacterioscopically. The results obtained agree, however, very ill with the above opinions of Koch. On the contrary, it appears very plainly that regular relations between the chemical results and those of the bacterioscopic examination do not obtain. Many well-waters, chemically good and not directly or indirectly accessible to animal pollutions, often contained considerable numbers of microbia, whilst other waters, chemically bad and evidently contaminated by the influx of sewage, showed very small numbers of bacteria undergoing development. If we further consider that, by far the majority indeed, as a rule the totality of the bacteria contained in well-water, are indubitably of a harmless nature, and that when a pollution of the water by pathogenous germs has actually occurred, such germs will not in general find the conditions necessary for their increase, especially a temperature approximating to that of the body and a sufficient concentration of nutritive matter, but that they will rather perish from the overgrowth of the other bacteria inhabiting the water, we shall see that a judgment on the quality of water—according to the results of a bacterioscopic examination extending merely to a determination of the number of germs capable of development—must lead to inaccurate conclusions, which contradict the results of chemical analysis.

The attempt to put forward bacterioscopic examination as a decisive criterion for the character of a water is therefore devoid of a satisfactory basis. For the present the decision must be left to chemical analysis.—*Arch. Pharmacie* per *Chemiker Zeitung*.

CYCLAMOSE, A NEW SUGAR.

By GUSTAVE MICHAUD, D.Sc.

Cyclamose is found in the tubercles of *Cyclamen Europæum*. Its formula, as deduced from its analysis, is $C_{12}H_{22}O_{11}$. This formula is confirmed by the fact that cyclamose can be inverted by diluted acids. The most striking feature of cyclmose is its rotatory power (−15·15), which is left-handed, while all the other sugars in the group $C_{12}H_{22}O_{11}$ are right-handed or inactive. The activity of cyclamose is not affected by temperature, but it decreases under the influence of basic lead acetate. At 65° C. dilute hydric chloride almost immediately increases it, and makes it = −66·54 at 15° C., but this number rapidly decreases under the influence of heat. Like lactose, cyclamose reduces Fehling's solution.

Cyclamose is obtained by leaving for a few days tubercles of *Cyclamen* with weak alcohol (80 per cent). The filtered solution must be concentrated, and mixed with a great excess of strong alcohol (96 per cent), which determinates the formation of a precipitate of sugar. This precipitate is dissolved in water, and mixed with slaked lime. After filtration of the solution alcohol is added to it. The voluminous precipitate which appears is collected in a filter and washed with alcohol; then it is dissolved in water, and a current of carbonic dioxide is sent through it. The filtered solution, evaporated in an air-pump vacuum over a basin containing oil of vitriol, leaves pure cyclamose.

ON THE DETERMINATION OF ARSENIC.*

By LeROY W. McCAY.

(Continued from p. 222.)

The following are the *qualitative* tests made according to Holthof's directions, my object here being, as already intimated, to satisfy myself as to the exact degree of completeness of the reduction of the arsenic from the arsenic to the arsenious state of oxidation. In I., each of the 10 c.c. of H_2KAsO_4 solution taken were mixed in a flask with 50 c.c. sulphurous acid and 100 c.c. water, after which the flask and contents were heated for two hours upon the boiling water bath, then for two hours to incipient boiling upon a little sand-bath, whereupon the liquid was boiled down over a free flame to one-half the original volume; a large platinum spiral with pieces of pumice about the size of hazel nuts, threaded and twisted on each end, being introduced into the flask, partially to prevent bumping, partially to facilitate the disengagement of the sulphur-dioxide gas. In II., double the quantities of sulphurous acid and water used in I. were added; and in III., first the quantities used in I., second those used in II. In each case the liquid remaining after boiling down was emptied into a porcelain dish, evaporated to about 50 to 60 c.c., and tested for arsenic acid, (1) with silver nitrate, (2) with magnesia mixture, and (3) with magnesia mixture after removing the arsenic

* *American Chemical Journal* vol. vii., No. 6.

as the trisulphide with sulphuretted hydrogen in the cold, and displacing the latter with a rapid stream of carbon dioxide. The tests were made in strict accordance with the directions of Fresenius.* In no case was I able to obtain in the 50 to 60 c.c. a decided reaction for arsenic acid. For sake of convenience I arrange the experiments in outline as follows :—

I.

a. 10 c.c. solution, 50 c.c. SO_2 and 100 c.c. H_2O.
b. " " "
a. Reaction for As_2O_5 with $AgNO_3$, none. *b*. Reaction for As_2O_5 with magnesia mixture, none.

II.

a. 20 c.c. solution, 100 c.c. SO_2 and 200 c.c. H_2O.
b. " " "
a. Reaction for As_2O_5 with $AgNO_3$, none. *b*. Reaction for As_2O_5 with magnesia mixture, none.

III.

a. 10 c.c. solution, 50 c.c. SO_2 and 100 c.c. H_2O.
b. 20 c.c. solution, 100 c.c. SO_2 and 200 c.c. H_2O.
a. Reaction for As_2O_5 with magnesia mixture, after separation of As_2O_3, none. *b*. Reaction for As_2O_5 with magnesia mixture, after separation of As_2O_3, none.

These experiments go to prove that the reduction of the arsenic from the arsenic to arsenious state is to all intents and purposes complete, and in consequence thereof they confirm conclusively what Holthof has to say respecting the correctness of his mode of procedure. For quantitative work much experience has led me to believe that the following solutions are probably the most convenient :—

(*a*) $\frac{1}{10}$ *Normal Iodine Solution*.†—Dissolve 6·35 grms. of pure dry iodine with the help of about 10·0 grms. of potassium iodide in a little water, and dilute to a litre.

(*b*) $\frac{1}{10}$ *Normal Arsenious Oxide Solution*.† — Dissolve 2·475 grms. chemically pure arsenious oxide in a little warm potassium hydrate solution, neutralise with hydrochloric acid, and dilute to a litre.

Use for controlling the iodine solution :—

(*c*) *Starch Solution*.‡—Rub up thoroughly in a small porcelain mortar, with 10 c.c. of a solution of pure potassium hydrate of ordinary strength, 2 grms. of starch, and bring into 200 c.c. boiling water. Stir until solution is complete, cool, bottle, and preserve well corked. It will keep indefinitely.

(*d*) *Hydro-sodium Carbonate*.—Dissolve 150 to 200 grms. of the pure salt in 2 litres of water.

(*e*) *Sulphurous Acid*. — Use water *saturated* § with the gas.

Theoretically, 1 c.c. of the above $\frac{1}{10}$ normal iodine should exactly balance 1 c.c. of the $\frac{1}{10}$ normal arsenious oxide, and 1 c.c. = 0·001875 grm. As = 0·002475 grm. As_2O_3 = 0·002875 grm. As_2O_5 ; practically, however, 20 c.c. of the arsenious oxide solution required, in three separate trials, (1) 19·9, (2) 19·9, and (3) 19·9 c.c. of the iodine solution for complete oxidation. Hence 1 c.c. = 0·001884 grm. As = 0·002487 grm. As_2O_3 = 0·002889 grm. As_2O_5.

A. 1.—50 c.c. of the solution H_2KAsO_4, 100 c.c. SO_2, and 150 c.c. water were brought into a flask and heated for two hours upon a boiling water-bath, then for two hours upon a little sand-bath, and finally boiled down to one-half the original volume, a large platinum spiral being introduced into the flask to prevent bumping and facilitate the disengagement of the sulphur-dioxide gas. In all my experiments this boiling down to one-half the original volume (care being of course taken to introduce into the flask the platinum spiral) proved amply sufficient. I have not yet been able to detect any sulphur dioxide in a solution so treated. The solution was allowed to cool, diluted to 300 c.c., and for each of the first lot of estimations below given 30 c.c. for each of the second lot 60 c.c. taken. In titrating care was taken always to work under like conditions, the same quantities of hydro-sodium carbonate, starch, and water being invariably used. The most convenient volume of liquid for titration proved to be approximately 300 c.c. Accordingly, 30 c.c. reduced solution, 20 c.c. hydro-sodium carbonate, and 1 c.c. starch solution being diluted in a larger beaker to 300 c.c., the $\frac{1}{10}$ normal iodine solution was run in until a sky-blue colour resulted. The point of transition is remarkably easy to strike, and the reaction is so sharp and exact that one is never in doubt as to a single drop. The fact, too, that the blue appears shortly before the oxidation is complete, and a little extra stirring is necessary to cause it to disappear, furnishes us with an indication of the approach of the end of the operation, and thereby renders it almost impossible for one to overstep the point.

Four estimations :—

No.	Red Solut'n.	1·40 Normal Iodine.	As.	As_2O_3.	As_2O_5.
1	30 c.c.	15·7 c.c.	0·0295 grm.	0·0390 grm.	0·0453 grm.
2	30	15·7	0·0295	0·0390	0·0453
3	30	15·7	0·0295	0·0390	0·0453
4	30	15·75	0·0296	0·0391	0·0454

Actually present :—

As = 0·0296 = 0·0390, As_2O_3 = 0·0453 As_2O_5.

Three estimations :—

No.	Red Solut'n.	1·40 Normal Iodine.	As.	As_2O_3.	As_2O_5.
1	60 c.c.	31·5 c.c.	0·0593 grm.	0·0783 grm.	0·0910 grm.
2	60	31·5	0·0593	0·0783	0·0910
3	60	31·6	0·0595	0·0785	0·0915

Actually present :—

As = 0·0593 grm. = 0·0782 grm. As_2O_3 = 0·0907 grm. As_2O_5

2.—100 c.c. H_2KAsO_4, 150 c.c. SO_2 solution, and 200 c.c. water were brought into a flask and reduced as above described. After boiling the liquid down to one-half the original volume, cooling and diluting to 1000 c.c., the following results were obtained. For each determination 100 c.c. solution were taken :—

No.	Red Solut'n.	1·40 Normal Iodine.	As.	As_2O_3.	As_2O_5.
1	100 c.c.	31·7 c.c.	0·0597 grm.	0·0788 grm.	0·0916 grm.
2	100	31·8	0·0599	0·0791	0·0918
3	100	31·7	0·0597	0·0788	0·0916
4	100	31·8	0·0599	0·0991	0·0918

Fifty c.c. of same solution required 15·9 c.c. $\frac{1}{10}$ normal iodine = 0·02995 As = 0·0395 As_2O_3 = 0·0459 As_2O_5.

The average number of c.c. of $\frac{1}{10}$ normal iodine used in this lot of tests is 31·75 ; the average number used in the lot immediately preceding is 31·53 ; the difference between the two is 0·22 c.c. This 0·22 is a distinct plus, and requires explanation in spite of the fact that owing to the extremely dilute iodine solution it is too small to occasion any decidedly appreciable error in the results. The excess is, I am inclined to believe, probably due to the action on the iodine of organic matter in the distilled water, the destructive capacity of this matter as regards iodine increasing, as a matter of course, with the increase in the quantity of water used, as well as with the length of time requisite for reducing and boiling down to the required volume. It will be observed that in the second experiment more water was used than in the first, and in consequence thereof that the time necessary for reducing and boiling down is greater in the latter than in the former case.

B. 1.—To test the method further I brought 2·475 grms. As_2O_3 into a litre-flask with a long narrow neck, added 100 c.c. pure nitric acid, and, having clamped the flask in an inclined position in the water-bath, heated the contents to boiling. As soon as all reaction had ceased the flask

* Fresenius, *Anleitung zur Qualit. Chem. Analyse*, 14 Aufl., cxcix., 9.
† Modern system. See Clemens Winkler's *Maasanalyse*, Freiberg, 1883.
‡ Alex. Muller, *Landw. Versuchs-Stationen*, xxvii., 340. See also

gently over a free flame until all hyponitric oxide fumes had disappeared and the solution was clear and colourless; 20 c.c. dilute sulphuric acid were then added, the solution was transferred to a porcelain dish, evaporated down until every trace of nitric acid was expelled, cooled, neutralised, and diluted to a litre: 50 c.c. of this solution were mixed with 150 c.c. SO_2 solution, 200 c.c. water added, and the whole was treated as already described—for two hours on the water-bath, two hours on the sand-bath, and finally boiled down over a free flame to a little less than one-half the original volume. The liquid after cooling was diluted to exactly 200 c.c., and for each of the following tests 50 c.c. taken:—

No.	Red Solut'n.	1-40 Normal Iodine.	As.	As_2O_3.	As_2O_5.
1	50 c.c.	12·5 c.c.	0·0235 grm.	0·0311 grm.	0·0361 grm.
2	50	12·5	0·0235	0·0311	0·0361
3	50	12·5	0·0235	0·0311	0·0361
4	50	12·5	0·0237	0·0313	0·0363

Since 1000 c.c. standard solution = 2·475 grms. As_2O_3, 50 c.c. = 0·12375 grm. As_2O_3; and since the 50 c.c. were after reduction and boiling down diluted to 200 c.c., 50 c.c. or ¼ of 200 c.c. = 0·0309 grm. As_2O_3, a figure which agrees very well with that found by analysis.

2.—100 c.c. standard solution, 200 c.c. SO_2 solution, and 200 c.c. water were reduced, boiled down, cooled, and diluted to 500 c.c. Four tests were made, each with 100 c.c.:—

No.	Red Solut'n.	1-40 Normal Iodine.	As.	As_2O_3.	As_2O_5.
1	100 c.c.	20·1 c.c.	0·0378 grm.	0·0499 grm.	0·058 grm.
2	100	20·1	0·0378	0·0499	0·058
3	100	20·05	0·0377	0·0498	0·058
4	100	20·1	0·0378	0·0499	0·058

Theory demands—

0·0375 As = 0·0495 As_2O_3 = 0·0575 As_2O_5.

Twenty c.c. of the standard solution should require, after reduction, 19·9 c.c. $\frac{1}{40}$ normal iodine, whereas, as will be seen, 20·1 c.c. were used. The cause of the error, 0·22 c.c., has already been suggested. The error is so small that it in no case materially affects the accuracy of the results.

Having had occasion during my examination of the Holthof method to subject several organic compounds, at high temperatures and under pressure, to the oxidising influence of certain reagents, the thought suggested itself that, perhaps, by acting on arsenic acid with sulphurous acid under pressure, the reduction of the former to the lower stage of oxidation might be easily accomplished, and that too in a comparatively short period of time. The results of some qualitative experiments in this direction will be found in the Chemical News, vol. li., No. 1320, March 13th, 1885. The results obtained were very satisfactory, and seemed to prove without a doubt that when arsenic acid, sulphurous acid, and water are heated for one hour in hermetically closed flasks, and at a temperature equal to that of boiling water, the arsenic acid is completely reduced to arsenious acid. In my article in the Chemical News I have given the results of seven experiments, the quantity of arsenic as arsenic acid in each test ranging from 0·06 to 0·90 grm. In every case excepting one the reduction was complete. In the last experiment (0·9 grm. arsenic acid present) 20 c.c. of the reduced solution gave with magnesia mixture, after boiling off the sulphur dioxide, a slight reaction for arsenic acid—one so slight, however, that upon filtering off the precipitate and dissolving it in a drop of nitric acid, no reddish brown colour or precipitate was obtained with silver nitrate and ammonia. In all the seven experiments my tests were made upon *portions* of the reduced solution; consequently it seemed well, before trying the process quantitatively, again to make a series of experiments, using the entire quantity of the reduced liquid for a test, exactly as was done in my examination of the Holthof method of reduction.

I proceeded as follows:—

The solution of H_2KAsO_4 was brought into a little bottle provided with a well-fitting ground-glass stopper, and capable of withstanding a pressure corresponding to the heat of a boiling water-bath, a strong solution of sulphurous acid run in, the bottle tightly stoppered, and the stopper firmly tied down with a piece of cord. The bottle was next placed in a water-bath, the contents of which had been brought to active boiling, and here permitted to remain for exactly one hour. After cooling, the reduced liquid was emptied into a flask, diluted to about 150 c.c., and boiled down to one-half the volume, care being taken to introduce into the flask a large platinum spiral. It was then transferred to a porcelain dish, evaporated to 50 c c., filtered, and tested for arsenic acid—(1) with silver nitrate, and (2) with magnesia mixture.* Six tests were made, but in no case could I, after boiling down, obtain in the 50 c.c. a definite reaction for arsenic acid.

I.

10 c.c. H_2KAsO_4 solution;
20 c.c. SO_2 solution.

10 c.c. = 0·0593 grm. As = 0·0782 grm. As_2O_3 = 0·090 grm. As_2O_5.

Reaction for As_2O_5 with silver nitrate, none.

II.

10 c.c. H_2KAsO_4 solution;
20 c.c. SO_2 solution.

10 c.c. = 0·0593 grm. As = 0·0772 grm. As_2O_3 = 0·090 grm. As_2O_5.

Reaction for As_2O_5 with magnesia mixture, none.

III.

20 c.c. H_2KAsO_4 solution;
30 c.c. SO_2 solution.

20 c.c. = 0·1186 grm. As = 0·1564 grm. As_2O_3 = 0·180 grm. As_2O_5.

Reaction for As_2O_5 with silver nitrate, none.

IV.

20 c.c. H_2KAsO_4 solution;
30 c.c. SO_2 solution.

20 c.c. = 0·1186 grm. As = 0·1564 grm. As_2O_3 = 0·180 grm. As_2O_5.

Reaction for As_2O_5 with magnesia mixture, none.

V.

30 c.c. H_2KAsO_4 solution;

30 c.c. = 0·1779 grm. As = 0·2346 grm. As_2O_3 = 0·270 grm. As_2O_5.

Reaction for As_2O_5 with magnesia mixture, none.

(To be continued.)

A METHOD OF FILTRATION BY MEANS OF EASILY SOLUBLE AND EASILY VOLATILE FILTERS.

By F. A. GOOCH.

The processes of analysis, in which it is desirable to redissolve precipitates from the filter after washing, or to separate a mixed precipitate into parts by the action of appropriate solvents, are many.

* The solutions stood 12 to 24 hours.

When a complete solution is the object, and the precipitate yields easily to solvents which do not affect paper injuriously, the use of the ordinary filter offers no difficulty. When, however, precipitates are to be treated with reagents which disintegrate paper-filters, the case is otherwise; and the attempt to remove, by solvents, any individual part of a mixed heterogeneous mass upon a filter is always an uncertain matter, As examples of cases of this sort, difficult to deal with, we may take the solution of acid sodic titanate in strong hydrochloric acid; or the purification of baric sulphate from included salts by digestion in strong hydrochloric acid; or the separation of sulphides which are soluble from those which are insoluble in alkaline sulphides; or the washing out of free sulphur from precipitated sulphides by means of carbon disulphide; or the separation of calcic and baric sulphates by the action of sodium hyposulphite. In cases of this nature it is often convenient to make use of the asbestos filter which I have previously described;* but this sometimes has its disadvantages. Thus, to recur to the examples just cited, acid sodium titanate may be filtered and washed upon an asbestos filter, and felt and precipitate treated together with hydrochloric acid, but it will be impossible to determine when solution is effected, because of the floating asbestos; and in separating the sulphides it would be necessary to know the weight of the asbestos felt, since it must be weighed finally with the insoluble sulphides, unless removed by a special treatment which involves the solution, filtration, and re-precipitation of the latter.

It is to meet cases like these that I have sought a filter which, in the reversal of the ordinary mode of separating filter and precipitate, should dissolve easily in solvents which do not affect the ordinary precipitates met with in analysis. The material which seems best suited to the case—light and fluffy, capable of making secure filters of any desirable degree of porosity, sufficiently insoluble in water and aqueous solution of salts, alkalies, and acids (excepting strong sulphuric, strong nitric, and glacial acetic acids), easily soluble in naphtha, benzol, carbon disulphide, ether, boiling alcohol, and essential oils, and not too costly—is anthracene.

The mode of preparing and using the filter is simple. Anthracene is slightly moistened with alcohol to make it miscible with water, diluted to the right consistency, and applied to the same apparatus, and in the same way as the emulsion of asbestos which is employed in making asbestos felts; that is to say, enough of the emulsion in water to form a layer of the proper thickness is poured into a perforated crucible, which is held tightly in a packing of rubber-tubing stretched over a funnel fitted in the usual manner to a vacuum-flask or receiver. After washing with water the filter is ready for use. If the felt happens to be too coarse for the use of the moment, it may be made as close as need be by coating the felt first deposited with a finer emulsion, made by dissolving anthracene in hot alcohol and precipitating with water. When voluminous precipitates are to be filtered, the large perforated cone, described in the former paper, to which I have referred, may be substituted with advantage for the crucible; or Cooke's improved form† of Carmichael's process of reverse filtration may prove most useful. In using the cone it is well to apply the anthracene in a thick layer.

To remove the anthracene filter from a precipitate it is only necessary to act with the proper solvent. It is usually convenient to stand the crucible containing precipitate and felt in a small beaker, add enough of the solvent, and gently warm until the anthracene dissolves. On the addition of water, or the reagent to work upon the precipitate, the solution of anthracene floats, and nothing remains to obstruct or obscure the action. If the precipitate dissolves entirely, the solution of anthracene may be separated from the aqueous solution by simply pouring the fluid upon a filter previously moistened with water, when the solution in water runs through, and the anthracene and its solvent remain and may be washed indefinitely with water.

If, on the other hand, the case is one of the division of precipitates, the anthracene and its solvent may be made to pass the filter, after the water has run through, by adding a little alcohol to overcome the repulsion between the solution and the water which fills the pores of the filter, the precipitate which stays behind being washed first with a solvent of anthracene, and then, if necessary, with alcohol followed by water; or, if the vacuum filter be used (either paper or asbestos, according to the circumstances of the case), both liquids leave the precipitate and traverse the filter together.

In general I prefer benzol as the solvent for anthracene, but some advantage may be gained in special cases by a proper choice of solvents. Thus, in removing intermixed sulphur from precipitated sulphides, both the anthracene and the sulphur may be dissolved in carbon disulphide in a single operation.

The ready volatility of anthracene, at a temperature very near its melting-point, 213° C., makes it easily separable in cases when to remove it by a solvent is not advisable. The treatment of a solution of anthracene, for example, with strong sulphuric or nitric acid is apt to produce carbonaceous or gummy residues. In such cases it is well either to heat precipitate and filter directly, or to first remove them from the crucible by means of a solvent for anthracene, then evaporate this, and raise the heat gently until the anthracene has vanished. The purification of precipitated baric sulphate, by dissolving it in hot, strong sulphuric acid, and re-precipitating by dilution, is a case in point, and one, too, in which the reversed filter may be used with great advantage. It may be remarked, in passing, that if one does not happen to possess a platinum rose, and does happen to have at disposal a perforated crucible, a very fair reversed filter may be improvised of the crucible, a piece of glass tubing, and a rubber stopper, the last being fitted to the crucible, and the tube passed through nearly to the perforated bottom.

At every point in the preparation and use of the anthracene filter I have found the manipulation peculiarly easy.—*American Chemical Journal.*

A NEW METHOD FOR THE DETERMINATION OF PHOSPHORUS IN IRON AND STEEL.*

By J. B. MACKINTOSH, School of Mines, New York.

(Concluded from p. 225.)

THESE two last experiments showed that oxygen was not sufficient to convert the phosphorus in the forms lost into phosphoric acid; so the problem resolved itself into finding a method of converting the lower oxygen compounds of phosphorus into phosphoric acid without simultaneously oxidising ferrous to ferric iron. The solution of this problem was obtained in the next trial. The process is the same as before described, using hydrochloric acid as the solvent, and a current of oxygen;† and after raising the solution to boiling, introducing an excess of a strong solution of sulphurous acid previously placed in the flask A, and continuing the boiling for some minutes. The result of the reaction is visible in the precipitation of sulphur in the solution, and the insoluble residue is much altered in appearance, being much more disintegrated. The results obtained in this experiment were: total phos.

* From the *Transactions of the American Institute of Mining Engineers.*

† The use of oxygen in place of hydrogen is recommended because it has no appreciable oxidising effect on the iron solution, while it prevents the reduction of the permanganate, which rapidly takes place with hydrogen.

9	Pig	0·880	HCl in O atmosphere boiled with excess SO_2, but all portions mixed.	—	—	—	0·865	0·015	Slight loss in course of analysis.			

phorus present, 0·882 per cent, weighed as magnesia pyrophosphate (care being taken to ensure its purity by re-solution and re-precipitation of the magnesia precipitate) distributed—

In residue	13·49 per cent.
In solution	80·84 ,,
In gas	5·67 ,,
	100·00 ,,
Loss	0·00 ,,

In confirmation of this result I made another determination in the same manner, starting at noon; by the following morning I found 0·865 per cent of phosphorus, and had lost a small amount in the course of the rather hurried analysis.

The results obtained are given above in tabular form.

I also made some confirmatory experiments on the sample used in experiment No. 5, weighing the yellow precipitate first obtained, instead of purifying it by re-precipitation. The precipitates carried traces of iron, which in experiments 11 and 12 entered into the magnesia precipitates. This explains discrepancies observable between the results calculated from the weights of the yellow precipitate and from those of the magnesic pyrophosphate.

Percentage P.	Old method. No. 5.	New Method. No. 10.	No. 11.	No. 12.
Weighed as yellow precipitate	1·447	1·49	1·451	1·463
No. of precipitations	2	1	1	1
Weighed as $Mg_2P_2O_7$	1·480	1·456	1·516	1·539
No. of precipitations	1	2	2	1

From inspection of this table it is seen that there is a far closer agreement between the results calculated from the weights of the yellow precipitate than in those calculated from the magnesic pyrophosphate; and I am of the opinion that the true percentage of this sample is very near 1·454, the average of the four lowest results obtained.

In experiment 10 the phosphorus found was distributed—

In residue	23·10
In solution	73·00
In gas	3·90
	100·00

In experiments 11 and 12 all portions were mixed together.

The following is a brief outline of the steps to be followed:—

1. Solution in hydrochloric acid in a stream of oxygen or air, absorbing the escaping gases in permanganate acidified with sulphuric acid.

2. Heating the solution to boiling, stopping the passage of the oxygen current, and carefully adding an excess of sulphurous acid solution, and continuing the boiling till the precipitated MnO_2 in the absorption-flask is redissolved. This boiling should last several minutes to ensure the completion of the reaction.

3. Disconnecting the junctions between the absorption-flasks and solution-flask, and between the solution-flask and the acid-flask, and allowing to cool.

4. Mixing solutions, filtering out residue which is placed (with filter-paper) in a porcelain casserole, oxidising with nitric acid and potassium chlorate, and evaporating to dryness.*

5. Boiling the solution till the excess of sulphurous acid is expelled, adding a few c.c. of permanganate to peroxidise a little of the iron, and precipitating basic acetates. Boiling the filtrate for other precipitates, to ensure getting all the phosphoric acid present.

6. Dissolving these precipitates in hydrochloric acid and adding to the solution of the residue in which, by this time, the paper will have been thoroughly destroyed.

7. Evaporating to dryness for silica, and proceeding as usual with the molybdate precipitation.

The saving of time by this process is the greater as the percentage to be determined is less. In a steel of low percentage, where it is necessary to use 10 grms. for the determination, necessitating the use of 120 c.c. of nitric acid for solution, by the old method, the time taken for the evaporation of this amount of liquid, for the subsequent thorough drying of the residue, and for the resolution and reduction of the iron to the ferrous state, is evidently much greater, and the operations followed are much more

* I prefer to filter out the residue instead of filtering it out with the first basic acetate precipitate, because it is difficult to work accurately on a muddy liquid, and because there is a probability of loss of phosphorus by the continued action of the hot acid solution on the residue, after the sulphurous acid has been expelled. By proceeding as directed this chance of loss is removed. Perhaps some of the loss in the ninth experiment may be due to this cause, as the residue in that ex-

tedious than by this method, where the phosphorus is concentrated at the start in but a few milligrms. of iron in very little bulk of solution, enabling the subsequent evaporation to dryness and thorough drying of the residue to be performed in a very short period.

In M. Tantin's experiments he used cast-iron only. Mine have been conducted on pig- and wrought-iron. It is possible that the difference in our results may be partially accounted for by different modes of occurrence of phosphorus similar to the different forms of carbon, but of this I cannot speak from experience, and merely offer it as a suggestion.

The small amount of phosphuretted hydrogen which is found seems to be the product of a secondary reaction between phosphorous acid and the nascent hydrogen evolved. Whether hypophosphorous or hypophosphoric acids are present, or, indeed, whether phosphorous acid is present, I am at present unable to say, but the results obtained point to the presence in the solution, along with phosphoric acid, of one or more of these, as the cause of loss. The use of sulphurous acid, however, oxidises these to phosphoric acid without affecting the iron, so that by this process a determination can be made in a day which formerly required several days.

In calculating the percentage of phosphorus from the weight of the yellow precipitate I have used in all cases the figure of 1·63 per cent phosphorus in the precipitate, and have thought it worth while to give the results I have obtained in two determinations I have recently finished. I prepared the yellow precipitate from phosphoric acid, precipitated in the usual manner with excess of molybdic acid. One of these precipitates (A) was purified from possible excess of molybdic acid by solution and re-precipitation; the other (B) was analysed without going through this process. The magnesia precipitate obtained from A was also purified by solution and re-precipitation, while that from B was ignited and weighed direct. The results are given below.

	A.	B.
Weight of yellow precipitate dried at 95° to 100° C.	1·2802	1·1428
Weight of $Mg_2P_2O_7$	0·0735	0·0664
Weight of P calculated from $Mg_2P_2O_7$	0·02053	0·01854
Percentage of P in yellow precipitate..	1·603	1·623
Weight of P calculated from yellow precipitate, assuming factor 1·63 per cent..	0·02087	0·01863

PROCEEDINGS OF SOCIETIES.

CHEMICAL SOCIETY.

Thursday, May 6th, 1886.

Dr. Hugo Müller, F.R.S., President, in the Chair.

The following were formally admitted Fellows of the Society:—Messrs. John W. King, William Herbert Hyatt, and George T. Holloway.

Certificates were read for the first time in favour of Messrs. James Blake, M.D., F.R.C.S., 1, Sussex Gardens, W.; Forbes Rickard, Ashcombe, Carlton Road, Putney; Charles A. R. Jowitt, Scotia Works, Sheffield.

The following papers were read:—

44. "*Paranitrobenzoylacetic Acid and some of its Derivatives.*" By Dr. W. H. Perkin, Jun., and Dr. E. Bellinot.

On account of the difficulty of producing ethylic benzoylacetate free from acetophenone, benzoic acid, and other impurities, unsatisfactory results were obtained on attempting to prepare the nitro-derivative directly from it; the authors have therefore prepared *paranitrobenzoylacetic acid*, $NO_2{\cdot}C_6H_4{\cdot}CO{\cdot}CH_2{\cdot}COOH$, from paranitrophenylpropiolic acid obtained by combining ethylic paranitrocinnamate with bromine and treating the resulting ethylic paranitrophenyldibromo propionate with alcoholic potash. The conversion of paranitrophenylpropiolic acid into paranitrobenzoylacetic acid is effected by dissolving the former (50 grms.) in 80 to 85 per cent sulphuric acid (2 to 3 kilos.), and maintaining the liquid at 35° to 40° for fifteen hours. The pure acid crystallises from benzene in microscopic needles; it melts at 135°, being resolved into paranitracetophenone and carbon dioxide, a decomposition which also takes place on boiling it with water. Owing to their instability, the preparation of its metallic salts is a matter of some difficulty. *Methylic paranitrobenzoylacetate* crystallises from alcohol in monoclinic prisms, melting at 106° to 107°; on treatment with sodium methylate or ethylate, it yields a monosodium derivative of remarkable stability. On heating this compound with benzyl chloride and a little alcohol in sealed tubes at 150°, it is converted into *methylic paranitrobenzoylbenzylacetate*, a body which crystallises from dilute alcohol in colourless plates, melting at 57°. *Ethylic paranitrobenzoylacetate* crystallises from a mixture of benzene and light petroleum in monoclinic prisms—of which, as well as of the methylic salt, measurements by Prof. Haushofer are given in the paper—melting at 75°; it dissolves fairly easily in sodic hydrate solution, being re-precipitated unchanged on the addition of acids. The sodium derivative may be obtained in a pure state by means of sodium ethylate: it crystallises from boiling alcohol in small orange-yellow needles, and may even be re-crystallised from water; from it other metallic derivatives may readily be prepared.

Ethylic paranitrobenzoylethacetate, prepared by the action of ethyl iodide on the sodacetate, crystallises from dilute alcohol in colourless plates, melting at 39° to 40°; the corresponding *allylacetate*, prepared by the action of allyl iodide, melts at 45° to 46°. All attempts to prepare the acids from these salts by hydrolysis were unsuccessful.

Ethylic diparanitrobenzoylsuccinate,—

$$(C_6H_4{\cdot}NO_2)_2C_2H_2{\cdot}(COOEt)_2,$$

obtained by treating ethylic paranitrobenzoylsodacetate with iodine, crystallises from dilute alcohol in colourless needles melting at 180°. By the action of nitrous gas on an ethereal solution of ethylic paranitrobenzoylacetate, the *isonitroso*-derivative is obtained; it crystallises from dilute alcohol in colourless needles melting at 220°.

45. "*An Acetic Ferment which forms Cellulose.*" By Adrian J. Brown.

The acetic ferment described in this paper is well known as the "vinegar plant" or "mother." Pure cultivations of it were made by a combination of the "fractional" and "dilution" methods, and also by growing it in a solid gelatin medium. The mode of growth of the tough gelatinous membrane of the ferment is described, its general appearance being very similar to a soft animal membrane. The membranous growth of the "vinegar plant" is the only form which it assumes, no matter how the conditions are varied. *Bacterium aceti* never assumes this form; moreover the "vinegar plant" gives all the chemical reactions of cellulose, but are not yielded by any form of *B. aceti*: the two ferments are therefore specifically distinct. The morphology of the ferment is described, and also its fermentive actions. The latter, so far as examined, are similar to those of *B. aceti* (comp. *Trans.*, 1886, 172), viz., ethylic alcohol is oxidised to acetic acid, and the acid so formed is afterwards decomposed. Dextrose yields gluconic acid, and mannitol is converted into lævulose. Like *B. aceti* also, it had no fermentive action on cane-sugar or lævulose.

Treatment of a membrane of the "vinegar plant" by H. Müller's bromine method leaves a film of pure cellulose of the same shape and character as the original membrane. The reactions of this cellulose are given, showing it to be ordinary cellulose like that from cotton-wool.

The formation and use of cellulose by a simple cell plant is of interest in connection with the important part this body plays in the more highly organised plants. Experiments were therefore made to determine from what bodies the "vinegar plant" forms its cellulose. Cane-sugar, starch, and ethylic alcohol are not converted into this body; dextrose, however, can be so converted. In this latter case, therefore, the cells of the ferment have a double action upon the sugar, viz., the production of gluconic acid and the building up of cellulose. The latter action, however, cannot be considered one of fermentation.

Mannitol and lævulose are converted into cellulose, and favour the growth of the ferment more strongly than dextrose.

The usual method of preparing "home made" vinegar by means of the "vinegar plant," is to introduce a membrane into a solution of cane-sugar. The pure ferment has no action on this sugar, but the ordinary impure ferment used contains yeast cells, and these invert and ferment the sugar, so preparing alcohol for conversion into vinegar by the acetic ferment.

The name *Bacterium xylinum* is suggested for the "vinegar plant."

Discussion.

Mr. Warington after noticing the remarkable formation of cellulose from lævulose, said that it would be important to ascertain, if possible, at what stage oxidation sets in. Recent experiments by Müntz clearly show that organisms may promote oxidations which cannot be of service to the life of the organism, and which, therefore, must be regarded as unessential thereto.

The President said that it had hitherto been always supposed that cellulose was the very foundation of all vegetable cells, and it was therefore particularly interesting to have it established that certain bacteria did not contain cellulose.

At the next meeting, on May 20th, there will be a ballot for the election of Fellows, and the following papers will be read:—

"The Action of Aldehydes and Ammonia on Benzil" (continued). By Francis R. Japp, F.R.S., and W. Palmer Wynne, B.Sc.

"Imabenzil." By the same.

"Ammonia-derivatives of Benzoïn." By F. R. Japp and W. H. Wilson, Ph.D.

"Compounds of Benzil and Benzoïn with Alcohols." By F. R. Japp and Julius Raschen.

"The Action of Phosphoric Sulphide on Benzophenone." By the same.

"The Preparation and Saponification of Hydrocyanides of the Diketones." By F. R. Japp and N. H. J. Miller, Ph.D.

PHYSICAL SOCIETY.

May 8th, 1886.

Prof. H. McLeod, F.R.S., Vice-President, in the Chair.

Mr. W. A. Price was elected a Member of the Society.

The following communications were read:—

"*On a Modified Form of Wheatstone's Rheostat.*" By Shelford Bidwell.

A wire is coiled upon a non-conducting cylinder, as in the ordinary forms of rheostat, one end of the wire being in contact with the brass axle of the cylinder. A screw is cut upon the axle, the pitch being equal to the distance between the consecutive turns of the wire, and this, working in a fixed nut, causes the whole cylinder to travel in the direction of its axis. A fixed spring bears upon the wire at a convenient point, and by the travelling motion of the cylinder this point of contact remains fixed in space, and the effect of turning the cylinder is to introduce more or less resistance between the spring and the brass axle. Binding screws on the base of the instrument are in contact with the nut and the bearing spring. Though this arrangement has several obvious advantages over the usual forms, Mr. Bidwell does not recommend it in cases where it is required to introduce a known resistance, but where it is important to adjust a resistance to a nicety or to cause a continuous variation it is of great use.

Prof. Perry, remarking upon the importance of being able to vary a resistance gradually, described an instrument he had used with advantage. A number of plates of gas-carbon are placed between two parallel copper plates, one of which is fixed and the other adjustable by a screw: by applying pressure by means of the screw the resistance between the plates can be varied uniformly and regularly from 2 to 10 ohms, beyond which point the increase is very rapid.

"*On a Theorem relating to Curved Diffraction Gratings.*' By Walter Baily.

In a paper read before the Society in January, 1883, the author showed that if a plane be taken perpendicular to the lines of a curved diffraction grating and a normal to the grating be taken as the initial line, then the equation—

$$\frac{\mathrm{Cos}^2\,\theta}{r} = \frac{\mathrm{Cos}\,\theta}{c} + \frac{1}{d},$$

in which c is the radius of curvature of the grating and d is an arbitrrary constant, gives a curve having the property that if a point of light be placed anywhere upon it, the curve is the locus of the foci of all diffracted rays, whether reflected or transmitted. In the present investigation d is supposed to be greater than c, which allows of the source of light being at infinity. The points where the curve given by the above equation cuts the normal are called the normal foci. There are two of these, one relating to the reflected and the other to the transmitted light, the grating being supposed to consist of a number of opaque lines in space. It is then shown that if the grating be supposed to turn about the line in it intersecting the initial line, the normal foci will trace out two parabolas whose common focus is the origin, and common *latus rectum* is equal to the diameter of curvature of the grating, the parabola for reflected light being convex to the source of light, and that for transmitted light concave.

"*On some Thermo-dynamical Relations.*" Part IV. By Prof. W. Ramsay and Dr. Sydney Young.

The first part of this communication deals with Profs. Ayrton and Perry's criticisms upon the previous papers by the authors upon this subject. In the second part a brief review is given of the various attempts that have been made to represent the pressure of a saturated vapour as a function of the temperature.

Molecular Weight of Liquid Water.—Thomsen has called attention to the fact that the conclusion reached by Raoult in his researches on the freezing-point of saline solutions, that water possesses, in the condition of liquid, twice the molecular weight which it has in the condition of vapour, coincides with the conclusion to which he himself had come from his investigations on the constitution of hydrated salts. In his thermo-chemical researches Thomsen says: "A glance at the table of heat of hydration of hydrated salts shows that the water molecules enter often in pairs with the same heat-change; a fact explicable either by supposing that the molecules of water are symmetrically placed in the molecule of the salt, or, and perhaps more probably, that the molecular weight of liquid water is twice that of water vapour. The similarity of these conclusions, from widely different fields of investigation, is noteworthy.—*Ber. Berl. Chem. Ges.*

NOTICES OF BOOKS.

A Pocket-Book for Chemists, Chemical Manufacturers, Metallurgists, Dyers, Distillers, Brewers, Sugar Refiners, Photographers, Students, &c. By THOMAS BAYLEY, Analytical and Consulting Chemist and Assayer. Fourth Edition. London and New York: E. and F. N. Spon.

WE have here the issue of this useful laboratory-companion for the present year. The work treats in succession of atomic weights and factors, useful data, chemical calculations, rules for indirect analysis, weights and measures, thermometers and barometers, chemical physics, boiling-points, solubilities, specific gravities, instructions for analysis, mineralogy, assaying, alcohol, beer, sugar, and miscellaneous technical matter. There is also an appendix.

We find two tables of atomic weights, the second of which gives the latest determinations. In the first table gold and platinum rank both = 196·7. In the second gold is given = 196·2, whilst platinum retains the figure 196·7. But in the most recent determinations with which we are acquainted, *i.e.* those of Seubert, verified by Halberstadt, Pt = 194·576, a result more in conformity with what theory requires.

In the paragraph on alkalimetric indicators we find mention only of litmus, cochineal, and turmeric. This seems an oversight, since certain indicators which have recently come into use are preferable under a variety of circumstances.

Perhaps doubts may be raised concerning the fairness of the distribution of space. Alcohol, beer, and sugar—the last a moribund, if not a dead industry as far as Britain is concerned—these three subjects occupy 71 pages, whilst to all other departments of technical chemistry only 20 pages are allotted.

The tables for the use of that fallacious instrument, Quevenne's lacto-densimeter, might have safely been omitted.

The table showing the periodic classification of the elements bears a very judicious and equitable heading. It is entitled: "The elements arranged by Mendelejeff according to Newland's periodic classification."

As a whole this pocket-book must, as in former years, continue to be regarded as an invaluable vade mecum both for the laboratory and in chemical works.

CORRESPONDENCE.

PATENTS FOR ANALYTICAL PROCESSES.

To the Editor of the Chemical News.

SIR,—In thanking you for your recent notice of three of my small Manuals I hope you will allow me to make brief statements relating to an Appendix and to the question of Patents—both of which subjects were mentioned in your notice.

My Manuals appeal to a wide public; the "Water Analysis," for instance, has had nearly 7000 readers since it first appeared in the year 1868. Not only is the audience wide, but it is select, being, to a great extent, a student audience. Under these circumstances I am quite alive to the responsibilities laid upon me.

The Appendix of the "Water Analysis" is designed to place before the student the history of the development of modern water-analysis, and accordingly in the Appendix I have reproduced some of the original papers in the form in which they were communicated to scientific journals, and a short account of the violent controversies which have raged round the ammonia-process.

With respect to the patenting of the moist combustion process by Mr. Cooper and myself, your remark that "Until 1893 the process is protected against practical criticism, and possibly against general adoption," embodies a strange variety of errors. It omits to take into account the little detail that, as a matter of fact, the patentees have not chosen to avail themselves of all their privileges, and have not prolonged the patent beyond the first seven years. That, however, is a very trifling detail compared with the insinuation that, because the Crown had granted to Mr. Cooper and to me a monopoly of our moist combustion, therefore the public would be deprived of the benefits arising from the working of the process.

Surely we have a right to ask, Where does your reviewer place the fault? Does he mean that we are so greedy that we will not grant licenses on fair terms? Or does he mean that contemporary chemists will only work processes when they are able to defraud the inventors of the remuneration which is due to them?—I am, &c.

J. ALFRED WANKLYN.

May 1, 1886.

[Most chemists who compare our notice of Mr. Wanklyn's works (CHEMICAL NEWS, vol. liii., p. 213) with the above letter will feel some surprise. As regards the "moist combustion process" we make no "insinuation," but we openly condemn, on principle, the step—unprecedented as we believe—of patenting an analytical process. Whether licenses under the Patent were readily obtainable or not, and on what terms they were granted, are, from our point of view, utterly irrelevant questions. We are glad to learn that the Patent has been suffered to lapse, and trust that it may now have a fair trial. So far many chemists have ignored it, not from any wish to "defraud the inventors," but by way of protest against the unusual step which the latter have taken.—ED. C. N.]

The Ptomaines and the Leucomaines.—Armand Gautier.—The first portion of a summary of a paper read by M. Gautier before the Academy of Medicine.

Effects of Zinc Sulphate upon the Organism.—M. Lepetit.—A poisoning case: a "sister" in charge of the pharmacy of the hospital department of a penitentiary administered to a patient by mistake 60 grms. zinc sulphate in place of sodium sulphate, which had been ordered by the visiting physician. After death the zinc was found to have been absorbed into the system. In mentioning that the "sister" was sentenced to a fine of a few francs, the writer asks what punishment would have been awarded to a pharmacist who had made so fatal a mistake?

On Potable Waters.—M. Lajoux.—The author determines the organic matter by the permanganate process; the albumenoid ammonia and ammonia by the method of Wanklyn and Chapman, and the nitric acid by the process of Grandval and Lajoux. He also examines microscopically and determines free oxygen by Gerardin's method.

The Composition of Wine-Brandies.—Ch. Ordonneau.—Alcohol distilled from wine contains normal butylic alcohol; in the spirit distilled from maize, beet-root, or potatoes there is found instead isobutylic alcohol, without a trace of normal butylic alcohol.

Experiments on Fatty Matters.—Ch. Dubois and L. Padé.—The authors have determined the solidification- and melting-points of the butter of various samples of cocoa, the solidification of the fatty acids, their proportion in the butter, and their solubilities in absolute alcohol at different temperatures.

Researches on Combustion.—Albin Figuier.—The author demonstrates that nitric and nitrous acids are formed during the combustion of olive oil, ethylic alcohol, and coal-gas. Pure hydrogen burning against a smoked wire gauze yielded hydrocyanic acid, but no nitrous or nitric acid.

Assay of Commercial Pepsines.—Everett Coombs.—From the *Pharmacist*.

Filtration of Potable Waters in the Household.—C. Méhu.—Descriptions and figures of some of the most popular filters, both of English and French makes.

Fehling's Liquor as a Reagent in the Clinical Analysis of Urine.—L. Jolly.—Fehling's liquor, according to the proportions used, may indicate the presence of peptones, of uric acid in excess, of phosphoric acid in excess in urines respectively poor or rich in uric acid, and of glucose. If 1 c.c. of Fehling's liquor is mixed with 8 to 10 c.c. of urine, shaken up, and boiled, the liquid may remain blue, which signifies nothing. But if it is decolourised with a pale yellow flocculent precipitate floating in the liquid, peptone is present. If the liquid turns orange and there is an orange precipitate, we have glucose. If equal parts of Fehling's liquor and urine are mixed in a test-tube and boiled and the clear liquid remains blue there is little uric acid, If it becomes green the urine contains an excess of uric acid or of a urate. If the precipitate is scanty there is little phosphoric acid, but if copious phosphoric acid is present in excess.

Die Chemische Industrie.
Vol. ix., No. 2, February, 1886.

Action of certain Acids, Alkalies, and Saline Solutions upon some of the Metals most employed in the Arts.—G. Lunge.—We have here an examination of the action of ordinary sulphuric acid upon cast-irons. The conclusion reached is that at ordinary temperatures and with exclusion of air the action of sulphuric acid, pure or commercial, at strengths of 66° to 50° B., is very insignificant, and noteworthy differences as regards the various qualities of iron could not be distinguished. At the boiling-point of water the action is much greater, that of acid at 66° B. being the slightest, that of acid at 60° B. 1½ times greater, and that of acid at 50° B. 3 times greater. The differences at tne boiling-points of the acids are much more decided. Acid of 66° B. has little more action at its boiling-point (295°) than at 100°; acid of 60° B. acts at its boiling-point (200°) on the average 14 times stronger than at 100°, and 20 times stronger than the 66° acid at 295°. The 50° B. acid, which at 100° acts twice as strongly as that of 60° B., acts at its boiling-point (147°) less strongly than that of 60° at 200°. In the second chapter the author examines the action of monohydrated sulphuric acid upon cast-iron, wrought-iron, copper, and lead. At common temperatures and at 100° there is very little action either upon cast- or wrought-iron if air is excluded. Copper and lead are strongly attacked at common temperatures, lead more than copper. At 100° lead is scarcely more affected than at 20°, whilst copper enters into violent reaction with escape of sulphurous acid. The third chapter gives an account of the action of saturated solutions of sodium chloride and ammonium chloride upon the same metals. With sodium chloride the attack is slight in all cases, but quite perceptible, especially on cast-iron, and at higher temperatures on lead. The action of ammonium chloride is much stronger. Contrary to the common opinion lead is much more attacked in the cold by a strong solution of sal-ammoniac than iron. At a boiling heat it resists rather better than iron but far worse than copper. Lastly, we find an account of the action of caustic soda-lye, sodium sulphide, and sulphate upon the same metals. Caustic soda has little action upon iron at 15° and 100°, but more upon wrought-iron than cast-iron. Upon copper the action is more considerable, and upon lead still more so if the lye is dilute. Sodium sulphide, even in dilute solution, has a much stronger action upon iron and copper. Upon lead the action is slight, even at 100°. Sodium sulphate has little effect upon copper and lead, but its action upon iron is considerable.

Revue Universelle des Mines, de la Metallurgie, &c.,
Vol. xix., No. 1, January and February, 1886.

Electrolysis in Metallurgy.—V. Zoppetti.—The author gives here a summary of the various electro-metallurgical procedures, and especially of the electrolytic method employed at the Casarza copper-works. The secondary products are sulphuric acid, iron sulphate, and silver.

MEETINGS FOR THE WEEK.

Monday, 17th.—Society of Arts, 8. (Cantor Lectures). "Animal Mechanics," by Dr. B. W. Richardson, F.R.S.
Tuesday, 18th.—Institution of Civil Engineers, 8.
—— Pathological, 8.30.
—— Royal Institution, 3. "The Function of Circulation," by Prof. Arthur Gamgee, F.R.S.
—— Society of Arts, 8. "Japanese Art Work," by Ernest Hart.
Wednesday, 19th.—Society of Arts, 8. "Watchmaking by Machinery," by Prof. Leonard Waldo.
—— Meteorological, 7.
—— Pharmaceutical, 11. (Anniversary).
Thursday, 20th.—Royal, 4.30.
—— Royal Society Club, 6.30.
—— Royal Institution, 3. "The Alkaloids," by Prof. Dewar, F.R.S.
—— Chemical, 8. Ballot for the Election of Fellows.
Friday, 21st.—Royal Institution, 9. "The Forms of Seedlings: the Causes to which they are Due," by Sir John Lubbock, F.R.S.
—— Society of Arts, 8. "Everyday Life of Indian Women," by Capt. R. C. Temple.
Saturday, 22nd.—Royal Institution, 3. "How to Form a Judgment on Musical Works," by Prof. Ernst Pauer.
—— Society of Arts, 3. "Electricity," by Professor George Forbes.
—— Physical, 3.

NOTES AND QUERIES.

*** Our Notes and Queries column was opened for the purpose of giving and obtaining information likely to be of use to our readers generally. We cannot undertake to let this column be the means of transmitting merely private information, or such trade notices as should legitimately come in the advertising columns.

Amalgamation.—Can any correspondent tell me whether any other compound has been substituted for sodium amalgam in quartz and pyrites amalgamation for gold, and how I should obtain and use it.—J. D. A. S.

ELECTROLYTIC CONDUCTION IN RELATION TO MOLECULAR COMPOSITION, VALENCY, AND THE NATURE OF CHEMICAL CHANGE:

BEING AN ATTEMPT TO APPLY A THEORY OF "RESIDUAL AFFINITY."*

By HENRY E. ARMSTRONG Ph.D., F.R.S.

(Continued from p. 231).

Composite Electrolytes (continued).

THE evidence afforded by the oxy-acids derived from the halogens appears to me to be equally striking. The following are Ostwald's numbers, including those for nitric acid.

TABLE II.

v.	Nitric acid.	Chloric acid.	Perchloric acid.	Bromic acid.	Iodic acid.	Periodic acid.
2	77·9	77·9	79·1	—	42·57	
4	80·4	80·2	82·2	—	50·56	23·71
8	82·8	82·3	84·6	—	59·00	30·59
16	84·9	84·0	86·2	—	66·3	39·49
32	86·3	85·3	88·1	79·4	72·3	49·23
64	87·4	86·4	89·2	81·7	76·9	59·48
128	88·2	87·9	89·7	84·1	80·2	69·06
256	88·4	88·7	89·9	86·1	81·8	76·70
512	88·8	88·7	89·8	87·4	83·0	82·59
1024	88·9	88·6	89·8	88·4	83·1	85·38
2048	88·2	87·3	89·3	89·0	82·9	87·95
4096	86·6	85·7	87·8	88·8	81·8	86·62

It will be observed that nitric, chloric, and perchloric acids differ but little; that bromic acid has a considerably lower initial conductivity, and does not attain the maximum so soon; that iodic acid differs still more; and that the behaviour of periodic acid is altogether peculiar—being that of a polybasic acid, it may be added. Ostwald regards it as most surprising—"*in hohem Grade befremdlich*"—that periodic acid should be much weaker than iodic acid, and that the latter should be considerably inferior to iodhydric acid. To my mind their behaviour is absolutely what might be expected of these acids. Although the molecules in liquid nitric, chloric, and perchloric acids are probably not of the simple composition represented by the formulæ HNO_3, $HClO_3$, and $HClO_4$ respectively, the chemical behaviour of these acids does not indicate any great difference between them; owing, however, to the accumulation of oxygen atoms, perchloric acid may be expected to exercise a somewhat greater influence than chloric acid, as it actually does. Chemists are agreed that bromine has less affinity for oxygen than chlorine; hence it may be inferred that the oxygen in bromic acid would have greater residual affinity than the oxygen in chloric acid, and that, therefore, bromic acid would form complex aggregates more readily than chloric acid, and consequently have less influence in electrolysis than chloric acid. This is true in a much greater degree of iodic, and still more of periodic acid;† it is well known that the former not only yields salts of the type $M'IO_3$, but also acid salts such as KHI_2O_6; and that periodic acid forms a series of very complex salts.

The acids of phosphorus form another interesting series:—

TABLE III.

v.	H_3PO_2.	H_3PO_3.	H_3PO_4.
2	30·89	28·63	14·22
4	37·91	34·29	17·00
8	45·81	41·14	21·26
16	54·13	49·09	27·09
32	62·10	56·96	34·41
64	69·06	64·52	43·05
128	74·05	70·21	53·11
256	77·84	74·54	61·8
512	79·92	77·57	69·9
1024	81·00	79·11	75·4
2048	81·39	79·75	79·0
4096	80·48	79·07	79·8

These numbers afford to my mind the clearest possible evidence that we are dealing with complex molecules. It is especially noteworthy that the maximum never exceeds that of the monobasic acids,* even in the case of phosphoric acid, which is universally regarded as a tribasic acid, and that the *monobasic* hypophosphorus acid is the strongest and the *tribasic* phosphoric acid is the weakest. In very dilute solution phosphoric acid has less influence than even acetic acid, according to Kohlrausch.

It may be well also to quote Ostwald's numbers for sulphurous, selenious, sulphuric, and selenic acids.

TABLE IV.

v.	Sulphurous acid.	Selenious acid.	Sulphuric acid.	Selenic acid.
2	—	7·63	92 7	97·3
4	19·19	9·73	96·4	103·2
8	25·43	12·70	100·6	109·9
16	32·79	16·60	107·4	117·7
32	41·60	21·73	116·3	127·0
64	50·1	28·24	127·3	138·3
128	58·9	36·15	139·2	148·7
256	66·5	45·11	150·6	157·9
512	72·5	54·27	160·9	164·4
1024	77·1	62·79	169·1	169·7
2048	80·4	69·40	174·4	173·4
4096	83·6	73·58	177·1	174·4
8192	—	—	176 9	173·4

It will be observed that sulphuric and selenic acids are nearly alike in behaviour, the latter being somewhat more active in concentrated solutions; it is noteworthy that of all the polybasic acids studied by Ostwald, these are the only two containing a *single* negative radicle (SO_4,SeO_4) which exhibit a conductivity in excess of that which characterises the monobasic acids.†

The numbers obtained for sulphurous and selenious acids are deserving of study. Sulphur dioxide is far from being a perfect gas under ordinary conditions; in the liquid state it is probably rich in aggregates of SO_2 molecules, and these may be to a large extent conserved in concentrated aqueous solutions. But the main explanation of the variation in conductivity on dilution must be looked for, I think, in the peculiar relation which sulphur dioxide manifests to water; it is more than probable that the initial interaction involves the formation of a *hydrate* $(SO_2)x(OH_2)y$, and that from this on dilution is formed

* A Paper read before the Royal Society, March 25th, 1886.

† The existence of a stable oxide of the formula I_2O_5, as well as thermo-chemical data, have been interpreted as evidence that iodine has a greater affinity for oxygen than even chlorine. I am inclined to take the contrary view, however, and to regard the stability of the oxide I_2O_5 as due less to the high affinity of iodine for oxygen than to its low affinity for itself and the high affinity of oxygen for oxygen.

* Ostwald appears to be of the opinion that if the dilution could be carried far enough, a maximum conductivity = *n*·90 would eventually be attained in the case of every *n*-basic acid. It appears to me that neither do his numbers warrant this—and those here under discussion are an especially good illustration—nor is it likely to be the case on my hypothesis.

† Ostwald infers from the great increase in molecular conductivity that the manner in which the acid is electrolysed varies with the strength of the solution; he supposes that in more concentrated solutions sulphuric acid is resolved into H and HSO_4, and that both atoms of hydrogen are split off only as the solution becomes more diluted. This appears to me to be altogether improbable.

sulphurous acid, $SO(OH)_2$, and perhaps also "sulphonic acid," $H.SO_3H$. Taking into account the properties of selenious oxide, Ostwald's results appear to me in this case again to lead to but the one conclusion, that conductivity increases in consequence of the specific influence of the fundamental molecule of the compound making itself more and more felt, as by dilution it becomes more and more disentangled from its fellows.

The behaviour of solutions of neutral metallic salts on dilution is very similar to that of acids; abundant proof of this is afforded, especially by F. Kohlrausch's refined measurements, of which an account has recently been published (*Wied. Ann.*, 1886, xxvi., 162). I venture to think that a similar explanation to that above given for oxides will apply to salts; and also that the low molecular conductivities of salts as compared with corresponding acids may be regarded as confirmatory of my hypothesis. I think we must admit that the metals generally have less affinity than hydrogen for negative radicles; if this be granted we have at once an explanation of the fact that metallic salts are mostly fixed solids, few of which are more than moderately soluble in water, while many are very difficultly soluble and insoluble, whereas the corresponding acids are mostly volatile and readily soluble in water, if not miscible with it in all proportions. The affinity of the negative radicles being less exhausted by union with metals than with hydrogen, the fundamental molecules of salts are more prone to unite together to form complex aggregates.

Arrhenius, who has studied the electrical behaviour of solutions of a number of salts,* attributes the change observed in molecular conductivity on dilution—as I have done—to molecular changes; but his deductions are all based on the acceptance of the Williamson-Clausius hypothesis of dissociation.

My hypothesis would also account for the increase in conductivity in composite electrolytes with rise of temperature. It is true that as temperature rises the influence which individual molecules exert upon each other would be lessened; but, on the other hand, the complex aggregates would become more and more completely resolved into their fundamental molecules, the velocity of molecular motion would increase, and the tendency of the constituent atoms to remain united would be lessened. From this point of view the determination of the coefficient of change of conductivity with temperature in the case of substances whose molecular conductivity increases considerably on dilution in comparison with allied compounds which exhibit only a slight variation in molecular conductivity on dilution affords an interesting subject for investigation. F. Kohlrausch has already pointed out (*Pogg. Ann.*, 1875, cliv., 236) that in the case of all neutral salts, "der Einfluss der Temperatur auf das Leitungsvermögen mit wachsender Verdünnung sich Anfangswerthen nähert, die zwischen engen Gränzen liegen," and the experiments of F. Kohlrausch and Nippoldt on solutions of sulphuric acids (*Ibid.*, 1869, cxxxviii., 286) show that the resistance diminishes to a much greater extent for equal increments of temperature in concentrated than in dilute solutions. (See Table V.)

As concentrated solutions would be richer in complex aggregates than dilute solutions, these results are in entire accordance with my hypothesis: it does not appear to me that they can be satisfactorily interpreted in terms of the dissociation hypothesis.

In cases where the influence of the one member of the composite electrolyte upon the other is but slight, it may happen that the effect of temperature in diminishing this influence will outweigh that due to molecular simplification, and that, in consequence, conductivity will diminish with rise of temperature; a mixture of alcohol and ether would appear to furnish an example of this kind: according to Pfeiffer's recent observations (*Wied. Ann.*, 1885, xxvi., 226), such a mixture behaves as a metallic conductor of very high resistance.

TABLE V.

Percentage of sulphuric acid.	Resistance (Mercury=1).	Percentage increment of conductivity for 1° C.
0·2	465,100	0·47
8·3	34,530	0·653
14·2	18,946	0·646
20·2	14,990	0·799
28·0	13,133	1·317
35·2	13,132	1·259
41·5	14,286	1·410
46·0	15,762	1·674
50·4	17,726	1·582
55·2	20,796	1·417
60·3	25,574	1·794

The increase in conductivity of graphite and gas-retort carbon on heating, and the effect of light on the conductivity of (? impure) selenium and some other substances (Shelford Bidwell, *Phys. Soc. Proc.*, 7, cxxix., 256), appear to me to be also explicable on the assumption that in all these cases we are dealing with composite electrolytes.

If any further proof be needed of an intimate connection between molecular composition and electrolytic conduction it is most conclusively afforded, I think, by the observations of W. Kohlrausch on chloride, bromide, and iodide of silver (*Wied. Ann.*, 1882, xvii., 642), which are exhibited in the curves accompanying this paper. In the fused state these compounds are better conductors than the most highly conducting mixture of sulphuric acid and water, which of all liquids is the best conductor at ordinary temperatures. On reference to the curves it will be seen that the resistance of both silver chloride and bromide suddenly increases when the change from the fused to the solid state sets in; but that no such change takes place in the case of the iodide. Silver iodide fuses at 527° according to Rodwell, but at about 540° according to Kohlrausch; its electrical resistance increases only gradually after it has become solid, and remains almost a linear function of the temperature during an interval of 400°, until suddenly at near 150° it increases enormously, this change taking place at the moment when, according to Rodwell (*Phil. Trans.*, 1882, 1133), it passes from the transparent plastic amorphous solid to the opaque brittle crystalline state, the volume increasing considerably as shown by the curve. Kohlrausch has proved most conclusively that the solid iodide may undergo electrolysis. It would seem that almost immediately after solidification in the case of silver chloride and bromide, practically the whole mass consists of complex aggregates so constituted as to be exceedingly bad conductors, but that such aggregates are formed much less readily by silver iodide.

Metallic Conduction.

I do not propose in any way to discuss metallic conduction, but merely to call attention to some of the analogies between it and electrolytic conduction.

It is conceivable, and it would appear probable from the fairly regular manner in which the electrical resistance of most pure metals decreases as the temperature falls, the coefficients of change being practically very nearly the same in all cases, that the increase in resistance as temperature rises is mainly due to the increase in molecular inter-distances. As a rule, resistance increases on the passage of a metal from the solid to the liquid state, but there are noteworthy exceptions, from which it would

* *Bihang till Kongl. Svenska Vetenskaps-Akademiens Handlingar.* Attonde Bandet. Häfte 2. Stockholm, 1884. Arrhenius, S.: "Recherches sur la Conductibilité Galvanique des Electrolytes. I. La Conductibilité Galvaniqne des Solutions Aqueuses extrémement diluées, determinée au moyen des Depolarisateurs." 63 pp. II. "Théorie Chimique des Electrolytes." 89 pp. Although aware of his work from Ostwald's reference to it, I was unable to study his memoir until after this paper had been elaborated. Ostwald's quotations, moreover, did not enable me to realise the importance which Arrhenius attaches to the occurrence of molecular simplification and changes in composition on dilution.

appear probable that even in pure metals conductivity to some extent depends on molecular composition; thus the conductivity of bismuth increases at the moment of fusion from 0·43 to 0·73 of that of mercury at 21°, and that of antimony from 0·59 to 0·84 (L. de la Rive, *Comp. Rend.*, 1863, lvii., 691); it is well known that bismuth contracts considerably on fusion, and this is probably also the case with antimony. Again, according to Bouty and Cailletet (*Ibid.*, 1885, c., 1188), the resistance of mercury decreases at the point of solidification in the ratio 4·08 : 1; this is a remarkable increase in conductivity, and it is difficult to believe that it is wholly due to mere contraction of volume.

That the behaviour of alloys is worthy of far more attention than it has hitherto received appears most clearly from the few data at disposal. As being the most instructive instance, I append the curve given by Professor Lodge, representing the specific conductivities of the copper-tin alloys (*Phys. Soc. Proc.*, 1879-80, iii., 158). He examined five alloys, containing respectively 80·8, 38·2, 31·7, 12·6, and 9·7 per cent by weight of tin, which were prepared by Professor Chandler Roberts; the dotted curve represents the results obtained by Matthiessen, who did not examine any alloy between those containing 16·4 and 85·1 volume per cent of copper. The comparison of Professor Lodge's curve with that given by F. Kohlrausch for mixtures of sulphuric acid and water—which I also append—appears to me to be in the highest degree suggestive. In the case of the latter it will be observed that, starting from SO_3 on the one side and H_2O on the other, minima occur at points on the curve corresponding to compounds of the formula H_2SO_4 and $H_2SO_4.H_2O$; it is, however, well known that such compounds are unobtainable at ordinary temperatures, and it is highly probable that if the *pure* compounds could be examined, the minima would touch the base line, as in the case of water. The point of maximum conductivity does not correspond to any known hydrate, but as I have elsewhere remarked it is almost coincident with that of maximum heat evolution on mixing sulphuric acid and water, and it is therefore doubtless the point at which the maximum chemical change occurs. On reference to the alloy curve it is seen that the addition of quite a small amount of tin to copper produces a very marked effect, just as does the addition of a small amount of water to sulphuric acid, the result being, however, to diminish conductivity in the one case but to increase it in the other; after the addition of only a moderate amount of tin a pronounced minimum is reached, corresponding to the pronounced maximum attained on addition of a moderate amount of water to sulphuric acid, and at a point moreover corresponding to a definite compound, $SnCu_4$. A further slight addition of tin develops another minimum less pronounced than the first, but also corresponding to a definite compound, $SnCu_3$; the curve then falls slightly and exhibits a third minimum, its course being analogous to that of the sulphuric acid and water curve near to sulphuric acid. If one or the other curve be inverted the general similarity in form is especially striking. It is obviously important that alloys intermediate between those studied should be examined; a comparison of Lodge's with Matthiessen's curve shows how much may be missed; this remark applies to alloys generally. Whatever may be the explanation,* it appears to me to be clear that in alloys as in composite electrolytes the constituent members of the system influence each other, and thus mutually contribute to the final result. The marked diminution in the conductivity of copper produced by very small quantities of oxygen, of phosphorus, and of the metalloid arsenic is well known. It would appear probable that this is in some way due to the occurrence of an electrolytic change, which at least in part is opposed in direction to that taking place in the pure metal during conduction.*

(To be continued).

* It is very remarkable that not only do the heat conductivity and the induction balance curves for the tin-copper alloys correspond (Chandler Roberts, *Phys. Soc. Proc.*, iii., 156), but that the curves given by Thurston as representing the strength of these alloys ("Materials of Engineering," Part III., p. 412) also exhibit a marked similarity to the electrical conductivity curves.

ON THE DETERMINATION OF ARSENIC.†

By LEROY W. MCCAY.

(Concluded from p. 234.)

HAVING worked so satisfactorily qualitatively, I determined to see whether this method of reduction could not be made to take the place of that suggested by Holthof, it being plain that, should its practicability prove incontestable, the Mohr-Holthof process would be wonderfully improved, especially in respect to the time necessary for making a reduction. When working according to Holthof, considerable quantities of sulphurous acid and *four* hours are requisite for complete reduction; whereas by subjecting the arsenic acid under pressure to the reducing influence of the sulphurous acid, the reduction is accomplished in *one* hour. It is just here that I propose to modify the method.

Since the reduction of arsenic to arsenious acid with sulphurous acid is, when all the details above indicated are strictly observed, not only complete, but also capable of being carried out in a remarkably short period of time it seemed feasible to make a few estimations of the element as the sulphide, this method of determining the arsenic being especially applicable in the case of a solution containing pure arsenious acid, and free from all substances possessing the property of acting in a reducing manner upon sulphuretted hydrogen.

The determinations were made by bringing the solution of H_2KAsO_4 into a little bottle of convenient size, adding somewhat over an equal volume of *strong* sulphurous acid and reducing, then boiling down one-half after transferring to a flask, and precipitating the arsenic in a beaker with freshly prepared sulphuretted hydrogen water. The solution when ready for precipitation should be moderately hot, strongly acid, and its volume should equal about 100 c.c. The freshly prepared and perfectly clear sulphuretted hydrogen water is to be added in slight excess, and the solution, after the addition of the same, heated on the sand-bath to about 80° to 85°, and kept at this temperature, with occasional stirring, until the precipitate of the sulphide settles completely, leaving the supernatant fluid clear, and emitting but a faint odour of sulphuretted hydrogen. The filtrates, although invariably examined, gave no evidence of the presence of arsenic.

Friedrich Mohr, in his *Lehrbuch der Titrirmethode*, IV. Auflage, s. 357, uses the following language: —"When the arsenic as arsenic trisulphide is once gotten upon the filter-paper, nothing is simpler than to dissolve the same off the paper in ammonic hydrate and evaporate the resulting solution to dryness in a watch-glass or porcelain dish. I have satisfied myself that *dry* arsenic trisulphide when weighed in a platinum dish, dissolved in ammonic hydrate, and again evaporated to dryness, gives exactly the same weight. From 0·243 grm. As_2S_3 I obtained 0·243 grm., from 0·643 grm. I got back 0·642 grm. It is only the filter-paper which hinders the weighing and drying, and this is here done away with." Neither Rose, Fresenius, nor Classen recommends this method of treating the precipitate of the sulphide, and I therefore thought it

* The change produced in gold by a very small quantity of lead is most astonishing: its conductivity is reduced almost to that of lead, and it becomes as brittle as glass. It is difficult to understand this change unless it be that opportunity is given for the gold itself to assume a different molecular state owing to continuity becoming disturbed. The effect produced appears to be strictly comparable with that observed on lowering the temperature of silver iodide from above about 150°, and in the passage of liquid water at 0° into ice.

† *American Chemical Journal*, vol. vii., No. 6.

well to put it to the test. I made six determinations, the ammoniacal solution being caught, evaporated, and weighed in a thin light platinum dish. The sulphide was not dried, but dissolved off the paper as soon as the washing was finished. Mohr's experiments were made on the *dry* sulphide, although from his directions one would conclude that he advocated too the direct application of the ammonia to the still moist precipitate. Whether or not correct results would be obtained by first drying and then dissolving the precipitate I am unable to say. The following are the results of my experiments:—

	St. Sol.	As_2S_3.	As.	As_2O_3.	As_2O_5.
1	10 c.c.	0·0965 grm.	0·0588 grm.	0·0776 grm.	0·0901 grm.
2	10	0·0955	0·0582	0·0768	0·0892
3	10	0·0963	0·0586	0·0774	0·0898
4	10	0·0945	0·0576	0·0759	0·0883
5	10	0·0985	0·0600	0·0792	0·0920
6	10	0·1003	0·0611	0·0806	0·0936

10 c.c. 0·0593 grm. As = 0·0782 grm. As_2O_3 = 0·0907 grm. As_2O_5.

The above results are not only incorrect, but they exhibit no constancy among themselves, in spite of the fact that in all cases extreme care was taken to work under like conditions. During the evaporation of the ammoniacal solution, one of the first things which attracted any attention was an evolution of sulphuretted hydrogen, which continued until the last traces of moisture had disappeared and the residue exhibited a perfectly dry appearance. The presence of the sulphuretted hydrogen could be distinctly indicated by the change of colour to brown, and in some cases almost to black, of a piece of filter-paper moistened with a little acetate of lead solution, and held over the platinum dish containing the solution of arsenic. The figures above given show conclusively that Mohr's proposal is inapplicable, at all events in the case of freshly precipitated and still moist trisulphide of arsenic. Numbers 1, 2, 3, and 4 are too low; number 5 is very nearly correct; while number 6 is too high. In Roscoe and Schorlemmer's "Treatise on Chemistry," vol. i., p. 538, I find that no less a man than Wöhler directs that the sulphide of arsenic obtained in *forensic work* be dissolved off the filter-paper in ammonia, the resulting solution evaporated in a dish, and the element weighed as the trisulphide, As_2S_3. *No mention whatever is made of its being necessary first to dry the precipitate.* It is a very remarkable fact that the evolution of sulphuretted hydrogen during the evaporation of the ammoniacal solution should have escaped the notice of Mohr and Wöhler, and it is likewise a remarkable fact that no one has yet seen fit to call attention to the inaccuracy involved in weighing the arsenic as the compound obtained by evaporating an ammoniacal solution of the trisulphide.

However, by following the usual method, collecting, drying, and weighing on a tared paper, very satisfactory results were obtained, as the figures below given will at once show. I find it well, after a thorough washing, to remove the adhering water by means of about 10 c.c. of absolute alcohol, so as to hasten the subsequent drying of the precipitate. The sulphide was weighed in a very light drying-box provided with a well-fitting ground-glass stopper.

	St. Sol.	As_2S_3.	As.	As_2O_3.	As_2O_5.
1	20 c.c.	0·1935 grm.	0·1180 grm.	0·1553 grm.	0·1810 grm.
2	20	0·1930	0·1176	0·1550	0·1802
3	20	0·1940	0·1182	0·1560	0·1812

20 c.c. = 0·1186 grm. As = 0·1564 grm. As_2O_3 = 0·1814 grm. As_2O_5. With 50 c.c. H_2KAsO_4 solution I obtained 0·4869 grm. As_2S_3 = 0·2963 As = 0·391 As_2O_3 = 0·4527 As_2O_5.

I shall now retnrn to my modification of the Holthof method of reduction.

To avoid, then, the large quantities of sulphurous acid necessary when working according to Holthof, and, moreover render it possible to effect the reduction of the arsenic from the maximum to the minimum stage of oxidation in one-fourth the time hitherto considered requisite, I suggest that Holthof's method be so modified that the reduction be accomplished in hermetically sealed bottles and at a temperature equal to that of boiling water. Qualitative as well as gravimetric quantitative experiments have already proved the reduction to be fully as complete as the one proposed by Holthof; and since its advantages over the Holthof method have been clearly pointed out, it only remains for me to offer a number of test analyses, obtained under various conditions, by titrating different quantities of known solutions of reduced arsenic acid with $\frac{1}{10}$ normal iodine.

A. 1.—In making the following lot of tests the solution of H_2KAsO_4 was brought into a small bottle provided with a well-fitting ground glass stopper, and capable of holding when filled 50 c.c.: 20 c.c. of sulphurous acid were added, the bottle was tightly stoppered, and the stopper firmly tied down with a piece of stout cord. The bottle with its contents was then placed in the *briskly* boiling water-bath, and here permitted to remain for exactly one hour. At the end of this time the bottle containing the arsenious acid was removed from the bath, permitted to cool to such a degree that it caused no inconvenience when held in the hand, and then carefully opened. The solution was emptied into a small flask, the bottle well rinsed out with pure water, and the entire liquid diluted to 150 c.c. After introducing the platinum spiral, boiling down to one-half the original volume, cooling, and diluting to 300 c.c., the arsenic was determined by titrating with $\frac{1}{10}$ normal iodine in the manner already described.

A. Using 5 c.c. H_2KAsO_4 solution, 20 c.c. sulphurous acid, and reducing as above, I obtained—

No.	St. Solut'n.	1-40 Normal Iodine.	As.	As_2O_3.	As_2O_5.
1	5 c.c.	15·80 c.c.	0·0297 grm.	0·0392 grm.	0·0456 grm.
2	5	15·80	0·0297	0·0392	0·0456
3	5	15·65	0·0294	0·0389	0·0452
4	5	15·75	0·0296	0·0391	0·0455
5	5	15·80	0·0297	0·0392	0·0456
6	5	15·65	0·0294	0·0389	0·0452
7	5	15·80	0·0297	0·0392	0·0456
8	5	15·80	0·0297	0·0392	0·0456
9	5	15 70	0·0295	0·0390	0·0453

5 c.c. = 0·0296 grm. As = 0·039 grm. As_2O_3 = 0·0453 grm. As_2O_5.

2. Using 10 c.c. HK_2AsO_4 solution, 20 c.c. sulphurous acid, and reducing, I obtained—

No.	St. Solut'n.	1-40 Normal Iodine.	As.	As_2O_3.	As_2O_5.
1	10 c.c.	31·4 c.c.	0·0591 grm.	0·0781 grm.	0·0907 grm.
2	10	31·5	0·0593	0·0783	0 0910
3	10	31·5	0·0593	0·0783	0·0910
4	10	31·45	0·0592	0·0782	0·0908
5	10	31·5	0·0593	0·0783	0·0910
6	10	31·4	0·0591	0·0781	0·0907

10 c.c. = 0·0593 grm. As = 0·0782 grm. As_2O_3 = 0·0907 grm. As_2O_5.

3. Using 20 c.c. H_2KAsO_4 solution, 30 c.c. sulphurous acid, and reducing, I obtained—

No.	St. Solut'n.	1-40 Normal Iodine.	As.	As_2O_3.	As_2O_5.
1	20 c.c.	62 5 c.c.	0·1177 grm.	0·1556 grm.	0·1805 grm.
2	20	62·7	0·1181	0·1559	0·1811
3	20	62 65	0·1180	0·1557	0·1808

20 c.c. = 0·1186 grm. As = 0·1564 grm. As_2O_3 = 0·1814 grm. As_2O_5.

B. To test the method still further, six determinations were made with the solution containing 2·475 grms. As_2O_3,

as As_2O_5, in a litre. 20 c.c. were used in each test, and the reduction was effected in the usual way. I obtained—

No.	St. Solut'n.	1-40 Normal Iodine.	As.	As_2O_3.	As_2O_5.
1	20 c.c.	19·9 c.c.	0·0375 grm.	0·0495 grm.	0·0575 grm.
2	20	19·8	0·0373	0·0492	0·0572
3	20	19·8	0·0373	0·0492	0·0572
4	20	19·85	0·0374	0·0493	0·0573
5	20	19·8	0·0373	0·0492	0·0572
6	20	19·8	0·0373	0·0492	0·0572

20 c.c. = 0·0375 grm. As = 0·0495 grm. As_2O_3 = 0·0575 grm. As_2O_5.

These figures are a trifle lower than those obtained when the reduction was effected by Holthof's method. 20 c.c. of the above solution should require exactly 19·9 c.c. $\frac{1}{40}$ normal iodine, whereas the quantity actually used when following Holthof's directions was 20·1 c.c. I have already given good reasons for believing that in this case the excess of iodine is due to organic substances which are present in the large quantities of water necessary in making a test in accordance with the first method.

Some time last year we received from a firm in Philadelphia a sample of what purported to be arsenic acid, c.p. A quantitative test proved, however, that it was in nowise chemically pure arsenic acid, but a mixture of arsenious and arsenic acids. The comparatively small precipitate obtained with magnesia mixture indicated clearly that the arsenious acid was the principal constituent. The article is in lumps, some of which, owing to their porcelain-like appearance, are immediately recognised as arsenious acid. I have examined this *so-called* arsenic acid by my modifications of the Reich and Mohr-Holthof methods, and in the following manner :—A portion of the material was finely pulverised, 3·0 grms. were carefully weighed out, dissolved in a little warm caustic potash, and diluted to a litre. 20 c.c. were then brought into a beaker, evaporated to dryness upon the water-bath three times with fuming nitric acid, and the arsenic determined according to my last modification of the Reich process. I obtained 0·0558 grm. As_2O_3, which represents the total arsenic calculated to arsenious oxide.

In the following table I give the results of six determinations of the actual amount of As_2O_3 present, each determination being made according to Mohr, and with 20 c.c. of the original solution :—

No.	Solution.	1-40 Normal Iodine.	As_2O_3.
1	20 c.c.	18·2 c.c.	0·0452 grm.
2	20	18·15	0·0451
3	20	18·2	0·0452
4	20	18·2	0·0452
5	20	18·25	0·0453
6	20	11·15	0·0451

Since 20 c.c. = 0·0452 grm., 1000 c.c. = 2·260 grms. As_2O_3, or 3·0 grms. substance = 2·26 grms. As_2O_3, which gives 75·33 per cent As_2O_3.

The table below presents the results of six more determinations, the 20 c.c. solution taken being first reduced under pressure with sulphurous acid, then boiled down one-half, and finally titrated :—

No.	Solution.	1-40 Normal Iodine.	As_2O_3.
1	20 c.c.	22·6 c.c.	0·0562 grm.
2	20	22·6	0·0562
3	20	22·4	0·0557
4	20	22·4	0·0557
5	20	22·4	0·0557
6	20	22·4	0·0557

As present as As_2O_3, according to Reich, 0·0558 grm ; 0·0557 − 0·0452 = 0·0105 grm. arsenious acid present as arsenic acid. Inasmuch as 99 As_2O_3 = 115 As_2O_5, 0·0105 grm.

$$As_2O_3 = \frac{115 \times 0{\cdot}0105}{99} = 0{\cdot}0122 \text{ grm. } As_2O_5.$$

Since 20 c.c. = 0·0122 grm. As_2O_5, 1000 c.c. = 0·610 grm., or 3·0 grms. substance = 0·610 grm. As_2O_5, which gives 20·33 per cent As_2O_5. The rest is undoubtedly moisture. A small sample of the substance when heated gently in a glass tube closed at one end gave quite a strong reaction for water.

In closing I would like to say that, although the Mohr-Holthof method is most admirably adapted for estimating arsenic in such compounds as soluble salts, yellow and red arsenic glass, and mixtures of arsenious and arsenic oxides, for determining the element in minerals, speisses, mattes, and slags, the modified Reich method is, to my mind, much to be preferred. The latter method, though possibly not so *scientifically* perfect as the former, is certainly more rapid, convenient, and practical. Above all things it is singularly well suited for determining arsenic in the various kinds of metallurgical products. I have almost finished an exhaustive examination of this method, and I trust ere long to be in the position to describe the results obtained.

ON THE

UNIT USED IN CALCULATING THE ATOMIC WEIGHTS.*

By LOTHAR MEYER and KARL SEUBERT.

THE controversy arising immediately after the proposal of Dalton's atomic theory, as to the unit upon which the numerical values of the atomic weights should be based, has for a half-century divided chemists into two schools. While Dalton and later Leopold Gmelin, from theoretical and philosophical considerations, chose the smallest atomic weight, that of hydrogen, as the measure of all the rest, Wollaston and Berzelius chose that of oxygen, partly because they did not place so high a value on theoretical views, partly and especially on the purely practical ground that many elements can be compared directly with oxygen, whereas they can be only indirectly compared with hydrogen. When the Dalton unit, the hydrogen atom, gradually obtained the upper hand, the old controversy appeared to have been laid aside, and consequently it was to be hoped that the recent more exact investigations of the laws which govern the numerical values of the atomic weights would be directed from the same point of view.

This hope, however, has unfortunately not been fulfilled, as the old Wollaston-Berzelius unit has lately again come into use in a different, and as we believe more dangerous, form.

As is well known, J. S. Stas† has, from his own observations as well as those of others, deduced, as the most highly probable result, that the atomic weight of oxygen is not quite sixteen times as great as that of hydrogen, but, on the contrary, is about 1-400th of its value less than 16H. This follows :—

(1) From the numerous gas analyses (reduced to weight) conducted since the discovery of Gay-Lussac and Von Humboldt, or, what amounts to the same thing, from Avogadro's law and the experimentally determined densities of both gases (No. 1 *a*,‡ and Julius Thomsen, *Berichte der Deutschen Chemischen Gesellschaft*, iii., 927) ;

(2) From the synthesis of water by means of copper oxide (*loc. cit.*, No. 1 *c*, *d*) ;

(3) From the relations of sal ammoniac to silver nitrate and of both to silver (*ib.*, No. 47 and 83), where, as confirmatory of the atomic weight of nitrogen (N = 0·87791O) used in the calculations, the relations of the chlorides and metals to the nitrates could also be determined (No. 131,

* Translated by W. S. Bayley from an article in the *Berichte der Deutschen Chemischen Gesellschaft*, xviii., 1089.

† "Nouvelles Recherches sur les Lois des Proportions Chimiques." Bruxelles, 1865, p. 24, &c.

‡ "Die Atomgewichte der Elemente aus den Originalzahlen berechnet," von L. Meyer und K. Seubert. Leipzig, 1883.

132, 133, 135); and further, though with somewhat less certainty,

(4) From the relation of the crystallised and dehydrated strontium chlorides to each other and to silver (No. 65 *c* and 140);

(5) From the relation of these substances to each other and to the sulphate (No. 197);

(6) From the corresponding numbers for crystallised and dehydrated barium chloride and silver (No. 66 *e* and 141);

(7) From the relation of both forms of barium chloride to the sulphate (No. 188 *d*);

(8) From the relation of aluminium to hydrogen and to water (No. 8 *c*, *d*, and 144).

The determinations deduced from methods 1 and 2, undoubtedly the most exact, give as a mean the ratio—

$$H : O = 0{\cdot}06265 : 1 = 1 : 15{\cdot}96,$$

which Stas considered as coming nearest to the truth. The simple ratio of 1 to 16 demanded by Prout's hypothesis in one sense lies entirely outside of the observed values, in another sense very near to their extreme limits. To an unprejudiced judge not biassed in favour of that hypothesis, not yet established by the best observations, there appears no ground for accepting this numerical relation rather than that obtained as the mean value.

Further, if the simpler ratio be accepted, the experiments embraced under the heads from 3 to 8 yield results almost all of which agree less well than if the more complex ratios were accepted, and the differences between the calculated values and those obtained under 3 are greater than could be accounted for on the supposition that they are due to errors of observation.

But since this relation between the atomic weights of hydrogen and oxygen had not yet been as accurately determined as that of other elements to one another, Stas, in order to show the utter indefensibility of Prout's hypothesis, calculated all the atomic weights determined by him upon the assumption, *incorrect according to his opinion*, that the atomic weight of oxygen is just sixteen times as great as that of hydrogen. He pointed out that, even with this assumption, Prout's hypothesis would not hold good for the rest of the atomic weights under investigation. This supposition, made by Stas merely for the sake of argument, appears to have been much misunderstood; as if the value O = 15·96 and O = 16·00 were exactly the same, which of course is not at all the case. It is rather in a high degree probable, if not certain, that the number 16 is incorrect to 3 or 5 units in the second decimal place, whereas the other value, 15·99, is out only 1 or at the most not more than 2 units.

Since we were at that time accustomed to reckon with O = 16, and Stas naturally discussed only those atomic weights which had been newly determined by him, the choice was offered whether to calculate all atomic weights with the corrected values of oxygen, silver, chlorine, &c., as a basis, or provisionally to manage further with the old numbers, and merely introduce the corrected atomic weights of Stas into a system resting upon a somewhat more defective basis. This last, incorrect indeed, but more convenient way, was chosen by many chemists. This could the more easily be done since most of the atomic weights in use at that time were justly looked upon as not being very accurate, and a difference of 1·400th of a value was of very little practical consideration.

The hope that at least the old controversy over the choice of the unit would disappear upon a re-calculation of the atomic weights of all the elements has unfortunately not been fulfilled. There is a universal desire to do away with the unit preferred by Thomsen, Wollaston, and Berzelius,—

$$O = 1, = 10, \text{ or } = 100,$$

and to refer all atomic weights to hydrogen. But as to the way in which this should be done opinions differ. With a few exceptions (as in the case of Al, No. 8 *c*, *d*) the relation to hydrogen is deduced only through the intervention of oxygen,—consequently the numerical values of all atomic weights depend upon that of oxygen. In consideration of this we have, in our re-calculation of the atomic weights referred to above, made use of the Wollaston-Berzelius unit (O = 1), as well as the usual one (H = 1), so that in case of a new, more trustworthy determination of the relation O : H, the numbers referred to hydrogen as 1 could easily be corrected. A few years earlier G. F. Becker* referred all the atomic weights to O = 16. F. W. Clarke† has, like us, taken H = 1, but has also, out of fondness for Prout's hypothesis, given a table in which O = 16, and consequently H = 1·0023. J. Sebelin‡ makes use of the same units as we do (H = 1 and O = 100), and only occasionally adds a few numbers calculated on the supposition that O = 16. W. Ostwald§ does not agree with Stas that the value O = 16 is too large, but thinks that, from the last five observations of Erdmann and Marchand,‖ the first three of which he casts aside, it must follow that for H = 1, O must be exactly 16·00, though the sum of all the experiments of these authors gives O = 15·96. J. D. van der Plaatz¶ inclines to the view that O may be equal to 16, though he considers the question as still open. W. Dittmar** has re-calculated the atomic weights, calculated by us on the basis H = 1, on the basis O = 16, and H = 1·0024.

In consequence of these different views all the other atomic weights fluctuate to the extent of about ½ per cent of their value, amounting in the case of the largest to one-half of the unit. That such a condition of things is undesirable all scientific men are agreed, and also that the very smallness of the difference aids in the confusion and perplexity, since every author will not state, in every article, the standard according to which he calculates.

How the evil is to be remedied is difficult to say. First of all it is to be remembered that both values for the atomic weight of oxygen lie within the limits of errors of observation, and that, in case authenticated constant errors tend to lower the result, it may even be admissible to take the maximum value O = 1603, instead of the mean value O = 15·96. It is more questionable, however, to round off this maximum value just at the number 16, for which there are no grounds except the unproven Prout's hypothesis. The secret or confessed fondness for this hypothesis is probably the true cause of the choice of this number. We willingly acknowledge that there may be concealed in this hypothesis of Prout's a valuable idea; but this does not change the fact that, *as now stated, the hypothesis is untenable*. Wherever, up to this time, the proof has been looked into with sufficient exactness, it has shown that the atomic weights are not exact multiples of whole numbers, and this result is independent of the relation of oxygen to hydrogen. Accept this or not, as we will, we always obtain for the atomic weights, when most accurately determined, irrational numbers.

What seems to be most noteworthy in Prout's hypothesis is brought into view, and in an unprejudiced manner, when we take the relation of H : O as given by the most accurate observations. For instance, it is a striking fact that that the atomic weights of more than one-fourth of all the elements are very nearly multiples of the half atomic, or equivalent weight of oxygen, as the Table will show. (See next page).

Such regularities are worthy of note; but to attempt to correct the atomic weights by them would be just as incorrect as to round them off into whole numbers.

He who does not adhere to Prout's hypothesis, and is besides not of the opinion that the observations yield as the most probable value of the relation O : H = 16 : 1, has, according to our view, not the least ground for giving the value O = 16 the preference over O = 15·96. Then, if we take the atomic weight of oxygen, not as = 1 or = 10 or = 100, but as = 16, the only meaning that can be attached to it is that it appears more proper to take the hydrogen atom as the unit. This view is universally held; but since its relation to oxygen is uncertain to a few thousandths of its value, it is thought that the round number 16 may be used instead of the 15·96 found, though it is necessary in this case to place H = 1·0025, *i. e.*, to take as the unit $\frac{1}{1\,0\,0\,2\,5}$ of the atomic weight of hydrogen. Such a wonderful unit can only be endured in the quiet hope of the future fulfilment of the hypothesis of Prout. In the end hardly anyone will seriously wish Science to be burdened with it.

It is admitted that with the atomic weight of oxygen uncertain, all others remain so likewise in the fourth and following places of their numerical values, while their relative values, their relations to one another, in many cases are correctly determined to the fourth, and in some cases even to the fifth, place. These facts can be changed by no hypothetical considerations. If to-morrow the relation O : H should be determined more accurately to the one or two thousandth part of its value, and this number should differ from the one accepted to-day, all the other atomic weights would have to be re-calculated.

What advantage is offered in calculating with H = 1·0025 and O = 16 we cannot possibly see. The fact that the numerical values for oxygen, carbon, and a few other elements are thereby reduced to two figures, can hardly appear so desirable that one should, for this reason, consent to the choice of such a nonsensical unit.

It has been stated that the error which would be introduced by making H = 1 is much smaller than the unavoidable errors of observation.

But so far as this is concerned it may, on the other hand, be asked—Why introduce even so small an error when it can be avoided? Our observations are, without this, already sufficiently subject to sources of errors of all kinds. It does not change the case at all if the omission of these small fractions does *not* influence the decimal places which are generally considered in analysis. If for most *inorganic* compounds no difference of importance is effected, in the case of the analysis of *organic* compounds it is otherwise.

In this field no one would be expected to reckon with H = 1·0025. After H has once been decided upon as = 1, it makes quite a difference in the result whether O is taken as 15·96 and C as 11·97, or O as 16 and C as 12. In some cases this difference is greater than the difference in the composition of closely related compounds.

The table given below shows the percentages of hydrogen and carbon in the paraffins containing 30 and 31 carbon atoms and their derived alcohols and acids (myricyl alcohol and melissic acid*), and also the amount of water and carbon dioxide produced in their combustion. Under *a* are the results calculated with O = 15·96, C = 11·97; under *b* with O = 16 and C = 12.

Thus we see that the amount of water remains almost the same in each calculation because the variations compensate each other; the hydrogen, on the other hand, varies a few hundredths, as does also the carbon, while the variations in the carbon dioxide reach the tenths of a per cent, *a difference which is often greater than that obtained from two adjacent hydrocarbons in a homologous series*. This last is more clearly seen if we calculate by both methods the percentages of carbon and dioxide contained in a series of hydrocarbons, and place them together as is done in the following Table :—(See next page).

This shows that the different calculations *a* and *b* may lead to different interpretations of the analyses. If, for instance, the combustion of a hydrocarbon yields 312·51 m.grms. of carbon dioxide for every 100 m.grms. of substance, the advocate of Prout's hypothesis will find that the formula $C_{25}H_{52}$ best expresses the result of the analysis, while according to Stas and his followers it indicates the formula $C_{27}H_{56}$. Of course no one would determine the formula of such a body by means of analysis alone; still one is accustomed, in the choice of formulas, to lay a certain weight on the mean result of a series of closely agreeing analyses, and this would here lead to a false conclusion if an error of a few thousandths in the atomic weight of hydrogen were not thought worthy of account.

Those who think with us that the determinations thus far submitted render more probable the relation—

O : H = 15·96 : 1 = 1 : 0·06265,

than that demanded by Prout's hypothesis,—

O : H = 16 : 1 = 1 : 0·06250,

are guilty of a dangerous inconsistency when they operate with such atomic weights as—

O = 16, C = 12, Cl = 35·46 or even 35·5, &c.

These may, of course, be used in the laboratory for the calculation of approximate results, as in the case of preparing substances; but when it comes to calculating accurate analyses they should not be used.

We may ask of the admirers of Prout's hypothesis whether the universal acceptance of a uniform basis for all atomic weight determinations is not of much more value than a supposition which, in a few cases, may possibly not be entirely erroneous.

We are all convinced that the relation under consideration (and thereby every other atomic weight referred to H = 1) is not accurate to the thousandth part of its value. Let us accept it without artificial interpretations, just as it is yielded as the mean value of agreeing results obtained in many different ways, and wait till the future for its further proof and confirmation by experimental methods. As soon as this is accomplished we will be ready, among the first, to accept any changes in the values of the atomic weights as now calculated that may then be deemed necessary.—*American Chemical Journal.*

TWO NEW FILTERS AND A NEW ASPIRATOR.*

By P. CASAMAJOR.

I PROPOSE to describe two new filters which I have lately used with advantage, and also an apparatus for starting an aspirator. This apparatus may be applied to one of the new filters described or to others working in a similar manner.

One form of filtering apparatus is shown in section in Fig. 1. The vertical portion is a tube open at the top. The horizontal portion is a circular disc provided with a few holes to establish communication between the upper and lower surfaces of the disc. Below the disc horizontal openings are made to allow the vertical tube to communicate with the space below the disc. The vertical tube may have the same diameter throughout, but the walls of the tube are thicker in the lower portion than in the middle, and in this thicker than in the upper. The tube does not taper uniformly on the outside, but there is a shoulder between each portion and the one above it, the lower shoulder being designed to hold the disc in its place.

The filtering medium used with this apparatus is a circular piece of cloth, the centre of which is placed under the vertical tube. The cloth is folded over the edge of the disc, so that the edges of the cloth meet above the shoulder between the middle and upper portion of the tube. These edges are fastened above this shoulder by means of a string or a wire. The upper portion of the vertical tube may then be connected with a rubber tube.

To use this apparatus it may be placed in a vessel containing the liquid to be filtered. The rubber tube attached to the vertical tube may pass over the edge of the tank and be prolonged downwards on the outside below the position of the filter in the liquid. The syphon formed in this way may be started by suction. The liquid to be filtered passes through the cloth and outwards through the rubber tube.

* From the *Journal of the American Chemical Society*, vol. vii., No. 4.

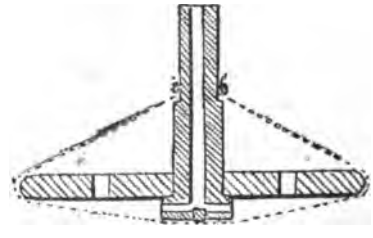
Wood is the most convenient material for making this filter. It has the drawback that it floats, which may be remedied by attaching a weight to the portion shown in Fig. 1.

For certain purposes this portion may be made of metal—iron, lead, tin, &c. Instead of pure lead, an alloy of lead 90 parts, antimony 10 parts, tin 5 parts, will be found to be harder and sufficiently tough.

This filtering apparatus is applicable to manufacturing operations on a small scale rather than to laboratory work.

The second form of filter is one which I have had in use for some time. I have named it the *sand poultice*. It is a bag full of sand *through* which the liquid to be filtered has to pass. The bag holding the sand is made of two circular pieces of cloth, whose edges are sewn to a strip of cloth about 1½ inches wide. After this bag has been filled with sand it has the shape of a flat circular box.

Fig. 1



When in use this sand poultice must lie on a perforated surface in a cylinder. The poultice is made of such a size that, when pressed down on the perforated surface, the vertical edge, formed by the strip of cloth, presses tightly against the cylindrical surface. It is to obtain this tight fit that the strip of cloth is used, and that the bag has not been made by sewing together the edges of the two circular pieces of cloth.

When this filter was first used it was found impossible to dislodge a certain amount of air which inflated the upper covering of the sand poultice. This was afterwards avoided by making a slit in this portion of the cloth through which the air escaped. A certain portion of dirt is in consequence deposited on the sand instead of on the cloth; but this has not been found practically objectionable.

Under the perforated plate supporting the sand poultice is a space for the collection of filtered liquid, which may very conveniently be let out by a faucet. With the sand may be mixed powdered charcoal, bone-black, &c. The sand poultice may be taken out and washed as often as is desirable, and the bag may be refilled when necessary.

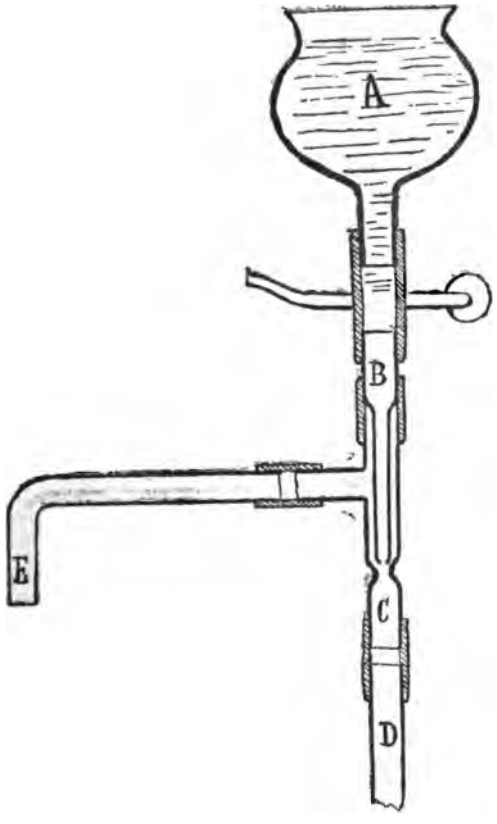
During the late period of turbidity in the Brooklyn water supply I have had occasion to use the sand poultice for filtering water for domestic use. I have found it advantageous to have a layer of fine gravel on top of the poultice, to arrest the greatest part of the muddy deposit and prevent it from obstructing the cloth. This gravel was taken out and washed twice a week without disturbing the rest of the filter. After being washed, the gravel was put back on top of the bag. After doing this five times it was found necessary to take out the poultice itself to wash the cloth covering.

Apparatus for Starting a Syphon.

This apparatus was suggested by a very ingenious ar-

rangement used in Dr. E. R. Squibb's acetic acid works. I have his permission for describing it here. In these works the acid is stored in very large stoneware receivers, which have no opening at the bottom, but they are provided with two tubulures on top. Through these tubulures pass glass tubes which go to the bottom of the receivers. Every tube is connected with a similar one on the receiver next to it by means of a bent connecting-tube. These three tubes, held together by means of rubber tubes, form an inverted U. On top of the bent tube is a tubulure over which passes a rubber tube, which is closed or opened by means of a pinch-cock. Through this tubulure the inverted U is filled by pouring in acid, after which the pinch-cock is closed. The last tube of a train connects in a similar manner with a vertical glass tube which extends to the storey below. This vertical tube ends, on its

Fig. 2



upper portion, in a T, one branch of which connects with the tube in the last receiver of the train. The upper end of the T has a rubber tube over it, which is closed with a pinch-cock. When it is desired to draw acid from the train of receivers, this pinch-cock is opened, and acid is poured in a funnel above the pinch-cock. The vertical tube is filled, the pinch-cock closed, and the acid, in running down, forms a syphon, by which the receivers are emptied, either wholly or in part, as may be desired. When sufficient acid has run out the pinch cock over the long vertical tube is opened, air is admitted, and the flow ceases.

The apparatus shown in Fig. 2 is made by connecting a thistle tube to a tube B by means of a rubber pipe closed by a pinch-cock. The lower end of tube B is placed above a reduced portion of tube C. When water runs down from the thistle tube by opening the pinch-cock, an aspiration is produced in tube C. The horizontal branch of the T tube C connects with a filtering apparatus, which may be the one represented in Fig. 1. It is also applicable to Dr. Carmichael's filter, or to the filter described by me in the *Journal of the American Chemical Society*, vol. iii., p. 125, in which the vertical tube causing aspiration is filled by suction from a flask, but the apparatus shown in Fig. 2 is much more convenient.

After filling the thistle tube with distilled water the pinch-cock is opened, and the water rushing downwards from tube B produces a vacuum in tube C connecting with a filter. This soon becomes filled with filtered liquid. In the apparatus in use in my laboratory 3 or 4 c.c. of water are sufficient to start the action by filling the vertical tube below tube C.

This apparatus differs from the one used in Dr. Squibb's works, by the use of the tube B and the narrowing of the tube C below the end of tube B. This addition was found necessary, because when the tube B is not used the opening of the pinch-cock below the thistle tube causes a momentary increase of pressure in the tube C until the vertical tube below C has been filled. This disarranges the asbestos on the platinum plate in the filter described in the *Journal of the American Chemical Society*, vol. iii., p. 125, and the operator is put to much trouble.

ELECTROLYTIC DETERMINATION OF MERCURY.

By DON LUIS DE LA ESCOSURA.

First Process.—The author operates upon about ½ grm. of ore, treated with 20 c.c. of water mixed with 10 to 15 c.c. of hydrochloric acid. The whole is gently heated in a porcelain capsule, and when the liquid is on the point of boiling from 0·5 to 1 grm. of potassium chlorate in powder is added by small portions. When the action is over 50 c.c. of water are added to the liquid, and it is boiled afresh until the odour of chlorine is no longer perceptible. At this moment 20 to 30 c.c. of a saturated solution of ammonium sulphite are added, boiling again for a few minutes; the capsule is then withdrawn from the fire, and let settle. Care must be taken to supply the water which is lost by evaporation. The addition of the ammonium sulphite is to precipitate selenium and tellurium before electrolysing the liquid. After settling for half an hour the liquid is filtered, and the insoluble residue is washed. The volume of the filtrate should be about 200 c.c. This liquid is put in a glass beaker, and the electrodes are introduced. These are plates of metal; the one may be of platinum, but the other which communicates with the zinc pole of the battery must be of pure gold. The plates are suspended vertically in the liquid. The battery consists of two Bunsen elements. In twenty-four to thirty hours the operation is completed; the mercury is deposited upon the gold plate. The increase of weight in this corresponds to the quantity of mercury contained in the weight of metal taken.

Second Process. Direct Electrolysis of the Mercury Ore without previous Solution.—The ore, in fine powder, is placed in a platinum capsule, in a mixture of water, hydrochloric acid, and ammonium sulphite. For a 10 per cent ore the following proportions are employed:—Ore, 0·2 grm.; acid, 10 c.c.; water, 20 c.c.; sulphite, 20 c.c.; so as to make up about 120 c.c. These proportions are modified according to the richness of the ore. The platinum capsule (0·09 metre in diameter) is placed on a support, and a disc of gold of 0·04 metre in diameter is plunged into it; soldered to a rod of gold, communicating with the zinc pole of the battery, the capsule is connected to the other pole. In twenty-four hours the operation is

complete: the mercury is deposited upon the disc of gold, the increase of weight indicating the quantity of the metal.

In preference to a Bunsen battery, Don Luis de la Escosura uses six elements formed of a cylindrical vessel of glass, 0·10 metre in diameter and 0·16 metre in height, in which a zinc disc is suspended by means of two copper wires at two-thirds of the height of the glass above the bottom. At the centre of the zinc disc is a copper wire bent twice at right angles, so that the other extremity of the wire plunges into the glass vessel of the next element. To increase the surface of contact it is well to make the copper wire end in a spiral. The copper wire immersed in the liquid, except the spiral, is coated with an insulating substance.

The glass is filled with plain water after the crystals of copper sulphate have been introduced, and in a few hours the battery is ready for use.

This second process, though much simpler than the first, is strictly accurate, even in the case of very poor ores containing less than 0·1 per cent of mercury. The accompanying impurities do not interfere.—*Journal de Pharmacie et de Chemie.*

NOTICES OF BOOKS.

Cellulose: being a Short Account of the Chemical Properties of Typical Members of the Cellulose Group. with reference to their Natural History. By C. F. Cross and E. J. Bevan. Edited by W. R. Hodgkinson, Ph.D., F.R.S.E. London. Published for the Authors by G. Kenning.

This pamphlet summarises our present knowledge concerning cellulose, to which, as it is well known, the authors have made very important contributions, and it points the way for much important research.

For dissolving cellulose the authors recommend a modification of Schweitzer's reagent, prepared by mixing the substance to be operated upon with copper turnings in a tube contracted below and fitted with a stopcock. The ammonia is poured upon the mixture, drawn off, and returned repeatedly to the tube.

The fact is brought out that the mantles of certain mollusks—*Pyrosomidæ*, *Salpidæ*, and *Phalluria mamillaris*—contain a substance identical in composition and properties with the cellulose of plants.

The compounds of cellulose with oxides of nitrogen, usually viewed as nitro-celluloses, the authors consider as cellulose nitrates, since, unlike the nitro-compounds of other series, they do not yield amido-compounds on reduction with nascent hydrogen.

In representing the gun-cottons or pyroxilines, the authors, to avoid fractions, double the ordinary empirical formulæ. Hence true gun-cotton, the most explosive kind, quite insoluble in mixtures of ether and alcohol, is here described as a hexanitrate, whilst the collodion varieties become tetra- and tri-nitrates.

The two oxy-celluloses, α and β, are very fully described. The former, arising from the action of air, and light, or of bleaching-powder upon cellulose, is sometimes formed unintentionally in the process of bleaching vegetable tissues. It has an increased affinity for basic colouring-matters, and is coloured a bright yellow by warm solutions of phenyl-hydrazine salts. The authors notice its exceptional attraction for vanadium compounds, as combination ensues even when 1 part of the metal in the form of chloride dissolved in 1,000,000,000,000 parts of water is brought into contact with cellulose.

It is well known that man and probably the majority of the higher animals are unable to digest cellulose. The fluid from the vermiform appendage of the cœcum in the rabbit digests cellulose, evolving marsh-gas and forming a compound which reduces cupric oxide in alkaline solutions. The soluble ferment of the foxglove converts cellulose into glucose and dextrine.

The compound met with in jute fibre, which the authors formerly named bastose, they now include under the general heading Ligno-cellulose. They point out that the urine of the Herbivora normally contains hippuric acid or benzoyl glycocine, and the benzoyl-radicle required to form this body by reacting with the glycocine of the liver is a product of the digestion of ligno-cellulose, whilst the latter body contains no benzene compounds as such. Hence a portion of the complex ligno-cellulose molecule is in a potentially aromatic state. Coal itself, it is suggested, may be regarded as a pseudo-carbon derivative formed by a process of molecular condensation. The whole series of aromatic compounds may thus be traced back to a cellulosic origin.

There is very much more in this treatise to which attention might be called. In fact we have rarely had the good fortune to meet with so suggestive a work. The student of technology, of physiology, of organic chemistry as a scientific whole, will here meet with clues which, if duly followed up, will lead to the most important results.

CORRESPONDENCE.

THE DISCOVERY OF OXYGEN.

To the Editor of the Chemical News.

Sir,—Without doubting for a moment that Priestley discovered oxygen on August 1, 1774, I should be glad if you or some other historical chemist would enlighten me as to the following statement which I have culled from an old work on Chemistry:—

"Klaproth, "On the Knowledge of the Chemistry of the Chinese in the Eighth Century," infers that the Chinese were then acquainted with oxygen and the composition of water. The following is interesting:—

"'There are many circumstances purify it (referring to the atmosphere), and which can rob it of part of its *ȳne*; the chief of these are those things which are modifications of the *yânn*, such as the metals, sulphur (*lieôu-hhouânn*), and *tâne*, or carbon. These ingredients, when burnt, amalgamate the *yânn* of the air, and form with it new combinations of two fundamental bases. The *ky-ȳne*, or *ȳne* of the air, is always pure; but by the aid of fire it can be extracted from *tchine-chĕ* (a kind of whetstone), from *hhò-siaō* (nitre), and from *hhĕ-tânn-chĕ*, a black stone* found in the marshes. It enters also into the composition of water, in which it is so closely united with the *yânn* that its decomposition becomes extremely difficult. . . . Gold never amalgamates with the *ȳne* of the air, and is always found native.'"—*Mémoires de l'Académie Impériale des Sciences de St. Petersburgh*, tome ii., p. 476.

Most modern text-books on chemistry take us no further back than Priestley; so that if there be any truth in the above statement it is only fair that it should be noted. Possibly others beside myself may be interested in the matter.—I am, &c.,

Charles W. Duckworth.

Clayton, Manchester.
May 8, 1886.

FILTERING APPARATUS.

To the Editor of the Chemical News.

Sir,—The appearance in the current number of the Chemical News of matter relating to the Gooch filter

* Probably black oxide of manganese.

suggests the mention of an arrangement that I have had in use for some weeks. It consists shortly of the addition to the perforated platinum crucible of a thin external capsule of the same metal, about ⅜ inch deep. The capsule serves the double purpose of excluding reducing gases on ignition of a precipitate, whilst at the same time it collects any small particles that may perchance pass through the perforations. The capsule should fit somewhat tightly over the crucible, and is of course weighed with the latter prior to the collection of a precipitate. The internal diameter of the bottom of the crucible is that of a sixpence, and as a disc of paper whose ash is of almost inappreciable weight may often with advantage replace the asbestos felt the said sixpence serves as a guide for cutting the papers. When paper is used the small filter is easily brought to the upper part of the crucible and there consumed apart from the precipitate.

I may just add that the crucible, whilst the contents are drying and when ignited, is so inclined that the bottom of the capsule rests against one side of the triangle.—I am, &c.,

H.

CHEMICAL NOTICES FROM FOREIGN SOURCES.

NOTE.—All degrees of temperature are Centigrade unless otherwise expressed.

Comptes Rendus Hebdomadaires des Séances, de l' Académie des Sciences. Vol. cii., No. 17, April 27, 1886.

On the Determination of the Organic Carbon contained in Soils which fix Free Nitrogen.—M. Berthelot.—To find the proportion of the organisms which fix atmospheric nitrogen in soils the author, finding their isolation impracticable, determines the carbon constituting their tissues. This is effected by combustion with copper oxide and afterwards with oxygen. In case of sands or clays he operates upon 30 grms. so as to collect about 100 m.grms. of carbon dioxide. For arable soils more rich in carbon a weight ten or fifteen times less is sufficient. The determination of organic hydrogen appears scarcely possible on account of the considerable proportion of water retained by soils dried at 100°, a point which cannot be safely exceeded for fear of altering the organic matter. The determination of the carbon presents a special difficulty on account of the carbonates present in arable soils, which are in part decomposed during combustion. The soils were therefore previously treated with an excess of hydrochloric acid, washed until the chlorides are removed, and dried in the water-bath. A portion of the organic carbon, however, is removed by dilute hydrochloric acid. It appears from the author's analyses that 1 kilo. of the soils which fix nitrogen contains from 1 to 2 grms. of organic matter, constituting the beings which effect the fixation.

Observations on the Proportion and the Determination of Ammonia in the Soil.—MM. Berthelot and André.—The authors observe that the losses of ammonia during the desiccation of soils, even in the cold, are considerable, especially with vegetable earth. The determination of the ammonia contained in soils must not only be effected by means of soda in the cold, but there should be no previous desiccation of the earth. The water must be determined separately in another portion. Soils moistened by rain or by watering tend continually to lose ammonia during their spontaneous drying in contact with air.

Nitrogenous Matters contained in Rain-Water.—MM. Berthelot and André.—It has been customary merely to determine the ammoniacal and the nitric nitrogen of rain-waters. The authors find it necessary to make further two determinations of organic nitrogen, the one in the atmospheric dust removed from rain-water by filtration, and the other in the filtered residue (previously evaporated to dryness) after determining the ammonia by Boussingault's method.

Rotatory Magnetic Power in Crystalline Bodies.—M. Chauvin.—The author remarks that in 1845 Faraday found all double refractive crystals inactive. Becquerel, Bertin, and Lutdge have since found this conclusion too general, and the author has now recognised a rotatory power even in Iceland spar.

Action of Alcoholic Potassa upon Urea, Sulphurea, and certain Substituted Ureas. Inverse Reaction to that of Wœhler.—Alb. Haller.—The author has studied the action of potassa upon urea, sulphurea, and certain substituted ureas. On cooling the tube was found lined with crystals of potassium cyanate. Hence these bodies, in an alcoholic medium, present a reaction the inverse of that by which their synthesis is effected.

Two Properties of the Urethanes of the Fatty Series.—G. Arth.—The author has previously shown that ethyl carbamate, on treatment with an alcoholic solution of potassa, yields potassium cyanate, alcohol, and water. The same reaction takes place with isobutylic, amylic, and caprylic ethers. All these, if treated in the same manner furnish an abundant precipitate of potassium cyanate with regeneration of the primitive alcohol. Octyle carbamate, prepared by the reaction of cyanogen chloride upon caprylic alcohol, yields on distillation at 230° to 232° a residue possessing the characters of cyanuric acid.

Abnormal Secretion of the Nitrogenous Matters of Yeasts and Moulds.—MM. Gayon and Dubourg.—The hypersecretion of nitrogenous matter under the influence of concentrated saline solutions is correlative to an increased production of soluble ferment.

No. 18, May 3, 1886.

On Magnetisation.—M. Mascart.—A mathematical paper, not susceptible of useful abridgment.

Formation of Oxalic Acid in Vegetation: Study of Rumex acetosa.—MM. Berthelot and André.—The authors propose to treat of the formation of oxalic acid in four selected plants, *Rumex acetosa*, *Chenopodium quinea*, *Amaranthus caudatus*, and *Mesembryanthemum crystallinum*. They confine themselves in this memoir to the *Rumex* alone.

Remarks on the Communication of MM. Berthelot and André relating to the Proportion and the Determination of Ammonia in Soils.—M. Schlœsing.—The author points out that he has not applied his process for determining ammonia to vegetable soils, and still less has he recommended the use of a concentrated solution of soda. The authors state that "arable earth, when moistened constantly, emits into the atmosphere the ammonia of the ammoniacal salts which it contains." In the opinion of M. Schlœsing the very opposite proposition is true.

Holmine (Soret's Earth X) contains at least Two Metallic Radicles.—Lecoq de Boisbaudran.—Will be inserted in full.

On Dysprosium.—Lecoq de Boisbaudran.—Will be inserted in full.

The Density of Atmospheric Air and its Components, and on the Atomic Volume of Oxygen and Nitrogen.—J. Wroblewski.—The density of oxygen at its critical point is 0·6; at −200°, under the pressure of 0·02 metre, it is 1·24. Its atomic volume is therefore 14, and not 16 as Dumas held. The density of nitrogen at its critical point is 0·44; at the moment of its solidification, 0·9. Its atomic volume is close upon 15·5. The density of liquid air at −146·6° and 45 atmospheres is 0·6.

The Combinations of Phosphoric Acid with Titanic Acid, Zirconia, and Stannic Acid.—MM. P. Hautefeuille and Margottet.—The phosphates of titanic acid, of zirconia, and of stannic acid have the atomic composition of silicium phosphate. If phosphoric acid is employed as a solvent they can only be obtained in the octahedral form, whilst silicium phosphate can be obtained not merely in this form, but in three others incompatible with the first.

Action of Vanadic Acid upon Ammoniacal Salts.—A. Ditte.—Ammoniacal salts may be divided into three groups according to their behaviour with vanadic acid. As instances of the first group the author gives ammonium phosphate, arseniate, molybdate, tungstate, iodate, and oxalate.

Studies on Butter.—E. Duclaux.—The constitution of the glycerides with volatile acids appear to be identical in all the butters examined.

Bulletin de la Société Chimique de Paris.
Vol. xlv., No. 6, March 20, 1886.

Remarks on a Memoir by M. Schuppaus entitled "On the Action of Chloriue upon Boiling Benzol." J. Meunier.—M. Schuppaus in a recent memoir confirms the experimental facts on an "Isomer of Benzol Hexachloride," published by the author (*Soc. Chim.*, 1884, p. 530), save as concerns the optical properties of the crystals of this substance. The author found that these crystals have cubic forms, and that they are isotropic. M. Schuppaus, on the contrary, maintains that they are double refractive. A new examination made with a good polarising microscope proves that this substance, when really pure, has no action upon polarised light, whilst the ordinary hexachloride presents, under the same conditions, a series of the most brilliant tints.

Action of Acetic Acid upon French Oil of Turpentine.—MM. Bouchardat and Lafont.—Acetic acid combines even in the cold with oil of turpentine, forming monoacetates belonging to two quite distinct series, terebenthenic and terpilenic, whilst the uncombined oil is transformed into two carbides, $C_{20}H_{16}$, the one monovalent, analogous to terebenthene, and the second bivalent, an active terpilene.

Syntheses of an Active Terpilenol and two Active Camphenols by means of Oil of Turpentine.—G. Bouchardat and J. Lafont.—Oil of turpentine on treatment with acetic acid yields, besides terpilene, the two series of acetates corresponding to this terpilene and to terebenthene, and the hydrates of the same formula, but equally belonging to the two isomeric series.

Origin of the Ammonia-Soda Process.—L. Mond.—From the *Journal of the Society of Chemical Industry.*

Observations on Mr. Mond's Paper concerning the Origin of the Ammonia Process.—M. Scheurer-Kestner.—A supplement to the foregoing paper.

Application of Oxycellulose to the Determination of Vanadium.—G. Witz and F. Osmond.—The authors prepare slips of calico partially converted into oxycellulose, and immerse them in baths containing a solution of the substance in which vanadium is to be detected or determined, and for comparison in other baths containing known proportions of vanadium. They are then printed with the ordinary mixture for aniline blacks, minus the hypovanadium chloride. The blacks are then developed in the oxidation chamber and compared.

Action of Acid Ammonium Oxalate upon the Solubility of the Neutral Oxalate.—R. Engel.—The quantity of one of the oxalates in solution diminishes as the other increases. If a saturated solution of neutral ammonium oxalate is treated with a little oxalic acid there is not a precipitate of the acid salt, as it is generally supposed, but of the neutral salts. If the quantity of oxalic acid is increased a mixture of both salts is deposited.

Influence of Neutral Potassium Oxalate upon the Solubility of the Acid Oxalate.—R. Engel.—The solubility in water of acid potassium oxalate can only be known approximately. If an excess of the acid oxalate is placed in water it is partially dissociated into quadroxalate, a part of which is deposited, and into neutral oxalate, which remains in solution.

Reagent for Detecting the Acid Function of Weak Acids and Congeneric Functions.—R. Engel.—Already noticed.

On Amyl Monochlor-acetate.—L. Henry.—This compound is a colourless mobile liquid having a fruity odour like that of amyl acetate. It is almost insoluble in water, to which, however, it communicates its agreeable odour. Its density at 0° is 1·063; the boiling-point under the pressure of 751·5 m.m. is 190°.

Process for the Preparation of Phosphoric Acid.—A. Joly.—The ammonia of ammonium phosphate may be easily destroyed with *aqua regia*. It is possible to diminish the quantity of ammonia to be destroyed by taking advantage of the almost complete displacement of ammonia by means of hydrochloric acid in presence of phosphoric acid, and the relative insolubility of ammonium chloride in strong hydrochloric acid.

Volatile Products of Wines and Equation of the Fermentation of Sugars by Mycoderma cerevisiæ and M. ellipsoideus.—Ch. Ordonneau.—Already noticed.

On Dioxyethyl-methylene.—L. Henry.—The author admits the priority of M. Greene, who detected and described this compound as far back as 1879.

MEETINGS FOR THE WEEK.

Monday, 24th.—Society of Arts, 8. (Cantor Lectures). "Animal Mechanics," by Dr. B. W. Richardson, F.R.S.
Tuesday, 25th.—Institution of Civil Engineers, 8. (Anniversary).
—— Royal Medical and Chirurgical, 8.30.
—— Society of Arts, 8. "Cyprus since the British Occupation," by G. Gordon Hake.
—— Royal Institution, 3. "The Function of Circulation," by Prof. Arthur Gamgee, F.R.S.
Wednesday, 26th.—Geological, 8.
Thursday, 27th.—Royal, 4.30.
—— Philosophical Club, 6.30.
—— Royal Institution, 3. "Habit as a Factor in Human Morphology," by Prof. A. Macalister, F.R.S.
Friday, 28th.—Royal Institution, 9. "Electrical Deposition of Dust and Smoke," by Prof. O. Lodge.
—— Quekett Club, 8.
Saturday, 29th.—Royal Institution, 3. "Light, with special reference to Effects resulting from its Action on various substances," by Prof. Stokes, Pres.R.S.

TENDERS FOR TAR.

The Corporation of Walsall are ready to receive Tenders from persons willing to purchase the surplus Tar made at their Old and New Gas Works during one year from the 1st July next.

The Corporation will deliver it into the Contractor's boats at the Gas Works. Not more than two boat loads will be allowed to remain in the tanks at each Gas Works at any time. The price per quantity of 210 gallons to be stated. To be paid for monthly.

Tenders, sealed and marked outside "Tender for Tar," are to be sent to me on or before Saturday, the 29th May instant.

Security will have to be given for the performance of the contract.

JOHN R. COOPER, Town Clerk.

Borough Offices, Walsall,
13th May, 1886.

ELECTROLYTIC CONDUCTION IN RELATION TO MOLECULAR COMPOSITION, VALENCY, AND THE NATURE OF CHEMICAL CHANGE:

Being an Attempt to apply a Theory of "Residual Affinity."*

By HENRY E. ARMSTRONG Ph.D., F.R.S.

(Concluded from p. 243.)

Valency—Chemical Change.

Notwithstanding the fierce controversy which has been waged between the advocates of the doctrine of fixed valency and the advocates of the doctrine of varying valency, our views on the subject are still in an unfortunate degreee unsatisfactory and indefinite. Even those—and they probably form a large majority—who regard valency as variable, dependent both upon the nature of the associated radicles and the conditions—especially as to temperature—under which these are placed, often hesitate to attribute a valency sufficiently high to account for every case of combination; in fact, both parties agree in distinguishing "atomic" from "molecular" compounds, and differ only as to where the line shall be drawn.

It is difficult to over-estimate the importance of the theory of valency: its application has led to an enormous extension of our knowledge of carbon compounds especially, and it has furnished us with a simple and consistent system of classifying the mighty host of these bodies; but, on the other hand, it may be questioned whether it has not led us away from the search into the nature of chemical change, and even if the introduction of the terms saturated and unsaturated has not had a directly pernicious effect. The almost universal disregard of molecular composition as an important factor in chemical change in the case of solids and liquids, and the popular tendency to overlook the fact that our formulæ of such bodies are purely empirical expressions, has undoubtedly exercised a prejudicial influence.

No known compounds *are saturated*—if any were, such would be incapable, I imagine, of directly taking part in any interaction, and in their case decomposition would necessarily be a precedent change. The paraffins are apparently of all bodies the most inert and the most nearly saturated, and next to them comes hydrogen—the unsaturated character of which is displayed in interactions such as occur at atmospheric temperatures between it and platinum and palladium, and when it displaces silver from silver nitrate or certain of the platinum metals from their salts. One of the most striking instances perhaps of popular error in this respect is water, which is always regarded as a saturated compound, although its entire behaviour and especially its physical properties characterise the molecule H_2O, I think, as that of an eminently unsaturated compound: I fail to see how otherwise we are to explain the high surface tension and high specific heat of liquid water, its high heat of vaporisation, and its imperfectly gaseous behaviour up to temperatures considerably above its boiling-point, let alone its great solvent power and its tendency to form hydrates with a multitude of compounds—*especially oxygenated* compounds, be it added.

The theory was brought most prominently under the notice of chemists by Helmholtz in the last Faraday lecture that electricity, like matter, is as it were atomic, and that each unit of affinity or valency in our compounds is associated with an equivalent of electricity—positive or negative; that the atoms cling to their electric charges, and that these charges cling to each other. Thus barely stated this theory does not appear to take into account the fact that the *fundamental* molecules even of so-called atomic compounds *are never saturated*, but more or less readily unite with other molecules to form molecular compounds—molecular aggregates; and unless the application of the theory to explain the existence of such compounds can be made clear, chemists must, I think, decline to accept it.* There is, however, a most significant passage in Helmholtz's paper, in which it is pointed out that (in a Daniell's cell) the phenomena are the same as if equivalents of positive and negative electricity were attracted by different atoms, and perhaps also by the different values of affinity belonging to the same atom, with different force: are we to seek for an explanation in this direction? The impression which the facts make upon the mind of the chemist certainly is, 1, that no two different atoms have equivalent affinities; and, 2, that affinity is a variable depending on the nature of the associated elements; but owing to the recognised complexity of nearly all cases of chemical change, it is difficult to draw any very definite conclusion on this point.

If, however, the nature and properties of so-called molecular compounds generally be considered, and if an attempt be made to form any conception of their constitution, one striking fact is noticeable, viz., that the *metals* in them apparently retain the properties which they exhibited in the parent atomic compounds. Every one knows the marked difference in properties of ferrous as contrasted with ferric salts: they differ not only in chemical behaviour, but also in their physical properties, and are readily distinguishable by their colour. The properties of the ferrous molecular compounds, however, are those of the simple ferrous compounds: ferrous potassium chloride, for example, $Fe_2Cl_4.Cl_2K_2$, is a green salt much like ferrous sulphate. Facts such as these have led me to suggest that in such cases the formation of the molecular compound is due to the attraction of the negative element of the one "atomic" compound by the negative element of the other, the metal having no influence except that the amount of affinity of which the negative element is possessed depends on the nature of the metal with which it is associated. It would in fact appear that hydrogen and the metals generally may be regarded as the analogues of the C_nH_{2n+1} and C_nH_{2n-7} hydrocarbon radicles, and that their compounds with negative elements may be likened to unsaturated hydrocarbons of the form—

$$C_nH_{2n+1}.CH.CH_2.$$

We know that whenever such a compound enters into combination the C_nH_{2n+1} radicle takes no part in the change, combination of whatever kind being effected by means of the unsaturated radicle $CH.CH_2$ with which it is associated. I do not mean to contend that the metals are fully neutralised in their compounds, but merely that as a rule they behave as though they were saturated just as do the C_nH_{2n-7} radicles derived from the benzenes. There can be little doubt that an absolute distinction must be drawn between hydrogen and the metals on the one hand, and the non-metals on the other. Regarding the facts in the light of our knowledge of carbon com-

* A Paper read before the Royal Society, March 25th, 1886.

* It is noteworthy that Clerk Maxwell ("Electricity and Magnetism," 1873, vol. i., p. 313), when speaking of the theory of molecular charges, says, "This theory of molecular charges—he uses the expression molecular in the sense that the chemist uses the term atomic—may serve as a method by which we may remember a good many facts about electrolysis. It is extremely improbable that when we come to understand the true nature of electrolysis we shall retain in any form the theory of molecular charges, for then we shall have obtained a secure basis on which to form a true theory of electric currents, and so become independent of these provisional theories." And later (p. 315): "While electrolysis fully establishes the close relationship between electrical phenomena and those of chemical combination, the fact that every chemical compound is not an electrolyte shows that chemical combination is a process of a higher order of complexity than any purely electrical phenomenon."

pounds, it is difficult to resist the conclusion that the differences observed are due to differences in structure of the stuffs of which the elements as we know them are composed, the which differences condition perhaps a different distribution of the electric charge or its equivalent in the case of each element.

In the earlier part of this paper I have ascribed the influence which the one set of molecules of the composite electrolyte exercise upon the other during electrolysis to the existence of "residual affinity." I believe this view also to apply to the explanation of the occurrence of chemical change. To quote the words of Arrhenius, "L'activité électrolytique se confonde avec l'activité chimique." Several pregnant examples of this have already been given by Ostwald (*Z. Pr. Chem.*, 1884, 30, 93).

The investigation of the nature of chemical change has assumed an altogether different aspect since the publication of Mr. H. B. Dixon's inquiry into the conditions of chemical change in gases (*Phil. Trans.*, 1884, 617; see also *Chem. Soc. Trans.*, 1886, 94). Mr. Dixon has clearly proved that it is impossible to explode a mixture of carbonic oxide and oxygen, and that the change—

$$2CO+O_2=2CO_2$$

is effected when sparks are passed across the tube containing the gaseous mixture *only in the path of the discharge*. If traces of water be present *explosion* takes place, the velocity of propagation of the explosive wave increasing with the amount of water up to a certain maximum. These results completely dispose of the popular explanation of such changes, viz., that the molecules in the path of the discharge undergo *dissociation*, that the dissimilar atoms thus liberated then combine together, and that as the heat developed in their union causes the dissociation of yet other molecules, change gradually extends throughout the mass.* Mr. Dixon's experiments have not only shown that the propagation of change is dependent on the presence of a third body, but that this third body must bear a certain relation to those with which it is associated: CO_2, CS_2, C_2N_2, CCl_4, SO_2, and N_2O were found by him to have no action, and only water—or bodies which formed water under the conditions of the experiment—were found capable of determining the explosion, and there is an obvious difference in constitution between water and the bodies found incapable of determining explosion: the former being a compound of a positive with a negative element, the latter being all compounds of two negative elements. If it be permissible to generalise from this single instance, it may hence be stated, that in order that interaction shall take place in cases such as that under consideration, it is not only necessary that the elements of the "catalyst" shall be *divisible*† between the interacting substances—the elements of CO_2 are obviously as divisible between CO and O_2 as are those of H_2O—but that the catalyst shall consist of a positive and a negative and not of two negative radicles. On this view, it is possible to understand that water itself may act as the catalyst in determining the formation of water at high temperatures from hydrogen and oxygen.‡

In the case discussed (the oxidation of carbon monoxide) interaction takes place at a very high temperature, and therefore—since high temperature may be regarded as the equivalent of high electromotive force—under conditions under which the catalyst water is probably a simple electrolyte. The behaviour of sulphur dioxide in presence of oxygen and water is instructive as being a case of an analogous interaction occurring at a low temperature. From a most carefully conducted series of experiments by Mr. Dixon (*Journ. of Gas Lighting*, 1881, 37, 704) it appears that not only does sulphur dioxide not undergo change in contact with dry oxygen, but that it even resists oxidation if water vapour be present, and at a temperature of 100°; as is well known, however, oxidation takes place—but only *slowly*—when an aqueous solution of sulphur dioxide is in contact with oxygen. In this case, in the gaseous mixture the water apparently is not under such conditions that it can act as a simple electrolyte or even form a composite electrolyte, and action only takes place when the conditions become such that a composite electrolyte can be formed; Ostwald's observations may be held to prove, I imagine, that a very imperfect composite electrolyte results on dissolving sulphur dioxide in water, and in accordance with this is the fact that the aqueous solution is but *slowly* oxidised.*

If a clear distinction can be drawn—as I suppose it can—between simple and composite electrolytes, the presence of a member of the latter class will probably be found to be essential to the occurrence of many interactions taking place at moderate temperatures; thus the oxidation of iron, which is generally supposed to take place only in moist air, is doubtless dependent, not merely on the presence of *water*, but of *impure* water—of water rendered conducting by association with foreign matters; similarly it may be expected that zinc will be found to have no action on water even when associated with a less positive metal, and it would doubtless have no action on sulphuric acid if such a compound were obtainable in a pure state; but a mixture of sulphuric acid and water readily dissolves it, as the two together form a composite electrolyte of comparatively low resistance.

It can scarcely be doubted that when our elements or compounds are resolved into their ultimate atoms, these atoms are capable of *directly* uniting, and that no catalyst is then required. But if this be the case, and if, as I suppose, the atoms rarely *saturate* each other, the *direct* union of compounds should also be possible in cases in which there is considerable residual affinity; such union would not involve a separation from each other of the constituent elements of one or both of the interacting bodies such as takes place in the changes previously considered. Union of two molecules having taken place, the elements of the interacting bodies having thus been brought into intimate association, it is very probable that in many cases intramolecular change will then supervene, resulting sometimes in mere atomic redistribution, at other times in the resolution of the complex molecule into simpler molecules. I am inclined to think that the majority of so-called double decompositions are thus brought about.

The union of sulphuric anhydride with water to form sulphuric acid, and of sulphuric acid with water to form hydrates, are doubtless cases of this kind. The formation of the hydrate $SO_3.OH_2$ must be supposed to be immediately followed by the occurrence of atomic redistribution if we accept the current view that sulphuric acid is a hydroxide of the formula $SO_2(OH)_2$; whether after the formation of the hydrate $H_2SO_4.OH_2$ has taken place atomic redistribution in like manner supervenes is a moot point; the large amount of heat developed by the interaction of water and sulphuric acid is, however, specially noteworthy.

Sodium hydroxide is universally regarded as the analogue of water: is its action on sulphuric acid analogous

* I am not to be understood to imply that dissociation does not take place in the path of the discharge; on the contrary, for all the facts appear to me to indicate that conduction and electrolysis are inseparable phenomena in gases as in liquids (comp. Schuster, *Proc. Roy. Soc.*, 1884, 317).

† Mr. Dixon's experiments appear to prove that during the interaction of carbonic oxide and oxygen in presence of water an actual division of the elements of the water molecules takes place between the carbonic oxide and oxygen molecules, and hence that the water does not exercise a mere contact action.

‡ When this question first came under discussion at the Chemical Society I said that I looked forward to the time when probably it would be found that a mixture of pure hydrogen and oxygen was inexplosive, like one of pure carbonic oxide and oxygen. I was then still under the influence of current opinion and regarded water as a saturated compound, and had not yet realised the important function of "residual affinity" in such changes.

* The behaviour here described of sulphur dioxide appears to me to furnish another argument adverse to the dissociation hypothesis, as oxidation takes place under the conditions least favourable to the occurrence of dissociation.

to that of water? I certainly am inclined to hold that it is, and that in the first instance an aggregate,—

$$NaHO.SO_4H_2,$$

results, owing to the attraction of the oxygen of the hydroxide by the oxygenated radicle of the acid: atomic redistribution thereupon takes place, and either the molecule is resolved into two others, water and sodium hydrogen sulphate, or a new compound is formed which is easily resolvable into these latter. Moreover, I am inclined to attribute this change and the consequent displacement of the hydrogen in the acid by the sodium, not to the fact that sodium has a greater affinity than hydrogen has for SO_4, but to the tendency of hydrogen to displace the sodium in sodium hydroxide and to form water. I do not contend that in such a case as that quoted direct interaction will take place between the substances as we know them in the solid state; these may consist of comparatively inert complex aggregates which require to be resolved into simpler molecules either by dissolution or by application of heat. In other words, the presence of water may be necessary, not because it is essential to have an electrolyte present, but because the occurrence of both molecular interaction and electrolytic conduction depends on identical molecular and intermolecular conditions. The chemical interaction takes place entirely independently of the water molecules, and these latter serve only to separate and keep apart the fundamental molecules of which the interacting bodies are composed.

No final decision for or against the view here put forward can well be arrived at except by the study of the behaviour of gaseous bodies such as ammonia and hydrogen chloride, for example; if proof can be given that these compounds are capable of directly uniting without the intervention of any third body, a most important step will have been made.

Other cases deserving of study are the conversion of nitric oxide into nitric peroxide, oxidation by means of ozone, and the action of metals such as sodium on water. As the formation of nitric peroxide involves the prior separation of oxygen-atoms from oxygen-atoms, and not merely the combination of two molecules, it is not improbable that interaction between nitric oxide and oxygen molecules will only take place in the presence of a catalyst. But it is to be borne in mind that both nitric oxide and ozone are bodies which are capable of interacting with molecules of their own kind, and that considerable heat is thereby developed; and it is conceivable that such bodies being possessed of high residual affinity may directly enter into combination with others which have but little residual affinity. As regards the action of sodium on water, the difference in behaviour with dilute sulphuric acid between moderately pure zinc and very nearly pure zinc is so marked that the vigorous action between sodium and water cannot be held to prove much, as no special care is ever taken to prepare sodium pure; the question whether the affinity of the oxygen in water for sodium is sufficient to cause their direct association and consequent interaction is an interesting one for experimental inquiry, although it would be very difficult to make the experiment properly.

One other application of the theory dwelt on in this paper remains to be mentioned. It is now well established that on exploding gaseous mixtures within a closed chamber the maximum theoretical temperature is never reached; and this has hitherto always been explained as due to the occurrence of dissociation, whereby the change is retarded. If in a mixture say, of carbonic oxide, oxygen, and water gases the three kinds of molecules act together in the manner I have supposed, it is probable that the extent to which they mutually influence each other would vary with the temperature, and that it would tend to diminish above a certain temperature; if such were the case, change would be retarded in the manner in which it appears to be in explosions within closed chambers. Dissociation undoubtedly does take place in many cases, but there is now a considerable amount of evidence on record to show that the bounding surfaces exercise a most important influence; this is usually not sufficiently taken into account.

RESEARCHES ON THE VITALITY OF THE SPORES OF PARASITIC FUNGI, AND THE ANTISEPTIC PROPERTIES OF FERROUS SULPHATE.*

By Dr. A. B. GRIFFITHS, F.R.S. (Edin.), F.C.S. (Lond. and Par.)[1]
Lecturer on Chemistry, Technical School, Manchester,
Examiner in Chemistry, Blairlodge School, Polmont, N.B., &c.

FERMENTS and microscopic fungi are certainly inconspicuous organisms, but they cause us an untold and untellable amount of trouble, vexation, and loss, not to mention the pain, misery, and death which these low forms of life produce when they find entrance into the system either of an animal or man himself. Their small dimensions, their invisibly minute organs, their ever-present germs floating about in the air and carried in the water until they find surrounding circumstances and a suitable medium in which they can live their life-histories —all combine to render us helpless to a certain extent in our strife and struggle with them.

I have already had the honour of presenting to the Royal Society of Edinburgh a paper "On the Antiseptic Properties of Salicylic Acid,"† on the "disease ferments" which produce after changes in saccharine liquors, like beers, wines, &c. In this paper I wish to detail some researches on the use of iron sulphate as an antiseptic agent in connection with parasitic fungi which attack our crops; also the length of time spores of fungi are capable of existing in a dry state in the atmosphere.

It will be remembered that I have advocated the use of iron sulphate as a manure for some four or five years. My memoirs on the subject are to be found in the *Journal of the Chemical Society* and the CHEMICAL NEWS (1882-6). These investigations have also been repeated by others with similar results.‡ But, beyond being simply a plant-food, iron sulphate has antiseptic properties which I have already shown is sufficient to destroy certain low forms of plant-life (CHEMICAL NEWS, vol. xlix., p. 279 [1884], and *Journal of the Chemical Society*, 1886, p. 119), yet at the same time largely increasing the yield of agricultural crops generally.

Concerning the vitality of certain spores of fungi, I have experimented in the following manner:—A quantity of spores of *Peronospora infestans* (potato-disease) were taken from a crop of diseased potatoes. These spores were then placed in a porcelain mortar along with about 5 grms. of a mixture of calcium sulphate and calcium carbonate, which were thoroughly mixed together. This mixture was then placed in a small oven always kept at a temperature of 35° C. (dry heat). After the spores had been dried up with these mineral substances (which principally constitute the dust found in the atmosphere) for two months, they had not lost their vitality, for in the space of three days after "sowing" they began to penetrate into the mesophyll of the leaves (of a potato plant) through the stomata. The leaves of *Solanum tuberosum*, along with dried two-months' old spores of *Peronospora*, were kept in a warm moist atmosphere, such conditions being favourable for the development of these spores. On

---

* Read before the Royal Society of Edinburgh May 17th, 1886.

† CHEMICAL NEWS, vol. liii., p. 28; *Chem. Soc. Journ.*, 1886, p. 386; and *Proc. R. S. E.*, No. 121.

‡ See Dr. Munro's paper, CHEMICAL NEWS, vol. liii., pp. 2 and 3; also *Journal of the Chemical Society*, 1886, p. 389.

the fifth day after "sowing" there was a mycelium which had ramified through the tissues of the leaf, and I also observed the production of conidia-bearing branches making their appearance through the stomata of the leaves. After *six* months of dry heat another portion of the dust was examined under the microscope, mounted in water as before. The cellulose wall of the spores appeared rather shrivelled. Their vitality had not disappeared, for after seven days from "sowing" on the potato-leaf there was a rapid development of hyphæ, mycelium, &c.; thus showing that, even after the spores had been dried up for six months as dust, they were capable of germinating, and each organism leaving its life-history upon the host plant.

Again, after being in a dried state for ten months, it was found that the spores had lost their vitality. They did not germinate upon the leaves of *Solanum*, not after being in contact with the leaves in a damp and warm atmosphere for a month or six weeks. Under the microscope the spores were seen to be shrivelled up and their protoplasm dead.

From this investigation it will be seen that the spores of *Peranospora infestans* may be dried up in an atmosphere and preserved as dust for the space of eight months without the loss of their vitality, and will germinate again when favourable circumstances are offered for their development.

The next point we come to is a study of the action of a solution of iron sulphate ($FeSO_4$) upon certain parasitic fungi. An aqueous solution containing as little as 0·1 grm. of iron sulphate in 100 grms. of water was found to have the power of destroying the *Peronospora infestans* (potato-disease). I cultivated a good crop of *Peronospora* on the cut surface of the tubers of diseased potatoes, in a warm damp atmosphere, under a bell-glass. Also the leaves of *Solanum tuberosum* were placed under the same bell-glass. The spores of the fungus easily threw out hyphæ which penetrated the tissues of the leaves. By taking a portion of the fungus and its spores (conidia) by the point of a needle, and placing them upon a microscopic slide, mounting them in a drop of water, then running in between the slide and cover-slip the above-named solution of iron sulphate, it was observed that the cellulose wall of the hyphæ and of the spores of *Peronospora* were perforated in all directions.

It appears that iron sulphate acts upon the cellulose, or the form of cellulose, making up the external wall of this lowly organism and its spores.

Iodine and sulphuric acid do *not* colour the cellulose walls of this fungus a blue colour, whereas it is a well-known fact that the cellulose of the higher plants is coloured by iodine and sulphuric acid.

I have also found that the iron sulphate solution does *not* attack the cellulose wall of the higher forms of plant-life, nor even when we get so low in the scale as the Zygnemaceæ (fresh-water Algæ), for the iron sulphate solution made no impression upon the cellulose walls of *Spirogyra*.

It is most probable that the cellulose of parasitic fungi is different in its atomic structure from the cellulose of the higher plants. It is most likely an isomeric modification of ordinary cellulose.

In passing I may state that Dr. H. Müller (*Biedermann's Centralblatt für Agricultur-Chemie*, 1883, pp. 630 to 637) recommends the use of a solution of iron sulphate (1 part of $FeSO_4$ in 2 parts of water) for washing vines, as an antiseptic against the vine-mildew. No doubt the action of iron sulphate upon the vine-mildew is the same as I have already described concerning *Peronospora infestans*.

I have found that lactic acid is always formed in small quantities in diseased potato-crops; not only in the tubers, but in the leaves of the potato-plant during life. It may be that during a damp warm summer, which is always favourable for the development and growth of parasitic fungi, that a portion of the starch in the tubers of the potato-plant becomes hydrated,—that is, converted into one of the members of the glucose family of carbohydrates, this glucose being most likely decomposed by the growth of *Peronospora* into lactic acid:—

$$C_6H_{12}O_6 = 2C_3H_6O_3.$$

Concerning the lactic acid found in the leaves of *Solanum tuberosum* during disease, we know, from the researches of Sachs and others, that starch is one of the first products of assimilation in the chlorophyll cells. This starch is subsequently transferred to other cells by the process of metastasis; but before it is transferred it is converted from the insoluble (starch) to a soluble form,—viz., glucose sugar,—which may account for the presence of lactic acid in diseased leaves of *Solanum*, as described above.

It has been ascertained by the veteran chemist M. Chevreul (Hon. F.R.S.E.) that fungi (like the mushroom) *greatly flourish* when watered with a weak solution of potassium nitrate. From this fact the question may be raised, How far have *potash* manures in damp seasons helped to foster the development and growth of parasitic fungi? At any rate the true potato-disease appeared about the year 1830, and this was about the time artificial manures were first applied to our lands, for it was found that farm-yard manure was incapable of returning all the mineral constituents to the soil which had been extracted by the growing crops. This fact was well established by the experimental investigations of Schubert, Saussaure, and particularly to the researches and philosophy of Liebig.*

Concerning the potato-plant it appears, from De Candolle, that it is a native of Chili, was first introduced into Europe by the Spaniards† about 1580, and a little later into England. For nearly 250 years no signs of disease appeared in the crops of cultivated potatoes. Hence it may be that *potash* manures have rather aided the development and growth of the *Peronospora infestans*, in damp warm seasons, than otherwise. I am fully aware that M. Déhérain has shown that in certain plants starch is *not* generated by chlorophyll unless *potash* is in the soil. (If potash salts are added, then starch begins to be formed in the chlorophyll granules). Potash manures appear to be not only one of the necessary mineral foods of *Solanum tuberosum*, but also for its parasitic fungus.

No doubt the potato fungus existed centuries ago on the wild potato-plants of South America. On the introduction of the plant into Europe the circumstances and surroundings (as far as climatic conditions are concerned) were changed, not only for the potato-plant itself, but also for its parasite. Hence it may be that, on the introduction of potash manures, these plant-foods revived the dormant vitality of *Peronospora infestans* to its natural activity, giving rise to the frightful ravages which this fungus produced in our potato-crops from fifty or sixty years ago, and have never since entirely disappeared.

As we have seen, the spores of *Peronospora* are capable of being dried up with dust for a considerable time without losing their vitality (the same remark applies to the spores of wheat-mildew and other fungoid growths). I recommend the use of a weak solution of iron sulphate to water ordinary farm-yard manure before it is applied to the land. Farm-yard manure may contain spores from the wheat-straw, &c., forming the litter in the farm-yard. These and other spores hybernate until the Spring (farm-yard manure being a medium that rather favours this dormant state than otherwise), and are then ready to live their life-history again, the infested farm-yard manure being a material which is capable of inoculating the cultivator's newly set seed-potatoes, &c. Again, it may be that the seeds (wheat for instance) contain these minute spores of disease which are always more or less in the atmosphere during the summer months. The farmer has

* "The fertility of a soil cannot remain unimpaired unless we replace in it all those substances of which it has been thus deprived." —(Liebig's "Organic Chemistry in its Application to Agriculture and Physiology," p. 174.)

† See Clos' "Quelques Documents sur l'Histoire de la Pomme de Terre," *Journal d'Agric. Pratiq. du Midi de la France*, 1874.

a remedy, namely, by steeping his seeds before "setting" in a solution of ferrous sulphate, for the spores are all destroyed by this mineral substance, and the seed is not injured in the least.

We now come to consider the action of iron sulphate upon another parasitic fungus, namely, the "wheat-mildew," in both stages of its life-history. First, with the red spores ("rust") of the barberry fungus, which produce hyphæ and a mycelium in the cells of the stem or leaf of a wheat-plant or similar cereals, and also with the two-celled spore (teleutospores) of the wheat-mildew, which germinate on the leaf of the barberry. I have *not* ascertained to what length of time the two kinds of spores of this dimorphic fungus are capable of retaining their vitality or power of "germination." At any rate it may be as long as that of *Peronospora infestans*.

On placing the *Œcidium* spores, uredospores, and teleutospores on slides under the microscope (mounted in water), and on running in between the cover-slips the solution of iron sulphate (0·1 grm. in 100 grms. of water), the different kinds of spores are completely destroyed. Not only the spores, but the hyphæ which give rise to mycelia within the stem and leaves of *Triticum vulgare* (wheat-plant), are completely destroyed, the cellulose walls being perforated by this antiseptic agent, while the cellulose walls of the epidermis of the wheat-plant (through which teleutospores and uredospores make their appearance) are not "touched" in the least by this solution.

In diseased wheat-crops I have found small quantities of alcohol, and also acids, but not in healthy crops. These bodies may be due to the decomposition of glucose sugar, which is always in the sap of the cells. Hence it appears that parasitic fungi may cause the abnormal development of compounds within the living cells of the host plant, and so poison its various parts. I have obtained, on watering healthy potato-plants (roots, and also the leaves) with a solution of *lactic acid*, shrivelled leaves and "brown spots," something like the appearance when the plant is infested by *Peronospora*. I am inclined to think that the poisonous products formed by *Peronospora* are the immediate cause of the unhealthy condition of potato-crops at certain times. The same remark applies to other parasitic fungi which attack our crops.

My friend Mr. G. W. Edgson, of Etton, Peterborough (an agriculturist of great experience), has found that wheat-crops manured with iron sulphate completely resist the attacks of wheat-mildew (*Chemical Society Journal, Trans.*, 1886, p. 116).

Hence it will be seen that iron sulphate is a valuable agent in the hands of the agriculturist, not only as a manure, but as a remedy against the attacks of that "unseen mist of organic forms."

It will also be observed that the solution of iron sulphate used in my microscopical studies perforates the cellulose walls of the cell of parasitic fungi, and not the cellulose walls of the higher plants. This points to a constitutional difference in the atomic structure of this form of cellulose,—that is, it is an isomer of ordinary cellulose.

I may allude, in passing, that (to a certain extent) a difference was observed in the structure of fungi from the higher forms of plant-life by the father of physiological botany, Dr. Grew, F.R.S., two hundred years ago, for he says*—"*Both the substance of the pipes and the other parts of the mushroon, so far as visible, is answerable only to the cortical or pithy part of a plant,—so that it seems to be but half of a perfect plant.*"

In conclusion, the "Golden Age," which Ovid speaks about in his "Metamorphosis" (Liber I.),—

> "Mox etiam fruges tellus inarata ferebat,
> Nec renovatus ager gravidis canebat aristis,"

has long passed away. The virgin soils of centuries ago have been used up, and new discoveries, which help the fertility of the soil and place in man's hand the means of destroying parasitic disease, are of national importance, especially to a country like our own, where there is great competition with foreign nations in agricultural produce: for this reason I tender my little mites of scientific work for the good of humanity.

I wish here to thank my friends (personal and scientific):—Sir Richard Owen, K.C.B., F.R.S.; Sir J. B. Lawes, Bart., F.R.S.; Prof. J. P. Cooke, LL.D. (Harvard University, U.S.A.); Prof. F. Guthrie, F.R.S.; Dr. A. C. Maybury, D.Sc., M.R.C.S; Dr. G. McGowan, F.R.S.E.; Mr. Johnstone (of Geneva); Mr. J. C. Wright, F.C.S. (of Ayr), and others, for their kind letters and suggestions concerning my agricultural researches.

PROCEEDINGS OF SOCIETIES.

CHEMICAL SOCIETY.

Thursday, May 20th, 1886.

Dr. HUGO MÜLLER, F.R.S., President, in the Chair.

CERTIFICATES were read for the first time in favour of Messrs Thomas Akitt, 25, Gascoyne Road, South Hackney, London; Alfred C. A. W. H. Chapman, 2, Queen Anne's Avenue, High Road, South Tottenham; Charles Alexr. Kohn, Redcliffe Villa, Redcliffe Road, Nottingham; John Temple Leon, 26, Belsize Park Gardens, N.W.; William Ray, Spenceley House, Victoria Road, Leeds; William Richards, 185, Isledon Road, Finsbury Park, London, N.; Joseph Price Remington, 1233, Walnut Street, Philadelphia, U.S.; William Saunders, London, Ontario, Canada; Charles A. Smith, The Laboratory, 8, Loftus Street, Sydney.

The following were duly elected Fellows of the Society:—Messrs. Edward Jennings Ball, Ph.D., Holland Crompton, Parvati Nath Datta, Robert Elliott Doran, Richard Dormer, Witham Dobinson Halliburton, George William Saul Howson, John Tysilio Johnson, A. Wentworth Jones, William Henry Pendlebury, William Selby Simpson, Henry H. Walker.

The PRESIDENT exhibited a specimen of the mineral Argyrodite—a sulphogermaniate of silver; also a number of specimens which he had recently received from Prof. Winkler of the new element Germanium and its derivatives. He said that, according to the information given to him, germanium was a silver-white, brittle, volatile metalloid of the relative density 5·46; its atomic weight is 72·75. It appears to be identical with Mendelejeff's *Ekasilicium*, for which the atomic weight predicted was 72 and the relative density 5·5. Germanium forms two sulphides—a yellow monosulphide, soluble in alkali, which readily volatilises, subliming in well-formed crystals somewhat like those of iodine in colour; and a white disulphide. It furnishes corresponding oxides: a liquid tetrachloride, boiling at 88°; and an orange-red, crystalline, volatile tetriodide.

With reference to the President's communication on the new element Germanium, discovered by Prof. Winkler, Mr. JOHN A. R. NEWLANDS begged leave to remind the Society that, in a paper in the CHEMICAL NEWS for July 30th, 1864, nearly twenty-two years ago, he had pointed out that an element was missing in the group comprising carbon, silicon, titanium, and tin, having an atomic weight of 73, being the same element which M. Mendelejeff had several years later predicted under the name of Ekasilicium.

The PRESIDENT remarked that they all knew that Mr. Newlands had done valuable work in the initiation of the Periodic Law, and he was fully justified in calling attention to the facts of the case on the present occasion.

Dr. SPRENGEL exhibited a series of specimens illustrating the effect produced on leaden cylinders by the explosion of equal weights (15 grms.) of nitroglycerine and of mixtures of half nitric peroxide and half (*a*) CS_2, (*b*) benzene, (*c*) nitrobenzene, (*d*) nitrotoluene. The effect produced by the nitroglycerine was very much less marked than that produced by any of the other explosives, of which those containing nitrobenzene and nitrotoluene were by far the most powerful.

The following papers were read :—

46. "*Sources of Error in the Calorimetric Study of Salts.*" By Prof. W. A. TILDEN, F.R.S.

Mr. Pickering has recently published, in the *Transactions of the Chemical Society*, a paper containing very numerous estimations of the heat of dissolution of various salts at temperatures ranging from near zero to about 25° C., and in the *Phil. Mag.* for March and April he has given an account of the precautions he has taken to avoid experimental error, or to make allowance for it.

In his principal paper (*Chem. Soc. Trans.*, May, 1886) he arrives at such extraordinary conclusions in regard to the behaviour of salts in act of dissolution in water, and at the same time protests so emphatically against the suspicion that the irregularities he has observed are due to experimental error, that, having been myself occupied with experiments in the same direction, I have been led to examine Mr. Pickering's paper very carefully.

The process of dissolving a solid in water in such a manner as to allow of the determination of the heat evolved or absorbed is one which is beset with difficulties. But these are not all of equal importance, some being so small as to produce little or no appreciable effect on the result; others, however, being of such a formidable character as to render such determinations extremely difficult and uncertain. Mr. Pickering claims that his results exhibit an extremely high and altogether exceptional degree of accuracy. Without this exceptional accuracy the conclusion which he deduces cannot be maintained. A critical examination of the numbers recorded in his tables of results shows that his experiments, though undoubtedly conducted with great care and skill, have not led to results of any very unusual accuracy, and in fact that there are in many cases great discrepancies in the results of duplicate experiments. Some of these discrepancies I attribute to a want of discrimination between the several sources of error in respect to their influence on the result.

Mr. Pickering has given great attention to the calibration and observation of his thermometers, even using instruments said to be capable of reading to 1-3000th of a degree C., but he has given no detailed account of his method of correcting for the cooling or heating by radiation or conduction of the calorimeter during the progress of the experiment, although this latter, as he admits, is by far the most serious source of error, and might lead to a difference a hundred times greater than that arising from ordinary errors in calibration or reading of thermometers. Again, it would doubtless be impossible in such experiments to ensure the accomplishment of the act of dissolution in the several experiments at any given temperature in equal times; and yet if this is not done an error is introduced which it is impossible to estimate by observation of the rate of cooling before or after the experiment.

However, it is not suggested that Mr. Pickering's results are less than usually accurate, but only that they do not reach that unassailable standard which alone would justify the conclusions he draws from them. The supposition that the heat of dissolution of a given salt in water at successively higher temperatures is represented by a succession of irregular curves is not supported by Mr. Pickering's own experimental numbers, but results from the unjustifiable employment of arithmetical means. When *all* the numbers given in the tables are plotted on curve paper the remarkable sinuosities pointed out by Mr. Pickering for the most part disappear. One does perceive, however, that the discrepancies among the individual results are so great as to preclude the possibility of drawing from them any conclusion whatever as to the exact form of the curve in the several cases.

DISCUSSION.

Mr. PICKERING said that no one could be more fully aware than he was himself that the irregularities which he had observed depended on differences but little larger than those due to experimental error. The whole difficulty of the investigation lay in this very fact. No one could have laboured more energetically than he himself had done to disprove these irregularities, and he only accepted them when their existence became undeniable. In his opinion it was distinctly a case in which the means from a large number of experiments, and not each individual determination should be considered. Taking the instances selected by Dr. Tilden, he contended that the irregularities could not be regarded as experimental error. In the case of potassium sulphate the heat of dissolution from 26·5° to 17° is represented by a straight line; from 11° down to 3° it is represented by another line at a different inclination from the first, but scarcely less straight. If the point at 14° is to lie in the first line the heat of dissolution there would be 6870 cals., if in the second line 6820 cals. Now of the eight determinations on which the observed depression at this point was based, the lowest was only 6908 cals.; the mean of four determinations with one thermometer gave 6941 cals., and of four other determinations with another thermometer 6963. By no possibility could Dr. Tilden manipulate those numbers so as to lower them even to 6870, and thus obliterate the depression which they represent. The only other means by which this could be done would be to admit an error of at least 82 cals. in the general results of all the other experiments—70 in number—at the other temperatures; a proposition quite inadmissible. Mr. Pickering professed himself ready to discuss in the same way the irregularities in any of the other curves. Dr. Tilden had specially alluded to the depression in the curve of $CuK_2(SO_4)_2{\cdot}6H_2O$, which was the one salt least fully examined of all: as Mr. Pickering had mentioned in his paper (p. 282), he would have paid but little attention to this depression were it not that there was subsidiary evidence that the point at which it occurs (14°) was a temperature at which the salt experienced some marked alteration. Looking at the curve representing the heat of combination of the salt with its water of crystallisation, it would be seen that this heat is represented by a straight line from 2° to 12° showing the rapid increase of 130 cals. per degree, while from 16° to 23° the heat of combination remains constant.

On the strength of there being but one determination with K_2SO_4 at 12·36, Dr. TILDEN accused him of having repeated experiments at the debatable points without having examined the points in its vicinity. This charge Mr. Pickering entirely denied. In the case in point Dr. Tilden would find, on a more careful examination, that within about 3° of the temperature where the depression was noticed (14°, there being eight experiments here) he had made no less than nineteen determinations. Again, the lowest point (13·14°) in the $MgSO_4{\cdot}7H_2O$ curve, at which there were seven determinations, was accompanied by nine determinations at other temperatures within 1·5° of it. It was certainly natural, and indeed indispensable, that any point at which an anomaly was noticed should be more fully examined than other normal points, but the repetition of such experiments was generally accompanied by the repetition of other experiments at points above and below it, though not *necessarily* very near to it; and as a further precaution these experiments at different temperatures were in many cases, and at the expense of immense labour, performed on the same day (p. 281).

Dr. TILDEN suggested that Mr. Pickering, while fully alive to the less important errors introduced by defects in the thermometers, might have overlooked the greater errors involved in determining the rate of cooling, and in

the manipulation generally. Dr. Tilden would, however, find that in a paper read before the Physical Society (*Phil. Mag.*, 1886, p. 324) he had discussed not the errors inherent in thermometers, as he did in two other papers (*ibid.*, 180, 330), but the errors of calorimetric work as illustrated by the actual results obtained in these very experiments themselves, results which had been influenced by, and would therefore afford a criterion of, the accumulated errors from all sources.

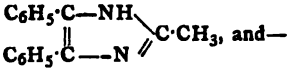
Mr. PICKERING then described his method of operation, and explained that the determination of the rate of cooling was far more simple in his experiments than those of Dr. Tilden; for the temperature of the air is always the same as that of the calorimeter, and the rate of cooling was thus reduced so far as to be constant for the whole duration of the experiment. Mr. Pickering had found that even where the dissolution of a salt was not completed within five minutes or more, the final temperature of the calorimetric water was practically attained within about half a minute: it was during this short space of one half minute only that the temperature, and therefore the cooling correction, was uncertain.

Dr. WRIGHT remarked that, according to his experience, the experimental error was much greater if the substances to be mixed were at the temperature of the air; the error due to radiation was much less if the temperature initially was as much below as it was finally above atmospheric temperature.

Prof. TILDEN, in reply, said that he thought that Mr. Pickering had failed to explain the discrepancies which he had pointed out.

47. "*On the Action of Aldehydes and Ammonia on Benzil.*" By FRANCIS R. JAPP, F.R.S., and W. PALMER WYNNE, B.Sc.

The compounds obtained with acetaldehyde and isovaleraldehyde are the glyoxalines—



Methyldiphenylglyoxaline (m. p. 235°).

Isobutyldiphenylglyoxaline (m. p. 223°).

With cinnamaldehyde, benzil, and ammonia two reactions occur, two distinct compounds being formed, one of which is practically insoluble, the other moderately soluble, in boiling alcohol. The insoluble compound has the formula $C_{32}H_{28}N_2O_2$, and is an analogue of that obtained by Japp and Hooker from salicylaldehyde, benzil, and ammonia. It has the constitution—

Dibenzoyldicinnylenediamine (m. p. 264°).

Heated with a solution of potash in methyl alcohol, it yields benzoic acid and the compound—

Benzenyldicinnylenediamine (m. p. 207°).

The soluble compound melts at 188°. It has the formula—

$$C_{37}H_{30}N_2O_3 = 2C_{14}H_{10}O_2 + C_9H_8O + 2NH_3 - H_2O.$$

As this compound may be regarded as imabenzil in the formation of which 1 mol. of cinnamaldehyde has taken the place of 1 mol. of benzaldehyde, it is proposed to name it *cinnimabenzil*.

This is the fourth of the distinct reactions in which diketones, aldehydes, and ammonia react jointly to form condensation products (comp. *Proc. Chem. Soc.*, 1884, *Trans.*, 672).

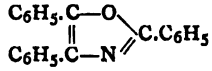
By treatment in the cold with a solution of potash in methyl alcohol, the compound $C_{37}H_{30}N_2O_3$ is decomposed into benzoate and the compound $C_{30}H_{26}N_2O_2$ (m. p. 283°).

48. "*On Imabenzil.*" By the same.

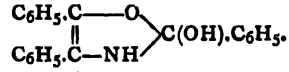
In repeating the work of Laurent on the action of ammonia upon benzil, Henius arrived at the conclusion that the three compounds described by Laurent possessed the following formulæ:—

Imabenzil	..	$C_{42}H_{32}N_2O_4$.
Benzilimide	..	$C_{42}H_{32}N_2O_4$.
Benzilam	..	$C_{42}H_{32}N_2O_2$.

In a preliminary note on the same subject (*Ber.*, xvi., 2636), Dr. Japp showed that benzilam has the formula $C_{21}H_{15}NO$, and that benzilimide, from which it may be obtained by the abstraction of the elements of water, is $C_{21}H_{17}NO_2$. He ascribed to these compounds the constitution—



Benzilam.



Benzilimide.

These formulæ have since been accepted by Henius (*Annalen*, ccxxviii., 339).

In the note above referred to, Dr. Japp further admitted that the formula assigned by Henius to imabenzil was probably correct, basing this opinion upon an examination of *amorphous* imabenzil prepared by the method of Henius.

The authors have now prepared *crystallised* imabenzil, and have been able to rectify its formula, which they find to be $C_{35}H_{28}N_2O_3$. It is formed from benzil and ammonia according to the equation—

$$3C_{14}H_{10}O_2 + 2NH_3 = C_{35}H_{28}N_2O_3 + C_6H_5.COOH + H_2O.$$

Imabenzil as prepared by Henius contains unaltered benzil. Contrary to the statement of Henius, imabenzil can be readily recrystallised; methyl alcohol was found to give the best results. The crystals have been measured by Mr. L. Fletcher, and found to agree with the description and approximate figure given by Laurent. The melting-point was found at 194°.

49. "*On Ammonia-derivatives of Benzoïn.*" By FRANCIS R. JAPP, F.R.S., and W. H. WILSON, Ph.D.

The action of alcoholic ammonia upon benzoïn was studied by Laurent and later by Erdmann. Both these chemists obtained a substance of the formula $C_{28}H_{24}N_2O$, to which Laurent gave the name *benzoïnam*. Erdmann further isolated a substance which he called *benzoïnimide*, assigning to it the formula $C_{14}H_{11}N$.

The authors confirm the formula of Laurent and Erdmann for benzoïnam. Their analyses of benzoïnimide, however, lead to the formula $C_{28}H_{20}N_2$. They regard it as an analogue of diphenanthrylene-azotide, $C_{28}H_{16}N_2$, and as it can no longer be classed as an imide they propose to call it *ditolane-azotide*. It is most readily obtained free from the other compounds formed from benzoïn and ammonia, by heating benzoïn with fused ammonium acetate over a flame until the whole of the ammonium salt is volatilised.

A third compound, not described by the foregoing investigators, was obtained. It is formed in largest quantity when benzoïn is allowed to stand with alcoholic ammonia for several weeks in the cold. It crystallises from alcohol in minute oblique tables or prisms melting at 199°. The analyses agreed best with the formula $C_{28}H_{23}NO_2$. The equation for its formation would be $2C_{14}H_{12}O_2 + NH_3 = C_{28}H_{23}NO_2 + 2H_2O$. As nothing is known concerning its constitution, it may be named, for the sake of distinction, *benzoïnidam*.

50. "*On Compounds from Benzil and Benzoïn and Alcohols.*" By FRANCIS R. JAPP, F.R.S., and JULIUS RASCHEN.

The authors have made experiments to ascertain whether other alcohols besides ethyl alcohol form condensation compounds with benzil in presence of a small quantity of caustic potash in the cold (comp. *Trans.*, 1885, 90). Of the various alcohols employed only isopropyl alcohol yielded a result. A compound of the formula $C_{31}H_{28}O_4$ was obtained, which is deposited from alcohol in small lustrous faintly yellow crystals, of rhombohedral habit, melting at 147° to 148°. The benzil and isopropyl alcohol react according to the equation—

$$2C_{14}H_{10}O_2+C_3H_8O=C_{31}H_{28}O_4+O,$$

and the compound is therefore formed by a process of reduction, and is not analogous to the compound $C_{30}H_{24}O_4$, which, as was shown by Owens and Japp (*loc. cit.*), is formed from ethyl alcohol and benzil merely by elimination of water.

The action of a small quantity of potash at ordinary temperatures upon benzoïn dissolved in various alcohols was also tried, but only in the case of ethyl alcohol was a definite result obtained. Air must be carefully excluded during the reaction, otherwise the benzoïn is oxidised to benzil. Benzoïn slowly reacts with ethyl alcohol in presence of a small quantity of potash,—

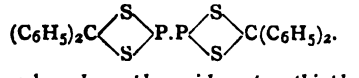
$$3C_{14}H_{12}O_2+2C_2H_6O=C_{46}H_{40}O_4+4H_2O,$$

the compound $C_{46}H_{40}O_4$ thus obtained corresponds with the compound $C_{46}H_{34}O_4$ formed by the interaction of the same molecular proportions of benzil and ethyl alcohol (*loc. cit.*). The benzoin compound $C_{46}H_{40}O_4$ melts at 249 to 250°.

51. "*On the Action of Phosphoric Sulphide on Benzophenone.*" By the same.

By heating benzophenone with phosphoric sulphide for two days at 100° the authors obtained a compound $C_{26}H_{22}S_2$, melting at 152°, previously described by Engler, who prepared it both by the action of alkaline hydrosulphides upon benzophenonidene dichloride, $(C_6H_5)CCl_2$, and by heating benzhydrol with phosphoric sulphide.

At a temperature of 140° to 150° benzophenone and phosphoric sulphide yielded a compound of the formula $C_{26}H_{20}P_2S_5$. It crystallised from hot benzene in colourless microscopic plates melting at 226° to 227°. It decomposes in melting, assuming a deep-blue colour. It may be regarded as an ethereal thio-salt formed by the union of 2 mols. of thiobenzophenone, $(C_6H_5)_2CS$, with 1 mol. of phosphorus sulphide, P_2S_3. Its constitution may be expressed by the formala—



It would thus be a *benzophenonidene pyrothiophosphite.*

On oxidation with a solution of chromic anhydride in glacial acetic acid it yields benzophenone.

52. "*The Separation and Estimation of Zirconium by Means of Hydrogen Peroxide.*" By G. H. BAILEY, D.Sc., Ph.D.

The author has determined zirconium by means of hydrogen peroxide in a number of mixtures containing also iron, titanium, and niobium, and finds that even when the zirconium forms only 2·3 per cent of the mixture, the method of separation which he has previously described (*Trans.*, 1886, 149) is applicable, and the results obtained are accurate. The zirconia precipitated in presence of a large excess of iron or of titanium does not contain a trace of these elements. The oxide generally obtained by means of hydrogen peroxide is the pentoxide, but he has also obtained a higher oxide, ZrO_3, apparently identical with that described by Cléve.

The dried oxides have a composition approximating to $Zr_2O_5.4H_2O$ and $ZrO_3.5H_2O$, though oxygen is lost at 100°, and the product remaining is not definite in composition. Dried at 15°, however, the higher oxide retains the whole of its oxygen, and is evidently more stable than the pentoxide.

Dilute mineral acids and acetic acid, which dissolves freshly precipitated zirconia quite readily, fail to act on these oxides except on prolonged heating.

53. "*An Apparatus for the Determination of the Temperature of Decomposition of Salts.*" By G. H. BAILEY, D.Sc., Ph.D.

The apparatus is for the purpose of maintaining a substance at a given temperature for a prolonged period, and permits of the temperature attained being determined, while any change taking place in the substance can be observed. The author proposes to apply it in the first instance to the study of sulphates used in atomic weight determinations. The bulb of an air-thermometer and a narrow tube into which a boat containing the salt to be heated can be introduced are fixed side by side in a hard glass jacket tube, in shape like a test-tube, which can be heated in an iron tube furnace; the capillary stem of the air thermometer is bent at a right angle and its end is connected by a ground joint to the one limb of a U-tube, charged with mercury, fixed in front of a graduated scale; the other limb of the tube is arranged to act as a gas regulator. The position of the mercury at various temperatures having been once for all determined, it is easy to observe the temperature within the tube to which the substance is subjected; the temperature can be maintained constant to within a degree or two even at high temperatures; and the substance may be withdrawn for examination whenever necessary, or products of decomposition may be sucked out from the tube.

54. "*The Retention of Lead-Salts by Filter-Paper.*" By L. TRANT O'SHEA.

The absorption effect of filter-paper on dilute solutions of metallic salts has not, so far as the author has been able to ascertain, been studied. His attention was drawn to the subject whilst estimating small quantities of lead in water acidulated with sulphuric acid: although the water was perfectly clear, there was a considerable excess of lead in the unfiltered water over that in the water filtered through a single fluted filter-paper.

To test the generality of the phenomenon, various kinds of filter-paper were used. In all the experiments a solution of lead acetate containing 6 m.grms. lead per litre (0·42 grain per gal.) was used, and in each case 50 c.c. (= 0·3 m.grm. Pb) was passed through the filter-paper folded in the ordinary conical form.

Filter-paper.	M.grm. Pb in 50 c c. sol. after filtering through— One filter-paper, 7 c.m. diam.			Two filter-papers, 7 c.c. diam.	
Schleicher u. Schüll	0·18	0·13	0·15	0·06	0·05
English	0·10	0·09	—	0·03	0·05
French, white	0·11	0·11	—	0·05	0·04
„ grey	0·15	0·17	—	0·06	0·03
German, thin (595)..	0·17	0·15	—	0·02	0·02
„ thick (597)	0·15	0·10	0·13	0·00	—
„ thickest ..	0·15	0·13	0·08	0·04	0·06

Though illustrating the phenomenon, these results are not strictly comparable, since the filter-paper was not kept constantly full; consequently larger filter-papers were used which when folded would hold 50 c.c. and the time of filtration noted.

English Filter-paper.

M.grms. Pb in 50 c.c. filtered sol.	0·14	0·18	0·1	0·07	

Washing the filter-paper with water after filtration does not effect the removal of the absorbed salt. A Schleicher and Schüll filter-paper, No. 589, *absorbed* during one filtration of 50 c.c. of solution a quantity of salt equivalent to 0·12 m.grm. lead; it then was washed twice with 50 c.c. water—

1st washing *contained* .. 0·02 m.grm. Pb.
2nd „ „ .. 0·00 „

On filtering the same solution twice through the same filter-paper, a quantity of salt equivalent to 0·24 m.grm. Pb was absorbed, and on treating with 50 c.c. water nothing was washed out.

Not only does the absorption take place during filtration but also when the paper is immersed in the lead solution, although at a much slower rate; the amounts of lead remaining after immersing a paper 7 c.m. in diameter in 50 c.c. solution (= 0·3 m.grm. Pb) were as follows:—

Research Fund.

A meeting of the Research Fund Committee will be held in June. Fellows desiring grants are requested to make application before June 10th.

At the next meeting, on June 3rd, the following papers will be read:—

"The Effect of Re-melting on the Properties of Iron. Notes on Sir Wm. Fairbairn's 1853 Experiments." By Thomas Turner.

"Some Ammonium Compounds and other Derivatives of (α1') Hydroxyquinoline." By C. A. Kohn, B.Sc., Ph.D.

CORRESPONDENCE.

WATER FOR BOILER PURPOSES.

To the Editor of the Chemical News.

Sir,—I write this letter to see if I can induce some of your English contributors (who have done so much good work in the matter of water analysis) to give any suggestions or results of their investigations upon methods of analysis of, and manner of reporting, *waters for boiler purposes*. The problem is simply this:—To determine reasonably, rapidly, and sufficiently accurately, such constituents of a water, that, by knowing their amounts, we can calculate its scale-forming power. The tests of its hardness, temporary or permanent, or both, by Clark's process or its modifications, or by any other similar method, do not answer the requirements, being not sufficiently accurate; that is one extreme. The other extreme is a complete analysis, such as is made of a mineral water, or as a scientific investigation. Something between the two is wanted; for example, reporting SiO_2, $Al_2O_3+Fe_2O_3$ (to be determined together, save when an abnormal amount of either is present), $CaCO_3$, $MgCO_3$, $CaSO_4$, and alkalies. Such an analysis to be made within three days.

I take up such a standard minor work in this country as Cairns's "Manual of Quantitative Chemical Analysis" is, and read, under "Fresh Water," that "The determination of its value as a potable water can be made by a short and simple analysis, showing the amount of silica, alumina, and oxide of iron, lime, magnesia, soda, potash, chlorine, sulphuric acid, organic and volatile matter (expelled by ignition from the residue left after evaporating a given quantity of water), and ammonia, both free and in a form styled albumenoid, which latter is thought to indicate constituents very detrimental to health. Besides, it is important to know its hardness, or soap-destroying power. This analysis will furnish all the information that is requisite to estimate the fitness of water for use in steam boilers, and for manufacturing purposes." I should say it would; it gives *more* information than is needed or wanted. I object decidedly to such an analysis being called "short and simple," even by omitting the steps pertaining to the character of the organic matter present, which cuts no figure in the discussion I would like to open. For some college professors who have plenty of spare time, or who do not have many waters to examine, such a long analysis may do; but for commercial analysts, or for those who, like myself, are connected with corporations, and who may have, as I have, hundreds—if not thousands—of samples to test, the element of time is an exceedingly important one.

While I am not an old chemist, yet an experience of about fourteen years in chemical work, and much of it spent on waters, has given me a profound distrust of the ordinary water analysis; so much so that I am inclined to believe the average analysis, detailing each constituent to the sixth place of decimals perhaps, to be *entirely incorrect*. We have in this country many an M.D. who can make a water analysis with the utmost ease—and inaccuracy! My chief reason for this disbelief is based upon the fact that all the combinations range from the determinations of the alkalies. Have these incorrectly determined and the ensuing calculations are at fault, resulting in incorrect combinations of the bases and acids. Much care has to be taken in the determination of the alkalies by the usual methods, *i. e.*, by treatment with baric hydrate, ammonic carbonate, hydrochloric acid, ammonic chloride, and subsequent separation of the alkalies by $PtCl_4$. The difficulty lies in *obtaining the alkalies pure*. $MgCl_2$ will sometimes hang on to the very last, and it becomes difficult to prevent its re-dissolving, unless one approaches the opposite danger of insufficient washing. Experiments I have tried upon mixtures of known amounts of pure NaCl, KCl, $CaCO_3$, $CaSO_4$, $MgCO_3$, and $MgCl_2$ showed me that sometimes *twenty* leachings and washings were necessary before all the $MgCl_2$ was extracted and the alkalies left pure. The tediousness and uncertainty of the alkali separation makes the "washing process" given below preferable.

The trouble with any brief method of water analysis is chiefly due to the $CaSO_4$. Thus one can determine SiO_2, $Al_2O_3+Fe_2O_3$, CaO, and MgO as usual. Combining MgO to $MgCO_3$ may do, but it is obvious that the CaO cannot all be figured to $CaCO_3$, for $CaSO_4$ is always present to a greater or lesser degree. If SO_3 is determined, one has not the right to unite it all to the CaO, for some may belong to K and Na. But determining the latter (and Cl) gives us the complete analysis I am trying to avoid.

The process we at present use for the regular analysis, $CaSO_4$ and alkalies, and which partially satisfies us, is as follows:—For each determination we make it an invariable rule to use 1 litre, so that no possible error may be afterward multiplied. We start evaporating at the same time, 1 litre for the total solids and 1 litre for the regular analysis. In the latter we determine SiO_2, $Al_2O_3+Fe_2O_3$ (in ordinary waters it makes a very slight difference whether the latter is reported as given or as $FeCO_3$), CaO, and MgO. The residue from the former, after weighing it as "total solids," is treated with 100 c.c. *boiling water* (in portions), which is supposed to extract *all* the alkalies, *all* the $CaSO_4$, *none* of the $CaCO_3$, and *some* of the $MgCO_3$ (and $MgSO_4$ if present), and filtered. To the filtrate is added NH_4HO and $(NH_4)_2C_2O_4$, whereby both CaO and MgO are precipitated. No HCl is ever added, so that no NH_4Cl can be introduced into the analysis to hold up MgO. The precipitate of the oxalates of CaO and MgO is filtered and washed, and the filtrate evaporated to dry-

ness, and weighed as the "*alkalies by washing*." The precipitate is dissolved in HCl, the solution made alkaline with NH_4HO, again made acid with HCl; finally the CaO is precipitated with NH_4HO and $(NH_4)_2C_2O_4$ as usual, and considered as the $CaSO_4$ of the original water. Wanklyn's method in Chap. II., and p. 95 of Chap. IV. of his 6th ed., consists in weighing his soluble solids, then determining the CaO and MgO in them; the difference he calls alkalies: in our variation we actually weigh them. The CaO existing as $CaSO_4$ is deducted from the total CaO, and the remainder calculated to $CaCO_3$.

Now is the above process a correct one? In waters free from the interference of much organic matter we have found that our "alkalies by washing" come very close to "alkalies by difference," *i.e.*, the difference between the sum of the constituents and the "total solids on evaporation."

So much for the alkalies. As for $CaSO_4$ the question is whether $CaSO_4$ alone, or whether some of the $CaCO_3$ is extracted by the hot water. The statements in the authorities as to the solubilities of CaO and MgO salts vary, so that it is perplexing to know which to accept and which to reject. The following experiments bear on this point:—

A. A mixture of 20 m.grms. pure $CaSO_4$ and 500 m.grms. of a very pure dolomite (composed of 293 m.grms. $CaCO_3$, 201 m.grms. $MgCO_3$, 1 m.grm. SiO_2, and 4½ m.grms. $Al_2O_3+Fe_2O_3$) was evaporated with water to dryness in a platinum dish, and the residue treated with 100 c.c., in portions, of boiling water, and filtered. In the filtrate the lime was determined, while the residue was again treated with 100 c.c. water, filtered, and the lime in its filtrate determined. The residue was a third time treated with 100 c.c. hot water, and the lime determined in the filtrate. Results:—

1.	100 c.c. extracted	10·6	m.grms.	$CaSO_4$.
2.	,, ,,	3·1	,,	,,
3.	,, ,,	3·5	,,	,,
	Total	17·2	,,	,,

(or 2·8 m.grms. short.)

B. Same amounts of same kind of mixture, treated with 400 c.c. boiling water, in portions.
Extracted 20·1 m.grms. $CaSO_4$, or 1-10th m.grm. too much.

C. 40 m.grms. $CaSO_4$ and 500. m.grms. dolomite, with 400 c.c. hot H_2O.
Extracted 31·3 m.grms. $CaSO_4$, or 8·7 m.grms. short.

D. 40 m.grms. $CaSO_4$ (no dolomite), with 500 c.c. hot H_2O.
Extracted 32·5 m.grms. $CaSO_4$, or 7½ m.grms. short.

E. 20 m.grms. $CaSO_4$ (no dolomite), with 500 c.c. hot H_2O.
Extracted 16 m.grms. $CaSO_4$. (The last two trials extracted almost exactly ½ each time.)

I could say more, but feel I have no right to use up more of your space. Still I would like to call attention to the advisability of making reports so that they shall be intelligible to those for whom such work is done. In my case, after giving the chemical data of so many grains per U.S. gal. of SiO_2, $Al_2O_3+Fe_2O_3$, $CaCO_3$, $CaSO_4$, $MgCO_3$ (in some cases $MgSO_4$), alkalies by washing and total solids, we append a second table, which gives the number of grains of "incrusting solids" (all of the above constituents save the alkalies), the number of pounds of these incrusting solids which our standard locomotive tank of 2750 gals. would contain if filled with the water in question, and finally a comparison, giving same data of our standard (Lake Michigan water), and a column in which the Lake Michigan water as unity (1°) is compared with the water in question as (generally) something higher, based upon the varying amounts of incrusting solids.—I am, &c.

WALTER LEE BROWN,
Chemist C. B. & Q. R.R. Co.

Chicago, Burlington, and Quincy Railroad Company, Test Department, U.S.A., Chemical Laboratory, Aurora, Ill., May 11, 1886.

CHEMICAL NOTICES FROM FOREIGN SOURCES.

NOTE.—All degrees of temperature are Centigrade unless otherwise expressed.

Comptes Rendus Hebdomadaires des Séances, de l' Académie des Sciences. Vol. cii., No. 19, May 10, 1886.

Formation of Oxalic Acid in Vegetation.—MM. Berthelot and André.—The authors discuss the formation of oxalic acid in *Amaranthus caudatus*, *Chenopodium quinoa*, and *Mesembrianthemum crystallinum*.

Sounds produced in Vibrating Plates by Discharges of Static Electricity.—E. Semmola.—If a metal plate is traversed by frequent discharges from an electric machine they give a very faint sound, quite distinct from the noise of the spark. To hear these sounds it is necessary to fix the metal plate to the end of a sound collector of ebonite, which is held near to the ear. The sounds become more acute in proportion as the discharges succeed each other more rapidly. The sound is also obtained from a metal plate placed close to a conductor traversed by electric discharges.

Secondary Electrolysis.—E. Semmola.—A small slip of platinum is immersed in the acidulated water of a voltameter, so that its ends may be opposite the electrodes of the voltameter. If an electric current of sufficient intensity is passed into the voltameter there is an escape of hydrogen and oxygen not merely at the electrodes of the voltameter, but also at the extremities of the immersed slip of platinum, which the author calls a third electrode and which acts like a new voltameter. If, instead of platinum, an easily oxidisable metal is employed, this secondary electrolysis becomes much stronger.

The Decomposition-Products of Hypophosphoric Acid: Secondary Hydrate.—A. Joly.—The author refers to a secondary hydrate which he described in *Comptes Rendus*, ci., p. 1058, and cii., p. 110. If the hypophosphoric hydrate is kept a little below 62° the temperature of the melted acid rises gradually several degrees above the temperature of the surrounding medium, indicating that the melted acid is the seat of an exothermic decomposition. The liquid no longer crystallises entirely on cooling, and the portion which remains liquid gives the reaction of phosphorous acid.

Definite Compounds of Hydrochloric Acid and Zinc Chloride.—R. Engel.—The author obtains two distinct compounds of hydrochloric acid and zinc chloride. He finds also that anhydrous zinc chloride may exist in presence of an aqueous solution of zinc chloride.

Combinations of Quinone with the Benzoic Phenols.—MM. de Clermont and Chautard.—The authors have studied the action of the chlorides of acids upon phenoquinone by bringing it in contact with a large excess of acetyl chloride. Monochloro-monacetylic hydroquinone crystallises in silky tufts or in rectangular prisms, perfectly transparent and melting at 62°. Acetyl bromide and benzoyl chloride yield analogous compounds. The author has prepared a third combination of quinone with a diatomic phenol by setting out from pyrocatechine. The new compound forms deep green crystals melting at 153°. Pyrogalloquinone has been previously obtained by Wichelhaus as an instance of the combination of quinone

with a triatomic phenol. Phloroquinone is obtained by bringing in contact 2 mols. phloroglucine and 1 mol. quinone, both in ethereal solutions. It forms fine rectangular tabular crystals, red by transmitted but green by reflected light.

Action of Phosphorus Perchloride upon Hydrocarbons.—A. Colson and H. Gautier.—Phosphorus perchloride renders it possible to prepare symmetric chlorine compounds both in the fatty and the aromatic series, to the exclusion of the isomers which always accompany them if prepared in other manners.

The Rancidity of Butter.—E. Duclaux.—The rancification of butter is not an affair of microbia; it is a spontaneous decomposition of the glycerides of butter. Water promotes it; acidity accelerates it more than alkalinity; salt and borax retard it. All the ethers of butter do not undergo it equally. Butyrine is the least stable, then caproine and the glycerides of the fixed acids. The author suggests the use of water saturated with carbonic acid for washing butter.

Sozolic Acid or Orthoxyphenylsulphurous Acid.—M. Serrant.—The author has previously described this compound under the name of aseptol. Sozolic acid is a true acid surpassing salicylic and phenic acids as an antiseptic.

Berichte der Deutschen Chemischen Gesellschaft zu Berlin
Vol. xix., No. 3.

A Reply.—J. Herzig.—Remarks on Prof. Liebermann's critique on the author's memoirs on quercetine and rhamnetine.

Germanium, Ge, a New Non-Metallic Element. C. Winckler.—The substance of this paper has been already inserted.

Influence of Light on the Progress of Chemical Reactions during the Action of the Halogens upon Aromatic Compounds. — (Fourth Memoir). — Julian Schramm.—Mesitylen is not sensitive to light under the influence of bromine. Mesityl bromide, which is readily formed with the aid of heat, is not formed with the aid of the sun's rays. Monobrom-mesitylen is sensitive to light and on treatment with 1 mol. bromine under these conditions yields para-brom-mesityl-bromide. If pseudocumol is bromised in the sun the hydrogen atoms in the lateral chains are substituted.

Condensation of Bodies of the Urea-Group with Acetacetic Ether.—R. Behrend.—Phenyl-urea combines with acetacetic ether, water being eliminated. The behaviour of sulphurea and of guanidine with acetacetic ether has been studied respectively by R. List and A. Kœhler.

On the Cyanhydrine of Levulose.—(Second Communication).—H. Kiliani.—The author describes the preparation of levulose-cyanhydrine and its behaviour with metallic hydroxides.

On Ethyl-*n*-Propylacetic Acid.—H. Kiliani.—An account of the calcium, strontium, barium, silver, lead, and copper salts of this acid.

On Mixed Methyl-ketones and their Oxidation to α-Ketonic Acids.—A. Claus.—The conclusions to be drawn from the author's results are that the acetyl residue, and in an analogous manner acid residues in general, on their entrance into conjugated hydrocarbons take, if possible, the para-position to a lateral chain, and secondly, the ortho-position to the shortest lateral chain of benzol. Only those methyl-ketones can be directly oxidised to α-ketonic acids in which one lateral chain is in the ortho-position to the ketone-combination.

Reply to A. Jacobsen's Notice on the "History of the Orthoxylidines."—E. Wroblewsky.—A reply to a paper contained in *Berichte* (xviii., No. 17), in which the writer seeks to refute the view that the adjoining xylidine can be prepared by means of the acetyl-derivatives from the mixture of the xylidines as obtained by the reduction of nitrised xylol.

On β-Nitro-naphthaline.—E. Sellman and A. Remy.—The substance which one of the authors formerly described as γ-nitro-naphthylamine, melting at 144°, is found, according to more recent researches, to have the constitution of an orthonitro-α-naphthylamine. It furnishes a suitable material for the preparation of β-nitro-naphthaline.

The Products of the Dry Distillation of some Fatty Salts of Silver.—F. Iwig and O. Hecht.—The authors have examined silver acetate and butyrate. The only demonstrable products obtained from the former are silver, carbon, acetic and carbonic acids, no ethylene or any other combustible gas having been detected. Silver butyric yields essentially the same products, normal butyric acid appearing in place of the acetic.

A Contribution to the Knowledge of the Cyanuric Derivatives.—H. F. Fries.—The author has obtained and examined mono-α-naphthylamised cyanurchloride, the corresponding dicompound, and trinaphthylmelamine.

Propyl Group of Thymol. — O. Widman. — The author demonstrates that normal propyl is present in thymol.

Ortho-Derivatives of Cumenylacrylic Acid, and Chinoline Derivatives thence obtained.—O. Widman.—This very extensive paper does not admit of useful abstraction.

Oxidation Products of Orthonitic Cumenylacrylic Acid, and Compounds therefrom obtained. — O. Widman.—This paper contains accounts of ortho-nitro-cuminic acid, ortho-amido-cuminic acid, ortho-nitro-para-oxypropyl-benzoic acid, ortho-amido-oxypropyl-benzoic acid, ortho-acetamido-oxypropyl-benzoic acid, and ortho-amido-propenyl-benzoic acid.

New Transpositions within the Propyl Group.—O. Widman.—It appears that on simple nitration with fuming nitric acid at 0°, the isopropyl group of cumenyl-acrylic acid is partially transposed into normal propyl. This shows that the acrylic residue, like the methyl group, affects a propyl group in the para position, and predisposes to the formation of normal propyl.

On Nitrosophenol-hypochlorous Ester.—R. Möhlan.—The author undertakes to demonstrate that all the isonitroso- or oximido-compounds, hydroxylamine not excepted, are capable of forming hypochloric esters.

On Symmetric Pyridine-tetracarbonic Acid and ββ′ Pyridine-dicarbonic Acid. — A. Hantzsch and L. Weiss. — The authors have obtained the two acids in question and examined several of their salts.

Isomerism of the Pyridine-dicarbonic Acids.—A. Hantzsch.—A discussion of the identity of these acids. The author considers that Ramsay's α-pyridine-dicarbonic acid represents a chemical individual, and agrees in its essential attributes with αα′ dicarbonic acid.

On Krokonic and Leukonic Acid.—R. Nietzki and T. Benckisser.—This voluminous memoir does not admit of useful abstraction.

On Cyanur-chloride and Cyanuric Acid.—A. Senier. The author examines the behaviour of cyanur-chloride with the salts of various organic acids, and the action of benzoyl chloride upon silver cyanurate.

Journal für Praktische Chemie.
New Series, Vol. xxxiii., Part 6.

On the Melam Compounds.—Peter Klason.—Liebig's "pure melam" is a mixture of melam and melem. The former body in contact with acids or alkalies is resolved into ammelin and ammonia, whilst the latter under the same circumstances yields ammelide and ammonia.

Influence of Neutral Salts and of Temperature on the Inversion of Cane-Sugar by Acids.—(Second Treatise).—J. Spohr.—Every acid at each degree of concentration has a certain constant of inversion which is in regular connection with the magnitude of its affinity. The magnitudes of the affinity of one and the same acid at different concentrations are in a determinate regular connection among themselves and with those of other acids. The magnitudes of the affinity of the acids in question are increased under all circumstances by the addition of a neutral salt. The magnitude of the strengthening of affinity by neutral salt added increases with the magnitude of the affinity. The constants of inversion of all acids increase with an increasing temperature almost in the same proportion.

On Normal Melamines.—Peter Klason.—The author describes melamine, trimethyl- and triethyl-melamine, triphenyl- and para-tritolyl-melamine, mono-phenyl-melamine ammeline, thio-ammelin, normal ammelide (Liebig's melanuric acid), ethyl amido-dithio-cyanurate, and diamidothio-cyanurate, and amyl amidothio-cyanurate.

The Oxidation of Oleic and Elaidinic Acids with Potassium Permanganate in an Alkaline Solution.—A. Saytzeff.—This extensive paper does not admit of useful abstraction.

A Process for the Synthesis of Homologues of Anthraquinone.—K. Elbs.—The condensation of ortho-benzoyl-benzoic acid to anthraquinone or anthraquinon-sulphonic acid has long been known, but the attempt has never been made to transform its homologues into the corresponding anthraquinones. This, however, can be effected with tolerable ease and completeness.

Justus Liebig's Annalen der Chemie,
Vol. ccxxxii., Part 2.

Researches on the More Complicated Amidic Acids derived from Meta-amido-benzoic Acid.—These researches consist of a paper by Hugo Schiff, on oxalamido-benzoic acids; a memoir on the benzamic acids of certain monobasic and bibasic acids, by G. Pellizzari; and a paper, by Hugo Schiff, on tartramido- and melamido-benzoic acids.

Examination of Melitose or Raffinose from Treacle, Cotton-seed, and Eucalyptus Manna.—This first dissertation consists of an introduction by B. Tollens; an account of experiments on the raffinose of treacle and cotton-seed, by Dr. P. Rischbiet and B. Tollens; a paper on the melitose from Eucalyptus manna, by B. Tollens; and an attempt, by R. Creydt and B. Tollens, at a quantitative determination of the raffinose in mixtures.

Communications from the Chemical Laboratory of the University of Erlangen.—These consist of papers by Hugo Weil, on diacetonamine; by S. Hegel, on certain derivatives of indol; by E. Fischer and H. Koch, on certain derivatives of trimethylen- and ethylen-diamine; by Max Pickel, on some compounds of phenyl-hydrazine; and by Otto Hess, on the action of brom-acetophenon upon phenyl-hydrazine.

On Naphthyl-hydrazines.—Emil Fischer.—The author describes the preparation of α-naphthyl-hydrazine, and gives an account of its hydrochlorate, sulphate, nitrate, oxalate, and acetate. He has also examined α-naphthylhydrazin-pyruvic acid, aceton-α-naphtyl-hydrazine, its behaviour with nitrous acid, and β-napthyl-hydrazine and some of its salts.

Sulphur Compounds of Tungsten.—Ehrenfried Corleis.—The author has examined the ozysulpho-tungstates, *i. e.*, potassium monosulpho-tungstate, ammonium disulpho-tungstate, potassium trisulpho-tunstate; also the sulpho-tungstates, including normal ammonium sulpho-tungstate and the corresponding potassium and sodium compounds. The following reactions serve to distinguish the normal sulpho-tungstates from the oxy-sulpho-tungstates. If the solution of a sulpho-tungstate is covered with a mixture of alcohol and ether, and hydrochloric acid is added, the ethereal solution becomes dark brown, whilst the watery stratum appears clear and colourless. Oxysulpho-tungstates, if similarly treated, give likewise an ethereal solution more or less deeply coloured, whilst the aqueous stratum is turbid and milky. The two salts may be distinguished by means of solution of zinc sulphate. This does not render the normal sulpho-tungstates turbid. In the solution of a trisulpho-tungstate there soon appears a lemon-yellow turbidity, which becomes a copious yellow precipitate, soluble in hydrochloric acid, with a reddish brown colour. In this solution there soon appears a dark grey-blue precipitate. The solution of a disulpho-tungstate gives an immediate light yellow precipitate with zinc sulphate. Hydrochloric acid renders the liquid clear again, but a dirty blue precipitate is soon formed. Monosulpho-tungstates give the zinc sulphate a white precipitate, soluble in hydrochloric acid. This solution, on standing, deposits a white precipitate, which soon takes a bluish shade. The formation of the sulpho-tungstic acids seems in part dependent upon the base, as on the action of hydrogen sulphide upon potassium tungstate there are formed mono- and trisulpho-tungstates, whilst if the ammonium salt is taken the disulpho-tungstate and the normal sulpho-tungstate are formed. Tungsten therefore in this respect behaves similarly to molybdenum.

On Hypophosphoric Acid.—T. Salzer.—The author contests Sanger's view that this acid, on concentration, is resolved not into phosphorous and pyrophosphoric acids, but into phosphorous and orthophosphoric acids.

MEETINGS FOR THE WEEK.

Tuesday, June 1st.—Royal Institution, 3. "The Function of Circulation," by Prof. Arthur Gamgee, F.R.S.
Thursday, 3rd.—Royal Institution, 3. "Habit as a Factor in Human Morphology," by Prof. A. Macalister, F.R.S.
—— Chemical, 8.
Friday, 4th.—Royal Institution, 9. "The Sympathetic Nervous System," by W. H. Gaskell, F.R.S.
—— Geologists' Association, 8.
Saturday, 5th.—Royal Institution, 3. "Light, with special reference to Effects resulting from its Action on various substances," by Prof. Stokes, Pres.R.S.
—— Physical, 3. "On Electric Light Fire-Damp Indicators," by Messrs. W. Emmott and W. Ackroyd.

NOTES AND QUERIES.

THE CHEMICAL NEWS.

Vol. LIII. No. 1384.

HOLMIA, THE EARTH X OF M. SORET, CONTAINS AT LEAST TWO METALLIC RADICLES.

By M. LECOQ DE BOISBAUDRAN.

The author demanded the opening of a sealed paper which he had deposited on April 27, 1886. This paper, marked No. 4044, was opened during the session by the Perpetual Secretary and contained the following memoir :—

In October, 1878 (*Comptes Rendus*, lxxxvii., p. 559), M. Delafontaine announced a new earth, philippia, and ascribed to it the strong absorption-band situate at about 164·25 of the author's scale (λ=451·5), which band was included in the spectrum of the former erbia.

In the beginning of 1880 (*Comptes Rendus*, xc., p. 221) M. Delafontaine recognised that the band 451·5 is due to the same body as the other bands considered by M. Soret and M. Clève as characteristic of holmium. M. Delafontaine added that this holmium was identical with his philippium, and in particular that no fact hindered him from admitting that the band 451·5 was derived from the same body as the bands 640·4 and 536·3.

Lastly in August, 1880 (*Comptes Rendus*, xci., p. 378), and September, 1880 (*Archives des Sciences Physiques et Naturelles*, p. 80; Geneva, Sept. 15, 1880), M. Soret recalled the fact that M. Delafontaine had renounced his old idea of the identity of holmium and philippium on finding that the latter body gave no visible absorption-spectrum, and that the bands which he had ascribed to it at first really belong to holmium.

It results from this short historical summary of the question :—

1. That M. Delafontaine's philippium has no absorption-spectrum.
2. That all the bands of the following table, drawn up by M. Soret, are at present regarded as belonging to a single element, holmium.

Visible Spectrum of the Earth X or Holmia.

804 (?)	Very strong.
753	Weak.
640·4 } 536·3 }	Very characteristic.
485·5	
474·5	Very weak and misty.
453 to 449	
430	Doubtful.
414·5	
389 to 387.	

The author has, however, succeeded by means of several hundred fractionations with ammonia and potassium sulphate, in obtaining earths showing very plainly 753 and 451·5, in the complete absence of 640·4 and 536·3, and on the other hand earths showing 753 and 451·5 much more faintly, though 640·4 and 536·3 were seen very distinctly. The oxide hitherto called holmia is therefore not homogeneous, and contains *at least* two radicles.

As the bands 640·4 and 536·3 are those especially which served M. Soret and M. Clève for recognising the presence of a new element in the old erbium, the author proposes to retain the name holmium for the element which produces these bands, and to call the metal giving the bands 753 and 451·5 *dysprosium** (Dy).

* From δυσπρόσιτος, difficult to approach.

The question has now to be decided whether 640·4 and 536·3 are really due to the same earth, and a similar question arises for 753 and 451·5.

M. Soret indicates 753 as faint. The author sees it very strong in specimens which give neither 640·4 nor 536·3, whilst it is almost null in cases where 640·4 and 536·3 are quite distinct, and where 451·5 is still seen plainly, though much attenuated. According to the present state of the author's observations the bands 753 and 451·5 seem to follow the same variations in intensity.

As for the other bands contained in the above table they have to be classified to see if they can all be distributed between the spectra HO and Dy. In fractionations with potassium sulphate and alcohol the first precipitates contain especially the terbia, then come dysprosia, holmia, and lastly erbia.—*Comptes Rendus*, cii., p. 1003.

ON DYSPROSIUM.

By M. LECOQ DE BOISBAUDRAN.

Since the deposit of the sealed paper above referred to the author has continued his observations, which he here summarises.

The earths which no longer show the absorption-rays of holmium (640·4 and 536·3), but which give very distinctly the bands of dysprosium (753 and 451·5), are still very rich in terbia. Still these bands (753 and 451·5) cannot be ascribed to terbia itself any more than the others spoken of, since they are notably stronger in earths which are relatively pale than in the most highly-coloured terbia. But a deep reddish yellow tint is the distinguishing character of terbia.

The bands of Dy are not due to erbium, samarium, or didymium, the chief rays of which are invisible in the author's best preparations. The fractionations with potassium sulphate and alcohol always eliminated didymium and samarium at the beginning of the series, and erbium at the end, even beyond holmium.

With earths thus purified there are seen, besides 753 and 451·5,—

1. A certain indication of 804. This band is at the extreme limit of the spectrum visible in the author's instrument. Its presence only has been distinguished, and that not without difficulty.
2. A large nebulous band, having its centre placed at about 148·3 of the author's scale (λ=475). This band must not be confounded with that, narrower and a little more refrangible, which is easily seen when holmium is abundant, and for which its author gives the following position: Ho, 149·1, λ=473·7, apparent middle. Width about 2½ divisions. More nebulous on the left than on the right.
3. A ray or narrow band, probably that indicated by M. Soret as doubtful at λ=430. The author gives its position as 183·7, λ+427·5. This band is easily visible in all his preparations of pure dysprosium,* and in mixtures containing both dysprosium and holmium.

To sum up, the following bands undergo the same variations of intensity, and seem due to dysprosium. The author makes reservations, however, as regards 804, which he has not yet studied sufficiently. With this exception he gives the following determinations which he has made, considering them, however, as merely provisional and approximate :—(See Table next column).

The author has long been satisfied of the impossibility of ascribing the band β 148·3 (λ=475) to any known body, including holmium, as defined by its absorption-spectrum given in M. Soret's table. But the uncommon difficulty of separating dysprosium from holmium and erbium, on

* Pure as regards the absorption spectrum, but containing much terbia.

Micrometer.	λ	
	804·0	Broader than 756·3, but much less apparent. (Perhaps from the want of light in this portion of the spectrum ?)
γ. 67·06 about.	756·5	Rather narrow. M. Soret gives its position λ=753, but it ought to be the same band.
β. 148·3 about.	475·0	Very nebulous, and from 4¼ to 5 divisions of the micrometer in breadth.
α. 164·2	451·5	Nebulous outlines, but less vague than those of the former. Breadth from 4 to 4½ degrees of the micrometer. Much stronger than 475.
δ. 183·7 about.	427·5	Rather narrow, but seeming a little broader than 756·5.

the one hand, and from terbium on the other, has induced him to keep back this observation.

The lack of material arising from the numerous fractionations has been a great hindrance in this investigation. —*Comptes Rendus*, cii., p. 1005.

RELATION OF "TRANSFER-RESISTANCE" TO THE MOLECULAR WEIGHT AND CHEMICAL COMPOSITION OF ELECTROLYTES.*

By G. GORE, LL.D., F.R.S.

In the full paper the author first describes the method he employed for measuring the "resistance," and then gives the numerical results of the measurements in the form of a series of tables.

He took a number of groups of chemically related acids and salts of considerable degrees of purity, all of them in the proportion of their chemical equivalent weights, and dissolved in equal and sufficient quantities of distilled water to form quite dilute solutions. The number of solutions was about seventy, and included those of hydriodic, hydrobromic, hydrochloric, hydrofluoric, nitric, and sulphuric acids; the iodides, bromides, chlorides, fluorides, hydrates, carbonates, nitrates, and sulphates of ammonium, cæsium, rubidium, potassium, sodium, and lithium; the chlorides, hydrates, and nitrates of barium, strontium, and calcium; and a series of stronger solutions, of equivalent strengths to each other, of the chlorides of hydrogen, ammonium, rubidium, potassium, sodium, lithium, barium, strontium, and calcium. A series of similar liquids to those of one of the groups of acids, of equal (not of equivalent) strength to each other, was also included.

As electrodes he employed pairs of plates of zinc, cadmium, lead, tin, iron, nickel, copper, silver, gold, palladium, and platinum; and separate ones formed of bars of iridium.

He took each group of solutions, and measured in each liquid separately, at atmospheric temperature, the "total resistance" at the two electrodes, and the separate "resistances" at the anode and cathode respectively with each metal, and thus obtained about seventy different tables, each containing about thirty-six measurements, including the amounts of "total," "anode," and "cathode resistance" of each metal, and the "averages" of these for all the metals.

By comparing the numbers thus obtained, and by general logical analysis of the whole of the results, he has arrived at various conclusions, of which the following are the most important:—The phenomenon of "transfer-resistance" appears to be *a new physical relation of the atomic weights*, attended by inseparable electrolytic and other concomitants (one of which is liberation of heat,—*Phil. Mag.*, 1886, vol. xxi., p. 130). In the chemical groups of substances examined *it varied inversely as the atomic weights of the constituents, both electro-positive and electro-negative, of the electrolyte, independent of all other circumstances*; and in consequence of being largely diminished by corrosion of the electrodes, it appeared to be intimately related to "surface-tension." He suggests that such corrosion may be a consequence, and not the cause of small "transfer-resistance." The strongest evidence of the existence of the above general law was obtained with liquids and electrolytes with which there was the least corrosion and the least formation of undissolved films: those liquids were dilute alkaline chlorides, with electrodes of platinum.

This research is an extension of a former one on "Transfer-resistance in Electrolytic and Voltaic Cells," communicated to the Royal Society, March 2nd, 1885. Further evidence on the same subject has been published by the author, in the *Philosophical Magazine*, 1886, vol. xxi., pp. 130, 145, 249.

* Abstract of a Paper read before the Royal Society, May 20th, 1886.

ON AN ERROR IN THE NITROMETRIC ASSAY OF VITRIOL.

By THOMAS BAYLEY.

A short time ago I made a communication on this subject to the Chemical News, which was in effect a reply to Prof. Lunge, who had called in question some experiments I had made on the estimation of nitrogen compounds in vitriol. Prof. Lunge has since returned to the subject. The controversy can be epitomised in a few words. When, after shaking the nitrometer in the usual way for the estimation of "nitre," the evolved gas is measured and allowed to escape, and a quantity of water about equal in volume to the sulphuric acid solution of mercurous sulphate is added, without contact of the latter with air, further shaking frequently causes the liberation of an additional small but varying volume of nitric oxide gas. This *fact*, observed by me, was quoted by Mr. A. H. Allen in a paper on the nitrometer, in support of an opinion, which has been shared by other writers, that nitric oxide is soluble in sulphuric acid. Of course the observation does not afford proof of that hypothesis, although it appears to support it. Prof. Lunge, however, after shaking pure nitric oxide with pure sulphuric acid, and thereby demonstrating the insolubility of the gas in the acid, and nothing more, applied this result to prove that no nitric oxide could be dissolved by the mercurous solution in the nitrometer, although Miller, Watts, Gmelin, and other chemists have ascribed a solvent power over this gas to mercurous and other salts. I admit that I was myself in error when, misled by interpretation of statements by various authors, apparently confirmed by the appearance of the gas in question on dilution of the vitriol, I held the retention of the nitric oxide to be due to the mercurous sulphate. Indeed, further experiments by Lunge and Pattinson show that the mercurous salt has not this power of solution under the conditions of the experiment, and Prof. Lunge now "affirms that these quantities" (of nitric oxide) "dissolved must be, in any case, so minute as to be inappreciable in practical work, and denies that the addition of water causes the operation to be more correct by the liberation of a sensible quantity of nitric oxide previously dissolved in the acid liquid."

My observations must now more than ever be inaccurate; but Prof. Lunge will not now "hazard a guess by what fault of manipulation the inaccuracy arose," but he draws attention to one point which has frequently caused him to reject his own tests: this is the clinging of a drop of acid to the narrow part of the tube under the tap. After the "ordinary" shaking this of course gets washed

down by added water, and would cause a liberation of gas, "0·5, as Mr. Bayley has frequently found, or more or less, according to the original fault in manipulation." I have used the original (Davis's) two-way nitrometer and the three-way instrument (introduced by Lunge), and, with both, the mercury has immediately on shaking formed a froth in this narrow space, and so displaced this film or drop. But after shaking and expelling the gas, both mercury and sulphuric acid have been added through the tap, thoroughly cleansed, in order to wash down this film, and no additional volume of gas has ever appeared, although water has afterwards caused its liberation. These precautions were taken from the beginning, and others in addition, such as the thorough boiling of the water immediately before use in the experiment. This point some further prophet of the nitrometer would do well to call attention to.

Nitric oxide is, however, certainly retained by the liquid in the instrument, not only when using common vitriol (for which the method is most employed), but in the case of much of the "pur" acid of the shops. The latter is purified by dilution, decantation from sulphate of lead, and rectification with ammonium sulphate. It is evident that this will not remove such impurities as copper, iron, and other metals. Iron especially is frequently present; the Pocket-book of the German Alkali-makers contains a method for its estimation involving the use of $\frac{1}{10}$ N permanganate.

The presence of iron is the cause of the solubility of gas in the nitrometer; the following experiments have made this clear.

Iron Solution.

A solution was made by dissolving 0·5 grm. of $FeSO_4$,5aq. in a small quantity of water, and diluting to 50 c.c. with concentrated pure sulphuric acid. This amount of salt is not permanently soluble, but the experiments were made before any crystallised out.

Nitre Solution.

A solution was made containing 0·5 grm. KNO_3 in 50 c.c. of pure conc. sulphuric acid.

One c.c. of nitre solution was shaken in the instrument and 2·2 c.c. of gas were liberated (at 19° C.), pure sulphuric acid being used to wash in the sample.

In another experiment 1 c.c. of nitre solution, washed in with 5 c.c. of the iron solution, in two batches, gave only 0·2 c.c. of gas, even on long standing, 2 c.c. being dissolved; and of this dissolved portion only 0·7 c.c. was liberated by 5 c.c. of water, the solution changing from dark port-wine red to a brownish orange.

Using a sample of Glover acid containing 0·05 per cent of Fe the same dark colour was observed, and 0·4 c.c. was liberated on dilution.

A quantity (1·5 c.c.) of nitre solution having been used, which liberated 3·3 c.c. of gas, 5 c.c. of iron solution, holding some salt in suspension, were added; on shaking for ten minutes nearly all the gas dissolved, and ultimately all but 0·2 c.c. passed into solution.

These experiments may be repeated indefinitely with similar results, and indicate that the presence of iron in common vitriol, and in "*pur.*" sulphuric acid, may cause a not inconsiderable error in vitriol testing. Thus, supposing 5 c.c. of such an acid, as the nitre solution represents, were under trial, each c.c. would dissolve 0·4 c.c. of gas, corresponding to 0·144 grm. of $NaNO_3$ per 100 c.c.; which error would be increased by the use of a similarly vitiated "*pur.*" acid in rinsing in. And if such 5 c.c. of acid, free from nitre, were used in any other nitrometric test, the total volume suppressed (viz., 2·0 c.c.) would not be trivial.

Again, the quantity actually dissolved is an unknown amount, because all is not liberated on dilution with a practicable volume of water.

The colour of the solution affords an estimation of the amount of iron present; 0·002 grm. of the metal imparts a deep port-wine red to 6 c.c. of acid: probably 1-100th of the amount of colour would be appreciated without difficulty. The method might be applied as a colour-test for iron, and for the study of the compounds of iron sulphate and nitric oxide. Salts of copper, cobalt, nickel, chromium, and uranium absorb no gas under the conditions of the experiment. Copper produces a trancient puce colour, and seems to cause absorption at first, but on continued shaking the whole of the nitric oxide is liberated.

THE UNITED STATES LABORATORY AT THE NEW YORK PUBLIC STORES.

By MARCUS BENJAMIN, Ph.B., F.C.S.

SEVEN years ago, at the September term of the District Court of the United States for the district of Maryland, there was tried the famous Demerara Sugar Case. At that time the duties payable on sugar were levied according to the colour, the Dutch Standard being the criterion by which the shade was determined. This standard was simply a series of bottles containing sugars of a known degree of purity, with which the imported sample was compared, and then accordingly classified. For a year or more previous to the trial just mentioned, sugars that were supposed to be artificially coloured or darkened had been imported into this country: but as it was almost impossible to satisfactorily prove such an assumption, no direct efforts to interfere with their introduction were undertaken. The use of the polariscope was agitated, and the matter carefully considered by the Treasury Department at Washington. Meetings of prominent merchants and importers were held in New York and other cities, and the subject was thoroughly canvassed. Finally, a large quantity of artificially darkened sugar was seized, and the trial at Baltimore followed. The jury decided, *first*, "that the sugars were artificially coloured after crystallisation," and, *second*, that "the importer introduced them with an intent to defraud the United States." One striking fact was emphasized throughout all the testimony introduced, irrespective of the side by whom the opinion was advanced. It was that "there is no determinate relation between the colour of sugars and their polarisation or saccharine value." This consideration soon led to the issuing of an order by the Secretary of the Treasury, John Sherman, requiring the adoption of the polariscope for the examination of sugars in the Customs Service, with the gradual abandonment of the Dutch Standard as an authority. The sugar-importing ports were before long equipped with polariscopes, and such articles as were necessary for the analysis of sugar and molasses. Portland, Boston, New York, Philadelphia, Baltimore, New Orleans, and San Francisco received outfits of chemical apparatus, and experts were detailed to prosecute the examinations. The port of New York, which exceeds all the others combined in the value and variety of its imports, was selected as the best locality at which to establish a general chemical laboratory for the Customs service, and it was deemed best that the chemical laboratory should be under the same general management as the sugar laboratory. In the latter part of the year 1878, Dr. William C. Tilden, who had recently acted as Professor of Chemistry at the Howard University, of Washington, D.C., was appointed in charge, and Mr. Edward Mayers, an expert who had given valuable testimony on the side of the Government at the Baltimore trial, was selected to direct the sugar-work. Rooms at 128, Hudson Street, were hired, and the work was begun. Various determinations of morphine, of iron ores, alcohols, &c., were carried on. After a year's experience at the place mentioned, the amount of work having considerably increased, larger accommodations were necessary, and the U.S. Laboratory was moved to the corner of Grand and Varick Streets. In the meanwhile the force had been augmented by the appointment

of Dr. Jesse Park Battershall, a well-known analytical chemist of New York city, and a graduate, with high honours, of the famous German University of Tubingen. This gentleman's experience and thorough chemical knowledge made his services the most valuable acquisition that the U.S. Laboratory has ever received. It is his just due to say that the professional recognition of the work performed under his supervision is about the only consideration that has kept the chemical reports free from suspicion. Dr. Battershall entered the service in July, 1879. Dr. H. M. Baker, a gentleman whose familiarity with dyes and various colouring materials made his services desirable for the examination of the coal-tar products then arriving at this port, had also been appointed for work in this new bureau. Dr. Tilden was subsequently removed, and, in May, 1880, Mr. Edward Sherer, a sugar chemist, was appointed to the control of the laboratory. Two years passed away, and again a removal took place. New quarters were found at 393, Canal Street, over the People's Bank. During the year 1881, 3533 samples of sugars and of syrups or cane-juice were tested by the polariscope, but in March of the following year a decision of the Supreme Court resulted in an order from the Treasury Department discontinuing the use of the polariscope and other chemical tests, and directing that such examinations be made simply by the Dutch Standard of colour. The number of sugar determinations in 1882 were therefore comparatively few, being only some 771 in number, while for the year 1884 the number of polarisations increased to upwards of 30,000.

The amount of work executed in the other divisions of the laboratory during 1882 was of great importance. It was estimated that 115,052·64 dollars of additional duties were collected by the Government in consideration of the information derived from the chemical analyses furnished by Dr. Battershall, on three items alone, viz., oxides of iron, bone-black, and iron ores. Valuable service was rendered by chemically determining the identity of the various dyes that were imported. Such determinations made possible the proper appraisement of the invoices, and thereby enabled the authorities to collect the just amount of duty. On June 1st, 1883, the revised tariff law came into force. An increased amount of chemical work was one of the immediate results of its enactment. New employés, additional facilities, and greater space were at once necessary. The first of these requirements was provided for by adding to the force six examiners, some of whom were only accepted after a Civil Service examination. Among the latter were J. Howard Wainwright, F.C.S., and the writer, both graduates of Columbia College School of Mines.

By the securing and fitting up specially for the U.S. Laboratory the building located at the north-east corner of Hubert and West Streets, the remaining difficulties were apparently overcome. The four floors of this building are in direct communication, forming, in fact, a part of the U.S. Appraiser's stores. Possession of the new offices was taken during the latter part of the summer of 1883, and it seemed as if at last the laboratory had secured a permanent home; but already the space seems too small, and complaint is made that the work is hampered by the lack of room.

Before describing the work performed in each of the three branches of the office, a few observations on the general functions of the laboratory will aid in explaining its field of operations.

It is the only general chemical laboratory connected with the U.S. Customs Service, and therefore various articles are sent to New York for chemical analysis from every other port of entry in the country. Important questions of a scientific nature are frequently received from Washington, demanding a careful investigation at the hands of the experts here in office. Among other duties are the preparation of reports for special agents. This work has frequently been of the greatest value in exposing frauds in importations. The amount of drawback is, whenever possible, determined by chemical analysis.

Besides the foregoing, reports of analyses are furnished to the following divisions of the Appraiser's stores, on the subjects as herewith given:—

4th Division.—Silks and fabrics.
6th ,, —Wool and hair.
7th ,, —Dyes, drugs, and chemicals.
8th ,, —Sugar.
9th ,, —Metals, ores, &c.
11th ,, —Groceries, teas, liquors, &c.

And, also, reports are furnished to the 7th Division of the U.S. Custom-House.

The upper floor of the building is the special domain of Dr. H. M. Baker. In this room the aniline dyes and colours are identified, the different fabrics examined and classified; microscopic examinations of wools and hair are made, besides microscopic examination for the second division, and special investigations required by the Appraiser.

The identification of various hairs forms an exceedingly interesting part of Dr. Baker's work. The specimens are received from the sixth division, and from a microscopical examination it is determined whether the material is goat's hair or camel's. At times samples of human hair have been tested. In the Annual Report for the year 1884, twelve quantitative goat-hair determinations are recorded; four yak-hair estimations are likewise mentioned. The colour estimations are comparative examinations between dyed samples of wool prepared from standards in the possession of the laboratory, and similar samples prepared from the specimen of dye under consideration. A visitor to Dr. Baker's laboratory will often see drying skeins of wool suspended from the ceiling, resplendent with all the brilliant colours of the magnificent coal-tar products, rivalling, in beauty and delicacy of shade, an Eastern flower-garden. The wonders of chemistry are before us, and, as we glance from the lump of crude tar, or from the indifferent aniline oil to the exquisite loveliness of the eosine and many other dyes, we cannot but wonder if the chemist is not in some way connected with the magician of olden times.

The floor beneath is devoted to the analysis of sugar. The work here performed is beyond doubt the most important, from a pecuniary standpoint, of all that is executed in the laboratory. The Report for the month of March, 1885, reads as follows:—

	Tons.
No. of samples tested in duplicate	1567
Samples requiring a third test	65
Total number of tests..	3199
Damaged samples tested 58	
Re-tests performed 84	
Comparative tests 22	
—	164
Making a grand total of	3363

The Annual Report for 1884 stated that 132,022 polarisations of sugars and molasses were made. The estimated cost of this work, if performed by expert chemists outside of the Government employ, was 16,011 dollars, while the actual expense to the United States for this work, including salaries, gas, rent, and apparatus, was only 12,142·13 dols. A saving of 3 868·87 dols. was thereby effected. A better appreciation of this work may perhaps be had from the statement that during the past year there was imported into New York 755,353 tons (2240 lbs. each), having an approximate value of 86,000,000 dols., on which duty to the amount of not less than 25,000,000 dols. was paid.

About ten men are continuously engaged in the work of examining sugar. The crude article is received from the sampling room in tin boxes holding about 1 lb. each. The

sample, or the contents of each box, is thoroughly mixed by being ground in a porcelain mortar, and then handed to the weighers, of whom there are four. After weighing, and 13·024 grms. is standard weight taken, the samples are brought into solution with water in a 50 c.c. flask. When the sugar is completely dissolved a few drops of lead acetate are added. Then the solution is increased exactly to 50 c.c. by adding water, well shaken and filtered, and the filtrate poured into the polariscope tube. There are five polariscopes in constant use in the sugar room. They are of the Scheibler variety, and are made in Berlin, Germany. The law requires the examination of sugar to be made in duplicate, and therefore an agreement to within three-tenths of a per cent is necessary before a report of the saccharine strength of a sample can be made. This sometimes necessitates a re-examination of the sample, and frequently, when the sugar is a poor one, four or five re-tests are made before concordant results are obtained. Examinations of damaged samples of sugar form part of the work required of the experts in this room. Damaged sugars are those which have become injured during the sea voyage to this country, and therefore, in addition to the polarisation, a determination of the amount of moisture contained in the sugar is necessary. This estimation is made by weighing a quantity of the sugar in a porcelain dish, drying at 100° C. to constant weight, and again weighing. The difference between the two weights is the amount of moisture. Every month a series of so-called comparative tests are exchanged between the sugar-importing ports. These tests are simply determinations of moisture and of the saccharine strength by the polariscope, which are verified or "compared" by the receiving port. By this means any important variations in value of the instruments would at once be detected. Mr. Wm. D. Crumbie, one of the examiners connected with the laboratory at New York, tests all the sugar received at New Haven. He is telegraphed for at once on the arrival of a cargo of sugar. The examination of sugars is dispensed with for the present at Portland, Me. During 1884 only 13,380 tons of sugar were received at Portland, New Haven, and other Eastern ports.

Descending another flight of stairs we reach the office and library. The latter is a comparatively well-selected lot of working books. It contains sets of Watts's "Dictionary of Chemistry," Leopold Gmelin's "Handbook of Chemistry" as published by the Cavendish Society, Spon's "Encyclopædia of the Industrial Arts," Ure's "Dictionary of Arts, Manufactures, and Mines," Lippincott's "Encyclopædia of Chemistry," Roscoe and Schorlemmer's "Treatise on Chemistry," &c. A complete set of the CHEMICAL NEWS, of London, from its beginning up to the present date, is one of the few "treasures" in the book case. In all there are, perhaps, some hundred and fifty volumes, but as the laboratory grows the number of books will increase, so that the nucleus at present formed may become, in time, a valuable part of the laboratory.

NOTE ON THE REDUCTION OF FERRIC SOLUTIONS BY THE USE OF AMALGAMATED ZINC AND PLATINUM FOIL.*

By ALFRED L. BEEBE, School of Mines, New York City.

IN the determination of iron in sulphuric acid solution by titration with potassium permanganate, amalgamated zinc and platinum foil are very generally employed to reduce the iron to the ferrous state. As ordinarily employed, their use for this purpose is frequently attended with two practical difficulties. The first is the amalgamation of the platinum strip through its contact with the zinc, and the consequent cessation of all reducing action. The second is encountered in transferring the solution from the reducing-bottle to the beaker in which the titration is to be made. Unless great care is exercised in this operation the zinc will fall into the beaker, fracturing it, and causing the loss of the analysis.

The following simple modification of the usual method has been found by the writer to obviate entirely the difficulties above referred to. A strip of thin platinum foil about one inch square is perforated with pin-holes over its entire surface. It is then bent into the shape of a letter U, and its opposite corners are connected by short pieces of platinum wire, so as to form a sort of basket. In this is placed a piece of amalgamated zinc of convenient size, and the whole is suspended by a stout platinum or silver wire in the bottle containing the solution to be reduced. Another strip of platinum foil, about 1½" × 2½" in size, is then dropped into the bottle in such a way as to lean against the wire supporting the basket and zinc without coming into contact with the latter.

Galvanic action at once commences and hydrogen is evolved in abundance from the surface of the foil, which never becomes amalgamated, as it comes into indirect contact only with the zinc.

When the reduction is complete the platinum basket containing the zinc is removed from the solution, washed in the titrating beaker, and laid aside, all danger of fracturing the beaker being thus avoided.

A LECTURE EXPERIMENT FOR SHOWING THE COMPOSITION BY VOLUME OF NITROUS AND NITRIC OXIDES.*

By E. H. KEISER.

THE usual method of showing that nitrous oxide contains its own volume of nitrogen, and that nitric oxide contains half its volume of nitrogen, is to decompose these gases by bringing them in contact with heated potassium. For this purpose a quantity of the gas to be examined is collected in a eudiometer over mercury, and its volume is determined. The gas is then transferred to a bent glass tube closed at one end, and a small piece of potassium is introduced into the bent portion of the tube by passing it up through the mercury by means of a wire. The lower and open end of the tube is now closed under the mercury with the finger, and the part of the tube containing the potassium is heated with the lamp. After the combustion the tube is allowed to cool. The gas, which now consists of nitrogen, is transferred back again to the eudiometer, and its volume is determined. To perform this experiment successfully, considerable skill in the manipulation of gases is necessary, and it requires so much time that it is not adapted to the purposes of the lecture table.

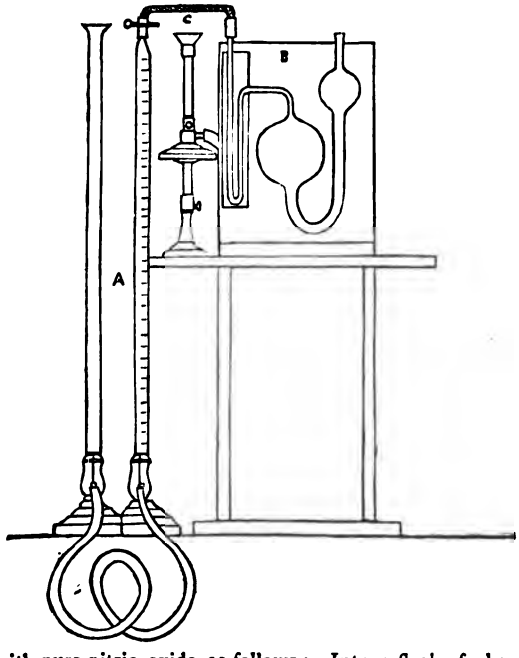
The same object may be attained much more easily and rapidly by means of the simple apparatus shown in the cut. It is based upon the fact that heated metallic copper combines with all the oxygen of the nitrogen oxides and sets the nitrogen free. The method of using the apparatus is very simple, and requires but little explanation. A represents a gas burette for measuring the volumes of the gases. B is a gas pipette, which is filled with water. The connecting-tube, C, is made of hard glass, and is 3 m.m. internal diameter, and from 10 to 12 c.m. long. It is completely filled with granular metallic copper, which has been obtained by the reduction of the granular oxide in a current of hydrogen. The copper is held in place by plugs of asbestos in each end of the tube. To decompose the oxides of nitrogen, this tube is heated to a red-heat with a Bunsen burner, and, to prevent it from bending,

* *American Chemical Journal*, vol. viii., No. 2.

a piece of wire gauze is wrapped around the outside and secured by wires.

A measured quantity of nitrous or nitric oxide contained in the burette A is passed over the heated copper by opening the pinch-cock and raising the reservoir tube of the burette. When the reservoir tube is lowered, the gas is drawn back from the pipette. It now consists of nitrogen, and its volume may be readily determined. If nitric oxide has been used, the volume of nitrogen obtained will be exactly one-half the original volume of the gas, while in the case of nitrous oxide the volume of nitrogen will be the same as the volume of nitrous oxide taken, although the copper will have been oxidised and the gas will have lost its power of supporting combustion. The error rarely exceeds 0·1 per cent in the case of nitric oxide, while with nitrous oxide equally good results are obtained if the water in the burette has been previously saturated with the gas.

It is of course necessary to have the oxides of nitrogen free from air. The burette may be conveniently filled



with pure nitric oxide as follows:—Into a flask of about 300 c.c. capacity there is placed a mixture of 100 grms. of ferrous sulphate and 12 grms. of potassium nitrate. To this is added a quantity of dilute sulphuric acid, obtained by mixing 60 c.c. of the concentrated acid with 160 c.c. of water. The flask is closed with a one-hole rubber stopper, through which passes a glass tube bent at right angles. On heating the mixture contained in the flask pure nitric acid is evolved. A T tube is then attached to the gas burette, and one of its branches is connected with the outlet tube of the flask. The air in the burette is expelled by opening the pinch-cock and raising the reservoir tube until water flows out of the open end of the T tube. After all the air has been expelled from the generating flask the open end of the T tube is closed with a rubber tube and pinch-cock, and the gas allowed to pass into the burette.

The same apparatus serves for filling the burette with nitrous oxide, the gas in this case being made by heating pure ammonium nitrate.

Condensation of Pyridin.—C. F. Roth.—The author has obtained a dipyridil which requires further examination.—*Ber. der Deutsch. Chem. Gesell.*

PROCEEDINGS OF SOCIETIES.

PHYSICAL SOCIETY.

May 22nd, 1886.

Prof. Balfour Stewart, President, in the Chair.

The following were elected Members of the Society:—Messrs. C. A. Bell, E. C. Johnson, and James Swinburne.

The following communications were read:—

"*On the Sympathetic Vibrations of Jets.*" By Mr. Chichester A. Bell.

It has been assumed hitherto that a gaseous or liquid jet vibrates under the influence of a limited range of tones only, effective tones being those which do not differ greatly in pitch from the normal or proper tone of the jet discovered by Savart and Sondhauss. The author has found, however, that when the pressure under which a jet escapes is not too great, the latter is affected by all tones lower than the normal, as well as by some above it. Changes may be excited in a jet of either kind by vibratory motions of the jet orifice, or of the fluid behind, or external to the orifice. These changes take the form of slight swellings and contractions, which become more pronounced as the fluid travels away from the orifice, and finally cause the jet to break or become discontinuous at a distance which depends upon the intensity of the initial disturbances. At any point within the continuous portion of the jet the successive swellings and expansions represent both the form and the relative intensities of vibrations impressed upon the orifice; and the jet is therefore capable of reproducing very complex sounds, such as those of speech and music.

A vibrating jet of air does not, however, emit sound when it plays into the air, or into the wide end of a tube communicating with the ear; but when it plays against a very *small* orifice in the end of a hearing-tube, loud sounds may result. This reproduction is most intense when the hearing orifice is placed in the axis of the jet, just within the breaking point, but becomes gradually feebler as the hearing orifice is moved towards the jet orifice, or out of the line of its axis. Beyond the breaking point the sounds from the jet at first become confused, and finally are lost.

A jet of gas, like a liquid jet, only vibrates so as to produce its normal tone when it strikes upon some obstacle which serves to diffuse the disturbances due to impact, or throw them back upon the orifice. The vibrations of an air jet are also loudly reproduced as sound, when it is directed against a small flame below the apex of the blue zone.

Liquid jets are but slightly sensitive to aërial sound impulses, but become highly sensitive when the jet tube is rigidly attached to a sound-board. The vibrations of a jet so mounted are best perceived as sound when the stream strikes upon a rubber membrane tied over the end of a narrow tube which communicates with the ear. For accurate reproduction of speech and sounds in general, the jet should be at such a pressure as to respond visibly to a note of about 4000 vibrations per second, and the membrane should be at such a distance from the orifice that the jet never breaks or becomes discontinuous above its surface.

The vibrations of very fine jets of any conducting liquid become loudly audible when a portion of the jet or the "nappe" formed, when it strikes upon a flat surface, is included in circuit with a battery and a telephone. This may be accomplished by letting the jet impinge on the end of an ebonite rod, through the centre of which passes a platinum wire: the upper end of the rod is surrounded by a short tube or ring of platinum, the upper margin of which forms a continuous, slightly convex surface with

the exposed end of the central wire and the ebonite. The wire and ring form the terminals of the circuit which is completed through the nappe. Distilled water, containing 1-300th of its volume of pure sulphuric acid, is recommended as the jet liquid.

The author advances a new theory to account for the growth of the vibratory changes in liquid and gaseous jets.

"*On some Thermo-dynamical Relations.*" Part V. By Prof. W. RAMSAY and Dr. S. YOUNG.

In Parts I. and II. of this series of papers it was shown that the ratio of the absolute temperatures of any two bodies corresponding to a given vapour-pressure bears a simple relation to the ratio at any other pressure, which may be expressed by the equation $R' = R + c(t' - t)$, where R' and R are the two ratios, c is a constant, and t' and t are the temperatures of one of the two bodies. The determination by Schumann (*Pogg. Ann. N. F.*, xii., 46) of the vapours of methyl formate and twenty-seven homologous ethers made it possible to compare the vapour-pressures of a large number of bodies belonging to the same class. It was found that when the ethers were compared with ethyl acetate, which was taken as the standard, in every case $c = o$, and therefore $R' = R$. The temperatures corresponding to the then pressures, 200, 760, and 1300 m.m., are given by Schumann. Taking the mean value of R for those pressures as correct, and re-calculating the temperatures, the greatest difference between the found and re-calculated temperatures is 0·7° C. The vapour-pressures of water, or any one of the ethers, being accurately known, it is sufficient to determine the boiling-point of any ether belonging to this class in order to construct its vapour-pressure curve. The absolute temperatures corresponding to the pressures 200 and 1300 m.m. for any ether are $0{\cdot}89795\ t$ and $1{\cdot}0488\ t$, where t is the boiling-point at normal pressure in absolute temperature.

A gridiron slide rule, by Mr. Stanley, designed by Mr. Thacher, was explained by Mr. C. V. Boys. It was equivalent to a slide 60 feet long, and performed multiplication and division with an error not exceeding the 1-40,000th part.

Specimens of safety explosives, and their results in shattering blocks of lead, were exhibited by H. Sprengel.

Prof. W. C. WILLIAMSON, LL.D., F.R.S., President, in the chair.

"*Preliminary Note on a New Method of rapidly determining the total Organic Carbon in Waters.*" By CHARLES A. BURGHARDT, Ph.D.

Hitherto all the methods recommended for water analysis, and particularly those which are most generally adopted by chemists, have failed to give the *total* organic carbon present in a polluted water. The method known as Frankland's is the principal one which has hitherto claimed to actually ascertain the amount of organic carbon and nitrogen in a water. This process of Frankland's necessitates a preliminary evaporation of the water to dryness, and I have no hesitation in saying that on this account it cannot any longer be relied on to give, even approximately, the amount of organic carbon present in a polluted water, because I have found in the course of numerous analyses of the water of the River Irwell and its tributaries, that a very large quantity of the organic matter in such polluted water exists in such a condition that a rise in the temperature to 100° C. caused it to decompose and be evolved in the form of carbon dioxide gas; consequently, during the evaporation to dryness, as in most methods of water analysis, this organic matter is lost and not taken into account at all. There is no doubt that in highly polluted streams the amount of carbon dioxide gas *in solution* is an index to the amount of pollution by sewage and manufacturers waste-waters. The water of the River Irwell is almost *saturated* with carbon dioxide gas at the temperature of the air. I have often proved that this carbon dioxide gas must be derived from the organic matters in the water, by determining the amount of *dissolved* carbon dioxide in a sample, and then keeping the same sample for several weeks, and ascertaining how much of the gas was dissolved in it, at intervals of a week, with the same result in all cases, viz:—*a further increase in the amount of carbon dioxide gas dissolved in the water.* This proves that the organic matter is easily decomposed into gaseous products; consequently it becomes a great difficulty how to ascertain the total organic carbon in a sample of polluted water.

About August, 1884, I first applied a slight modification of Ulgren's well-known method for determining the amount of carbon in steel, to water analysis.

The process is as follows:

Take an eight oz. or twelve oz. flask, fitted with a syphon funnel tube passing to the bottom of the flask, a thermometer, and an exit tube passing out of the flask into the bottom of a 4 oz. flask containing 50 c.c. of a standard solution of calcium hydrate, and an exit tube from this last flask passing to the bottom of another 4 oz. flask, also containing 50 c.c. of calcium hydrate solution. The exit tube from this last flask is connected with a small tube containing small pieces of caustic soda, to absorb any carbon dioxide gas which might otherwise get into the calcium hydrate flask from the air.

Place in the large flask 250 c.c. of the water sample, connect all the flasks, and fill partially the funnel tube with water, so that the pressure of the air at the end of the apparatus is overcome, and sucking back prevented. Now surround the flask with a water-bath, and heat the water in the flask to about 94° C., when the dissolved carbon dioxide is at once evolved and absorbed by the standard calcium hydrate solution in the small flasks. In a quarter of an hour or so these flasks are detached, the water-bath removed from the large flask, and the excess of calcium hydrate remaining in the flasks determined by titration with decinormal oxalic acid solution (using aurine as an indicator). The small flasks are then cleaned out and re-charged with the known volume of calcium hydrate solution as before, and the large flask containing the water heated by the bare flame of an ordinary Bunsen lamp, and the contents boiled until the steam—passing into the first small flask—heated the same to nearly boiling-point; at this stage the small flasks are disconnected, and the lamp removed from the large flask, the titration of the calcium hydrate in the flasks being repeated, ahd the amount of carbon dioxide thus evolved by the *decomposition of the organic matter* determined. Dilute sulphuric acid (about 20 c.c.) is now poured into the funnel tube and so into the large flask, the small flasks re-charged with calcium hydrate and connected to the large flask as before, and the latter again boiled with the bare flame of the lamp as in the last determination. The carbon dioxide obtained in this stage is mostly that derived from carbonates of calcium and magnesium in the water. I now take 5 grms. of crystallised chromic acid, or an equivalent amount of potassium bichromate, and dissolve it in 20 c.c. of strong sulphuric acid, and pour this mixture through the funnel tube into the flask, and repeat the operations as before. *The carbon dioxide evolved in this stage is derived entirely from organic carbon* present in the water.

I have tested this method with the Irwell water and obtained as much as 2·7 grains per gallon of carbon in the last stage, and 0·4118 grains of carbon altogether in the first and second stages. I have also tried it with a known weight of perfectly pure sugar, and obtained almost absolutely the theoretical amount of carbon. I hope to pub-

lish at an early date some of the analytical results obtained, and give at the same time comparative analyses by Wanklyn's and Tidy's methods. Until quite lately I have not been able to work out the process described above to a satisfactory termination.

Ordinary Meeting, March 9, 1886.

Prof. W. C. WILLIAMSON, LL.D., F.R.S., President, in the chair.

"*Note on Apparatus for Photographing the Moon.*" By A. BROTHERS, F.R.A.S.

About twenty years ago I read before the Photographic Section of this Society a paper on *Celestial Photography*. The paper contains a description of a piece of apparatus which I contrived and adapted to a telescope, so as to dispense with a camera in photographing the moon or other celestial objects. As I have recently been asked by Mr. E. G. Loder to obtain for him one of these instruments, and as there are some improvements introduced, and probably no member present has seen the apparatus, I have brought it for inspection.

When the eyepiece of a telescope is removed the image of the moon can be brought to a focus on a piece of ground glass in the same way as in an ordinary camera, and a picture could be taken on a plate held in that position. But as the process of taking single pictures is tedious, and as the area of the plate covered by the image is limited, it is possible to take four or more pictures on one plate. This little piece of apparatus is arranged for taking four pictures on a 5×4 plate. The great advantage of this plan of proceeding is that four different exposures may be obtained in very little more time than is required to take one; and this is important, as it enables the operator to select the one which appears nearest to being correct as a guide for subsequent work on the same evening.

With all telescopes, excepting reflectors, there is the difficulty of the chemical focus to overcome, and many failures arise in correcting this.

The only advantage in using a telescope in photographing the moon is that the length of focus gives a large image; but for photographing the stars the field is too limited, and the time of exposure is of course long. It was in order to obtain a large field that I used a camera and photographic lens in photographing the eclipse in 1870. This method has been followed on every occasion of an eclipse since; and I am glad to notice that in the very important work now being carried on in various observatories for photographing the stars the same plan is adopted. The introduction of gelatin plates has greatly facilitated the work of photographing the stars and other faint objects, but so far as my own observation extends the whole of the best eclipse work and the photographs of the moon have been done by the old collodion process.

Ordinary Meeting, March 23, 1886.

Prof. W. C. WILLIAMSON, LL.D., F.R.S., President, in the chair.

"*On the Determination of the Calorific Power of Fuel by Direct Combustion in Oxygen.*" By WILLIAM THOMSON, F.R.S. Ed., F.C.S.

Having been engaged some time ago with determinations of the heating power of various samples of coal by the apparatus devised by Mr. Lewis Thompson, M.R.C.S., I was struck by the unsatisfactory nature of the process, which consists in mixing intimately 2 grms. of coal with 22 grms. of a mixture of 3 parts of chlorate and 1 part of nitrate of potash. This mixture is placed in a small copper tube, and ignited by a fuse prepared by soaking two or three strands of ordinary lamp wick in nitrate of potash solution and drying. About three-quarters of an inch of this fuse is placed upright in the mixture, the tube containing which is put on a stand, surrounded with four upright brass springs (strips of brass fixed to the stand at the bottom and curved upwards and inwards).

The fuse is ignited, and smoulders slowly down to the coal and oxygen mixture. In the meantime a cap or cylinder of copper closed at the top (to which is attached a narrow copper tube furnished at the end with a stop-cock) is placed over the copper tube containing the coal, chlorate, and nitrate mixture by pushing it over the springs which serve to keep the copper cylinder in its place. The whole apparatus is now lifted by the narrow copper tube and immersed in a glass cylinder about 13¼ in. long by 4½ in. wide containing a large quantity of water (preferably either 2000 or 1934 c.c.), the temperature of which has been accurately taken by a delicate thermometer. The mixture ignites and burns away like a squib, the hot gases bubbling through the water, to which it parts with its heat. When the combustion is complete the stop-cock at the end of the narrow copper tube is opened to allow the residual gas in the apparatus to escape and to allow the water to take up the heat still retained by the copper tube and by the salts left from the combustion. It is admitted that even with the most careful use of this apparatus it is impossible to obtain accurate results, because there are so many sources of error. First, the chlorate of potash in becoming dissociated into chloride of potassium and oxygen liberates a considerable quantity of heat; the nitrate of potash, on being decomposed, absorbs heat; the oxygen, on being liberated from the solid condition and expanding to the ordinary pressure of the air, absorbs heat; and there is a further error introduced by the combustion of the copper of the tube—the tube, becoming heated to bright redness, becomes covered with a scale of the oxide; and, last of all, the potassium chloride remaining from the combustion absorbs a considerable quantity of heat in dissolving. Mr. Lewis Thompson recognised that his process did not register the total quantity of heat produced, and he says it is necessary to add 10 per cent to the result obtained. According to Mr. Thomas's experiments, if the coal be of a graphitic nature the chlorate and nitrate mixture will not burn it completely; yet the process is employed by the Italian Government as a test, and by railway and other companies in England. I have further found it difficult to obtain concordant results from this process with the same coal tested at different times.

The process which I have devised consists in burning the coal in oxygen. In a short communication which I brought before the Physical and Mathematical Section of this Society on the unsatisfactory nature of Lewis Thompson's process, our excellent Vice-President, Dr. Joule, suggested the idea to me of burning the coal in pure oxygen. I endeavoured to accomplish this in many different ways, but failed, a certain amount of unconsumed carbon, under some conditions, being liberated which adhered to the sides of the vessel containing the oxygen, whilst under other conditions the carbon consumed very slowly and usually imperfectly, leaving some unconsumed carbon behind. I ultimately succeeded in completely consuming the coal within a few minutes, and measuring the heat produced therefrom by the apparatus and method which I give, as follows.

I took the ordinary stand, with brass springs attached, which was used for the Lewis Thompson apparatus. In it I fitted the bowl of an ordinary clay tobacco pipe, rather less than ¼ in. internal diameter by 1½ in. long. This I used as a stand for a small platinum crucible ¼ in. diameter by 1½ in. long, because the clay is a non-conductor of heat and would not injure the platinum, when heated to redness. Into this platinum crucible I introduced 1 grm. of coal in a fine state of division, which was ignited, after being placed on its stand, by a fuse such as that used by Mr. Lewis Thompson, and the whole covered by an inverted wide glass test-tube 6 in. long by 1½ in. diameter, to the bottom of which was

attached a piece of narrow tubing 1 in. long by ⅛ in. in diameter. Over this tube was drawn a piece of india-rubber tubing, the free end of which was turned over on itself, and through this rubber was passed a glass or thin copper tube (preferably the latter) terminating with a stop-cock.

When the fuse is ignited the mouth of the test-tube is pushed over the brass springs, thus enclosing the platinum crucible containing the coal, on the diving-bell principle, and the whole is then sunk into the cylinder, containing either 1934 or 2000 grms. of water, the temperature of which has previously been taken by a delicate thermometer. A stream of oxygen from a gas holder or gas bag is then allowed to flow slowly through the test-tube downwards, making its escape at the mouth and bubbling through the water. It is necessary to commence the combustion by having the movable tube which penetrates the bottom of the test-tube drawn well up so as to have a complete atmosphere of oxygen in the test-tube until most of the volatile matter of the coal is consumed. The movable tube is then gradually pushed down till it comes to the mouth of the platinum crucible; a slow circular movement is then given to it by the hand till the whole of the fixed carbon of the coal is consumed, which is rapidly done under the stream of oxygen impinging on it. The ash is then left as a number of fused globules, many of them adhering to the crucible, having been completely fused by the intense heat of the combustion. The water is then allowed to enter the tube and come in contact with the hot crucible and tobacco-pipe support and entrance tube for the gas, to abstract the heat left in them; the whole of the water is then well mixed and the temperature again taken, the difference between the two temperatures being the heat given to the water by the combustion of the coal. I have found that the temperature of the water is practically not altered by passing about three gallons of air or oxygen through it, that being in excess of the quantity required to burn the coal, between 1½ and 2 gallons being actually required.

By this method it is not necessary to deduct or add to the result obtained. It is more convenient than Lewis Thompson's method, inasmuch as it is not necessary to have the coal in such a fine state of division, whilst the drying and weighing out of the nitrate and chlorate of potash, and incorporating the coal with them, is dispensed with, and when care is taken the results obtained by a series of experiments on the same coal is the same for each experiment. The rise for each grm. of good coal is somewhere about 6 to 7 degress Fahrenheit for the 1934 grms. of water, that being equivalent to about 11,500 to 13,500 units of heat.

Graphite burns away quite easily in the oxygen apparatus.

During the time the experiment is being made I find it necessary to have the cylinder containing the water resting on three pieces of cork in a loosely fitting vessel of bright tinned iron plate, having a slit 7 in. long and 1 in. wide cut down one side, through which the combustion can be observed. This vessel practically prevents loss of heat from the water if it is above the temperature of the surrounding air, and *vice versâ* if the temperature of the water be lower than that of the air, but I prefer to have at hand a large supply of water which has been exposed to the atmosphere for some hours, in order that its temperature may become as nearly as possible the same as that of the air.

Certain Double Silicates of Aluminium and Potassium or Sodium.—Al. Gorgen.—The author has examined the action of kaolin upon the alkaline haloid salts, upon alkaline carbonates, and caustic alkalies. The results obtained with the caustic or carbonated alkalies explain in what manner these reagents act upon aluminium silicates, transforming them into a mixture of silicate, aluminate, and double salts.—*Comptes Rendus.*

NOTICES OF BOOKS.

Notes on Analytical Chemistry for Students in Medicine. Extracted from the Fifth Edition of "Notes for Students in Chemistry." By A. J. Bernays, Ph.D., F.C.S., F.I.C. London: J. and A. Churchill.

The author tells us, in his Preface, that in remodelling the sixth edition of his "Notes for Students in Chemistry," want of space compelled him to eliminate the "Notes on Analysis," which had previously formed part and parcel of that work. He accordingly published them independently in 1879, and he now places before the public a second and extended edition.

We learn further, from the Preface, that the object of this work is essentially examinational. The author "trusts and believes that these analytical notes will be suitable for students at all ordinary examinations." In other words, Dr. Bernays' chief concern is to enable students to "pass,"—certainly not the highest aim.

Conciseness of language has been carried to a very great length, though falling short of obscurity. We notice a few peculiar expressions: thus we read that certain substances "combust." In the section on volumetric operations we find the term deci-equivalent substituted for the familiar "decinormal."

We notice with satisfaction that Dr. Bernays considers the estimation of phosphates in waters as of great importance, and declares that "in a surface water they certainly point to sewage contamination." The presence of potassium salts in water he also regards as a bad sign. Generally speaking, we certainly should agree with him in both these conclusions; still, surface waters draining from lands which have been manured with superphosphate, especially if calcareous matter be deficient, may contain an appreciable quantity of phosphoric acid in the entire absence of sewage contamination. Potassium salts may, in a corresponding manner, be introduced into surface waters by means of kainite, which is now somewhat widely used as a manure.

The author, very justifiably, dissents from the view that nitrates present in water necessarily indicate previous sewage contamination, since they may be geological in their origin.

The section on ultimate organic analysis is far too brief to be of any practical value.

In the notice of the "periodic law" we are very glad to perceive that due honour is given to Mr. Newlands.

There are certain omissions perceptible in the work before us, but, considering how much matter has had to be compressed within some one hundred and twenty pages, the wonder is rather that they are not more numerous.

Notes on the Corrosion of Iron and Steel, and Means adopted for their Preservation and Protection, with Special Reference to the Protection of Iron and Steel Ships. By T. H. Davis, F.I.C. Liverpool: Tyerman.

This pamphlet deals with a question of very great importance to our country. An immense yearly loss is experienced, both in the Royal Navy and the Mercantile Marine, from this one cause, corrosion, or, chemically speaking, oxidation. This oxidation, as theory would inform us, and as actual experience, here quoted, shows, goes on the more rapidly the higher the quality of the iron.

We learn, from the report of Lloyd's chief engineering surveyor, that "the rate of corrosion of high-class Yorkshire plates amounts to 9·4 per cent more than common iron, and *mild steel 40 per cent more.*"

In painting, as an antidote to corrosion, the author has little faith—at least as it is commonly practised. He suggests that the oil used, generally linseed oil, is not a protective, but very probably assists the rapidity of oxidation. This we shall think the more likely if we reflect

that most of the oils of commerce contain a noteworthy proportion of free fatty acids. Caustic alkali, the author admits, suspends the corrosion, but how is an alkali applied to a ship's bottom to be kept at once from washing off and from taking up carbonic acid from the sea-water?

Mr. Davis goes on to show that no trustworthy coating has yet been invented, or else that the conditions in different seas vary, so that what is useful in one part of the world may be elsewhere useless or even hurtful. Against red-lead paint he protests on good grounds. Iron when in contact with lead is rapidly destroyed. Besides, the men in large dockyards, who are frequently employed in scraping lead paints off vessels and re-painting them, suffer severely from lead-poisoning.

The author thinks that black varnish or boiled coal-tar, if freed from ammonia and sulphuretted hydrogen, "approach very nearly the typical paint for iron-work."

We may here raise the question whether a paint made from red oxide of iron would not at least be much preferable to red lead? We know that such iron-paint has been successfully used for the hoops of casks in which iron mordants, such as black liquor and nitrate of iron, are stored up or sent out.

Of the anti-fouling paints, which are to prevent the adhesion of barnacles and sea-weeds by means of some poisonous mineral salt, he forms but low estimate. The organisms in question are found in quantity adhering to compounds of this character. Besides, the salts of arsenic, antimony, and mercury employed are often decomposed and the metals deposited on the iron, setting up destructive galvanic actions.

The conclusion arrived at is conveyed in the words—"Let ship-owners insist on the best of cleaning and painting, using their best judgment and care in choice of the composition to be employed, inclining to those which dry with a smooth, hard surface, depending on a scientific anti-fouling property, and containing no decomposable mineral poisons."

It is to be hoped—and such is evidently the author's wish—that this subject may attract study and research. The misfortune is that private firms and companies, just like governments, have their "circumlocution offices," and insist on seeing with the eyes of some interested official. Thus invention is discouraged.

Report by Prof. Wrightson and Dr. Munro, of the College of Agriculture, Downton, Salisbury, on Experiments made by them to Test the Manurial Value of the Basic Cinder made at the Works of the North-Eastern Steel Company, Limited, Middlesborough. Middlesborough: "Daily Exchange" Office.

Among the results of the Thomas-Gilchrist process not the least important is that a very large quantity of phosphoric acid, formerly neglected, is made available as plant-food. The cinder or slag actually used contained 14·32 per cent of phosphoric acid, though the North-Eastern Steel Company are now producing a cinder containing 16 to 19 per cent of phosphoric acid.

The cinder, finely ground, was tried against ordinary superphosphate, containing 26 to 28 per cent soluble phosphate, against a rich Curaçoa superphosphate containing 44 to 45 per cent soluble phosphate, and ground Cambridge coprolites containing 55 per cent tricalcic phosphate. The experiments were made at Downton on a light, thin, chalky soil, and at Ferryhill, Durham, on a stiff deep clay which was almost destitute of lime.

The result showed that the raw, ground basic cinder has a very considerable manurial value, and that it pushes on the young turnip and Swede plants beyond the reach of their enemy, the "fly." An average dressing of ½ ton cinder per acre more than doubled the crop at Downton, as compared with the adjacent unmanured plots, and more than quadrupled it at Ferryhill.

It is remarkable that ground cinder containing 14·3 per cent of phosphoric acid gave better results than an equal weight of ground coprolites containing 25 per cent of phosphoric acid. Hence the authors draw the very natural conclusion that the phosphate in the cinder is in a more assimilable condition than that in coprolites.

The phosphoric acid in cinder is, however, not so easily assimilated as that in soluble phosphates, the difference being less in this respect on the clay than on the chalk.

Various mixtures of raw cinder and superphosphate have been tried and patented. The cinder is specially recommended as a "drier" for superphosphates, and as a precipitating agent for the phosphoric acid of superphosphate.

A kind of superphosphate, "ferrous superphosphate," made from basic cinder and patented, has also been tried.

On the clay soil the authors consider that the best dressing is 4 cwts. raw ground cinder per acre, whilst at Downton the best proportions range from 10 to 20 cwts. per acre.

This pamphlet must be regarded as a valuable contribution to agricultural chemistry.

CHEMICAL NOTICES FROM FOREIGN SOURCES.

Note.—All degrees of temperature are Centigrade unless otherwise expressed.

Comptes Rendus Hebdomadaires des Séances, de l'Académie des Sciences. Vol. cii., No. 20, May 17, 1886.

Observations relative to the Determination of Ammonia in the Soil; a Reply to M. Schlœsing.—MM. Berthelot and André.—The authors do not contest the experiments of M. Schlœsing, but they do not consider that these prove the absorption of ammonia by the soil from the atmosphere. They show merely a progressive enrichment in ammonia of a dry earth exposed to the contact of the air during the months of August and September, whilst moist earth retains very little. But they throw no certain light on the origin of this ammonia. They recommend that the ammonia of a soil should be determined immediately after the sample is taken, and without previous drying.

Atomic Volume of Oxygen.—E. H. Amagat.—Referring to M. Wroblewski's announcement that the atomic volume of oxygen is decidedly inferior to 16, the author points out that in his communication of March 2, 1885, he drew the same conclusion from his experiments. Under a pressure exceeding 4000 atmospheres he succeeded in obtaining oxygen with a density exceeding 1·25 at the temperature of 17°. M. Wroblewski by refrigeration alone has succeeded in obtaining for the same body at −200° a density equal to 1·24. It is probable that by combining the action of cold and pressure we might arrive at a much higher figure, and consequently at a lower atomic volume. In this case we might admit, with Dumas, that sulphur, selenium, and tellurium may have the same atomic volume, whilst that of oxygen (which, moreover, occupies a separate position in this family) would bear a simple relation with the other three, probably as 1 : 2. In these conditions the form which the branch of L. Meyer's curve would take indicates for fluorine an atomic volume the half of those of chlorine, bromine, and iodine.

Action of Vanadic Acid upon Ammoniacal Salts.—A. Ditte.—Ammoniacal salts brought in contact with vanadic acid may act in three different manners: 1. Vanadic acid is capable of uniting with the salt in question,

forming the ammoniacal salt of a complex acid; 2. The vanadic acid decomposes the ammoniacal salt, forming an acid salt and an acid ammonium vanadiate, always a trivanadiate on operating at a boil; 3. Lastly, vanadic acid is without action upon the ammoniacal salt, as in the case of ammonium nitrate.

Combinations of Zinc Chloride with Water.—R. Engel.—The author describes three compounds, the first containing 3, the second 2 mols. of water, whilst the third contains 2 mols. of zinc chloride to 3 of water.

Compound of Hydrogen Phosphide with Chloral Hydrate.—J. de Girard.—The author has previously obtained dichloral-phosphine, a compound consisting of 1 mol. hydrogen phosphide combined with 2 mols. anhydrous chloral. He has now succeeded in preparing a corresponding compound with chloral hydrate, and has examined some of its derivatives.

On Pilocarpine.—E. Hardy and G. Calmels.—The authors have established the constitution of this compound and have examined its derivative, pilocarpidine.

Researches on the Composition of Carotine, its Chemical Function, and its Formula.—A. Arnaud.—Carotine is rapidly oxidised by the air even at the ordinary temperature, and especially about 70°. During this change the blue solution of carotine passes into a violet and finally into a brick-red. The oxidised product contains 21 per cent of oxygen, and does not possess the properties of carotine. It is incapable of crystallisation. Carotine is a non-saturated hydrocarbon.

Journal de Pharmacie et de Chemie.
Series 6, Vol. xiii., No. 8, April 15, 1886.

The Ptomaines and the Leucomaines.—(Continued).—Armand Gautier.—In this paper the author describes the muscular leucomaines, xanthocreatinine, crusocreatinine, amphicreatinine, and pseudoxanthine. In summing up his results the author adds that along with the animal alkaloids there exist other nitrogenous substances which are not alkaloids, but which have a still greater activity. The septic poison of panum contains no alkaloids; the nitrogenous matters extracted from urine are highly toxical, and the author is convinced that the essentially active portion of serpent poisons, though nitrogenous, is not alkaloidal.

A Ptomaine extracted from Poisonous Cheese.—V. Vaughan.—The poison in question, turotoxicon, forms acicular crystals. It reduces iodic acid and does not precipitate the ordinary reagents for alkaloids. If exposed to the air the crystals are destroyed, leaving an acid product. They are soluble in water, alcohol, and ether.

Electrolytic Determination of Mercury.—Don Luis de la Escosura.—(See p. 249).

Presence of Roccelline Red in Saffron.—MM. Cazeneuve and G. Linossier.—The authors detect this fraud by comparative dyeing experiments. They consider that roccelline red is less dangerous than jaune d'or (sodium binitronaphthol) and sodium dinitrocresylate.

Essential Oils of the Aurantiaceæ.—Ch. Noel.

Potable Waters of Compiègne.—H. Priou.—The author has examined a number of specimens of well and river waters from the district of Compiègne, determining hardness, sulphuric acid, and lime, chlorine, oxygen, organic matter, organic nitrogen, and ammonia. Nitric nitrogen and phosphoric acid have not been determined. According to M. Marié-Davy (*Journal d'Hygiène*) the ammonia falls from 29·2 grms. in the sewage of Paris to 0·7 grm. in the drain of Asnières. The albumenoid ammonia falls in like manner from 2·8 grms. to 0·3 grm., whilst the nitric nitrogen rises from 1 grm. to 24·3 grms.

Poisonous Principles of Mussels.—M. Brieger.—The author has obtained from these molluscs, 1, a non-poisonous substance; 2, a substance which is isolated by means of platinum chloride, and which produces energetic salivation and diarrhœa; 3, the specific virus, which combines only with the tetrahedral platinum chloride. It possesses the characteristic properties of curare; 4, an analogous body, probably a decomposition-product. It is an energetic poison and occasions shiverings. The two last-mentioned bodies seem to be ptomaines. Non-poisonous mussels, if brought in from the offing and deposited in the harbour, become poisonous, but lose this property again if returned to the open sea. (Is the development of the poisonous principles occasioned by the mussels feeding upon sewage-matters?)

Therapeutic Use of Hydrated Zinc Sulphide.—Pierre Vigier.—This paper has no chemical interest.

Bulletin de la Société Chimique de Paris.
Vol. xlv., No. 9, May 5, 1886.

Density Pipette.—L. Amat.—This apparatus cannot be intelligibly described without the accompanying figure.

The Bitter Principles of the Hop.—H. Bungener.—The author rejects the common view that the resin of the hop-cones is the bitter principle. This resin is insoluble in water, but a decoction of hops made with distilled water is quite as bitter as a decoction of malt in which an equal quantity of hops has been boiled. M. Bungener shows that the crystalline acid, first obtained in an impure state by Lermer, is really the bitter principle. This lupulic acid is insoluble in water, but its oxidation-product dissolves rapidly in water, with the aid of heat, imparting to it an intensely bitter taste.

Action, in the Cold, of Alcoholic Chlorides upon Ammonia and Methylic Amines.—C. Vincent and J. Chappuis.—This paper requires the accompanying illustration.

A New Ureometer.—The construction and the use of this instrument cannot be rendered intelligible without the annexed cut.

On Some Xylenic Derivatives.—A. Colson and H. Gautier.—The authors describe the ortho-, para-, and meta-xylene perchlorides, the terephthalic, orthophthalic, and metaxylenic aldehydes, and orthophenylene-glyoxylic acid.

Action of Aluminium Chloride upon the α-Bromo-, Chloro-, and Iodo-naphthalines.—When aluminium chloride reacts upon α-monobromo-naphthaline there are produced naphthaline, α-monobromo-naphthaline, undecomposed β-monobromo-naphthaline, a small quantity of dibromo-naphthalines, and black tars which cannot be distilled. The same reagent, acting upon α-monochloro-naphthaline yields a small quantity of naphthaline, black tarry matters, and β-monochloro-naphthaline. With α-monoiodo-naphthaline the products are naphthalene, free iodine, and tars which cannot be distilled.

Berichte der Deutschen Chemischen Gesellschaft zu Berlin.
Vol. xix., No. 3.

Propyl Group in the Cumin and Cymol Series.—O. Widmann.—Isopropyl passes in the following cases into normal propyl; cuminic alcohol, on boiling with zinc-powder passes into ordinary cymol. Cumyl chloride, if boiled with zinc-powder and hydrochloric acid, yields ordinary cymol. Nitrocymylenchloride, on boiling with zinc and hydrochloric acid, passes into normal cymidine. On the other hand, normal propyl is converted into isopropyl in the following cases: ordinary normal cymol in passing through the animal organism is oxidised to cuminic acid; cymol is converted into cuminic acid on agitation with

soda-lye and air; normal cymol-sulphonic acid on oxidation with potassium permanganate in an alkaline solution, yields oxy-isopropyl-sulphobenzoic acid. Cymol, on heating with permanganate in a strongly alkaline solution, yields oxy-isopropyl-benzoic acid. Thymol, on fusion with potassium hydroxide, is converted into the same oxycuminic acid which Lippmann and Lange obtained by the action of nitrous acid upon meta-amidocuminic acid. Carvacrol, which contains normal propyl, passes, on fusion with potassium hydroxide, into an oxycuminic acid, probably the ortho-variety.

New Researches on Diazo-compounds.—(Twelfth communication).—P. Griess.—The author describes the decomposition of diazo-benzolimide with hydrochloric acid, the decomposition of the same compound with sulphuric acid, the decomposition of meta-diazobenzoic-imide with hydrochloric acid, chlor-amidobenzoic acid sparingly soluble in cold water, the modification more easily soluble in cold water, and, secondly, the action of nitrous acid upon aromatic diazo-compounds, including the meta-bidiazobenzol compounds, meta-tetrazobenzol platinum chloride hydrochlorate, and meta-tetrazobenzol-auric chloride hydrochlorate.

Applicability of Hydrogen Peroxide in Volumetric Analysis.—S. Eliasberg.

Electrolytic Quantitative Analysis. — A. Classen and R. Ludwig.—These two papers will be inserted at some length.

Coccerine from Living Cochineal.— C. Liebermann. —The author has had the opportunity of examining the peculiar wax of the cochineal of commerce as found on the unprepared living insect.

Synthesis of Oxy-anthraquinon from Meta-oxybenzoic Acids and Benzoic Acid.—C. Liebermann and St. von Kostanecki.—Both mono-oxy-anthraquinons are formed, but accompanied by three isomeric dioxy-anthraquinons. The separation of oxy-anthraquinon and benz-bioxy-anthraquinon is effected by means of their acetyl-compounds.

Synthesis of Xanthopurpurin and Purpurin.— E. Noah.—The author mixes 1 part symmetric dioxybenzoic acid, 5 parts benzoic acid, and 5 parts sulphuric acid. The mixture is heated to 105° to 110° in the oil-bath for seven hours. Xanthopurpurin is obtained from the mass by repeated extraction with ether. Xanthopurpurin is converted into purpurin by fusion with solid potassa and a little water.

Behaviour of Nitrised Acetanilides and Naphthalides with Alkali.—Kleemann.

Nitroso-naphthols and Certain of their Derivatives. —M. Ilinski.—These two extensive memoirs do not admit of useful abridgment.

On Dinitroso-naphthaline.—M. Ilinski.— This compound is insoluble in water, sparingly soluble in cold alcohol, hot ligroin, and ether, readily soluble in hot benzol, from which it is precipitated by ligroin in fine needles. The compound is readily volatile along with watery vapour, and it dissolves in strong sulphuric acid with a yellow colour.

Azopianic Acid and a New Derivative of Indigo. C. Liebermann.—On the nitration of opianic acid the nitro-group really assumes the ortho-position with reference to the aldehyd-group. The new compound is an indigo which contains the substituting groups of opianic acid.

Certain Reduction-Products of Aromatic Aldehyds.—Fr. Tiemann.—It appears that benzaldehyd on the one hand and salicylaldehyd and para-oxy-benzaldehyd on the other behave in an essentially different manner when treated with zinc powder and glacial acetic acid. The first mentioned is easily reduced to benzyl alcohol and then converted into benzyl-acetate. In the two latter the reduction extends only to the formation of hydrobenzoine-like substances.

Bulletin de la Société d'Encouragement pour l'Industrie Nationale. 4th Série. Vol. i., No. 3, March, 1886.

Purification of Ammonium Hydrochlorate.—This compound is one of the by-products extracted from the residual liquors of the ammonia-soda process, but it is always mixed with sodium chloride, which, as an impurity, reduces its value. M. Solvay separates the two products by evaporating the liquid to dryness and expelling the ammonium hydrochlorate by heating to the requisite temperature. The residual salt is then heated in a retort with the addition of some inert matter to distribute the heat more uniformly. Finally the ammonium hydrochlorate is volatilised by injecting a current of superheated steam.

NOTES AND QUERIES.

THE CHEMICAL NEWS.

Vol. LIII. No. 1385.

NOTE ON THE BLUE COLOURING-MATTER OF DECAYING WOOD.

By SAMUEL RIDEAL, B.SC., F.C.S.

The wood from which the colouring-matter experimented with has been extracted was found in the neighbourhood of Aviemore, Inverness-shire, in different parts of the forest of Rothiemurchus, but in most cases it was so decomposed and decayed as to render its identification difficult. One piece, however, was obtained with the bark attached, and with the blue colour well developed throughout the wood, which was easily recognised as being the wood of *Betula alba*. In the localities in which the specimens were found the birch tree was especially abundant, and no Coniferæ were observed in the immediate neighbourhood; so that, although the blue colour has not been found in the growing birch, there is good reason for believing that all the specimens collected were pieces of the decayed wood of this tree. Girdwood and Bemrose (*Brit. Assoc. Reports*, 1884) have shown, in some preliminary notes on a blue colouring-matter found in certain wood undergoing decomposition in the forests of Canada, that a similar colouring-matter is developed in the decaying wood of the balsam pine (*Abies balsamea*). All their specimens were found lying on the ground, and never in standing trees; and although they did not succeed in obtaining any specimens with the bark attached, yet, from the microscopical character of the wood, and from several knots and fragments of roots, they inferred that the wood must be that of the Canadian balsam. From the fact that the colouring-matter apparently begins to form in the sap-wood, and from its solubilities and insolubilities, they conclude that it may be a result of the decomposition of the balsam in the outer layer of the woody tissue. The formation of balsam appears not to be a function of the plant itself, but to be due to the action of atmospheric oxygen; and as the yellow or brown colour of most balsams darkens on exposure to the air, the blue colour may be one of the stable products of the oxidation.

Some botanists believe that this blue colour is the same as that produced in the well-known reaction of pine-wood with phenol and strong sulphuric acid. Tiemann and Haarmann showed that this was no doubt due to coniferin, since coniferin—when treated with sulphuric acid in varying proportion—strikes a violet colour changing to red, and when this solution is diluted with water a blue resin is deposited. Hartig found coniferin in *Larix Europæa*, and, according to Kupel, it exists in all "zapfenbaumen." Tiemann and Haarmann worked with the cambium layer of *Abies excelsa*, *A. pectinata*, *Pinus strobus*, *P. cembra*, as well as that of *Larix Europæa*. Lippman has also found it in beet-root and asparagus (*Ber.*, xviii., 3335); so that coniferin, as Singer has remarked, is far more general as a product of plant-life than is usually supposed.

The presence of coniferin in the two species of *Abies* above mentioned and the occurrence of the blue colour in *Abies balsamea* lead one to suppose that the conclusion that the blue colour is due to coniferin may be a correct one. Experiments were therefore tried on the blue colour from the birch tree, to determine whether it was identical with that found in the Canada balsam, or with that produced from coniferin, or with both.

The wood in which the blue colour was well developed was cut up fine and boiled with distilled water, giving a pale yellow solution, and then warmed with a mixture of alcohol and ether, which also yielded a solution of a pale yellow colour. The residue was finally extracted with chloroform, in which the blue colour is readily soluble, forming a fine blue solution. When the wood was treated with dilute potash a brown solution was obtained, which was turned blue by acids, and from which the colouring-matter could then be extracted with chloroform. Glacial acetic acid is also a good solvent for the pigment, and has the advantage of leaving undissolved the phlobaphene, the brown colouring-matter of the bark, which is abundant in the birch. This concentrated acetic acid solution is blue in colour, and is turned brown by potash, but the colour reappears on acidifying. When the chloroformic extract was evaporated, a blue non-crystalline mass was obtained, which was soluble in glacial acetic acid, but was turned brown on the addition of concentrated hydrochloric acid. The acetic acid solution, on warming or after standing for some time, loses its blue colour, so that after evaporating the greater part of the acetic acid a deep brown solution is obtained. This brown solution, on dilution with water, gave a brown precipitate, which was filtered off, washed, and dried. The solid was then insoluble in chloroform and carbon bisulphide, but was redissolved by glacial acetic acid, and apparently by potash and ammonia, yielding a yellow-brown solution. Nitrous acid, chlorine, and bromine gave no definite reaction with the body. The alkaline solution, on acidifying with hydrochloric or other mineral acid, gave a bright blue precipitate.

Reducing agents (*e.g.*, ammonium sulphide or stannous chloride) destroy the blue colour, but it can be reproduced by the cautious addition of nitric acid.

The chloroform solution was examined spectroscopically, and was found to give a faint, but definite, absorption-band in the yellow-red part of the spectrum, between the positions of the C and D lines. In this respect the blue colouring-matter of the birch differs from that obtained from the Canada balsam, since Girdwood and Bemrose obtained with it no special absorption-bands.

Through the kindness of Prof. Girdwood, who furnished me with a specimen of the Canadian colouring-matter, I have been enabled to compare its reactions with those above described, and from such examination it appeared evident that the colouring-matter of the birch did not present precisely the same characteristics as that derived from the Canada balsam.

To determine whether the blue colour was due to coniferin several specimens of birch-wood, in different stages of growth, were carefully tested for the presence of coniferin, but no trace of this glucoside could be found by the tests applied.

Some of the blue colouring-matter produced by the action of strong sulphuric acid upon coniferin, prepared from pine-wood, was prepared by precipitating the strongly acid solution with a large quantity of water. The blue colouring-matter is soluble in the stronger acids to a deep red solution; in weaker acids, such as acetic acid, to a blue solution; and the addition of potash or soda to these solutions gives a green colour. Stannous chloride in the cold has little reducing action on the acid solution. The solutions in acetic and sulphuric acids were examined by the spectroscope, and yielded absorption spectra which were different from that obtained from the blue colouring-matter of the woods examined. It was also completely insoluble in chloroform. It thus differs very considerably from the natural blue colouring-matters.

The amount of colouring-matter extracted from the wood was insufficient to allow of a complete analysis of it being made. It was, however, tested for nitrogen, and found to give with the sodium reaction only the merest trace of a cyanide, and when treated with soda-lime no ammonia was evolved. It seems therefore not to contain any nitrogen. When heated, it completely decomposed and left no ash, showing that the sample prepared contained no mineral matter.

From the above facts, then, it may be concluded that

the blue colouring-matter in decaying wood is not due to coniferin,—at any rate in some cases,—and that in all probability there are several different blue colouring-matters produced in this manner. These colouring-matters may be due to the action of organisms which flourish in an environment such as that presented by the damp and decaying underwood of dark forests, and so be classified with similar colours produced by chromogenous schizophytes in other kinds of organic matter undergoing decay.

ELECTROLYSIS OF MOLYBDENUM SOLUTIONS.

By EDGAR F. SMITH and W. S. HOSKINSON.

IN a paper published by one of us (S.) in the *American Chemical Journal*, vol. i., No. 5, attention was directed to the action of the electric current upon alkaline molybdic acid solutions. We there showed that although this method of precipitation was complete, yet the unusual time (100 hours) required rendered it practically useless. Since then we have found that by employing neutral solutions, or such as contain a very slight excess of sulphuric acid, quite satisfactory results can be obtained.

The form in which the molybdenum separates on the crucible sides is as black $Mo_2O_{33}H_2O$, as already observed (vol. i., No. 5). When the precipitation is complete the liquid is carefully syphoned off, the bright, compact coating washed with water, and the crucible with its deposit dried upon a water-bath (about 90°) and weighed. It may be well to carefully ignite the black oxide in a covered crucible and thus convert into trioxide, and weigh in the latter form.

In Volume 4 of the *Handwörterbuch der Chemie* it is stated that the electric current precipitates metallic molybdenum from solutions of ammonium molybdate. The determinations made by us under varying conditions do not confirm this statement. Our product in all instances was $Mo_2O_{33}H_2O$.

For our experiments we employed solutions containing different amounts of molybdenum. The precipitation was made in a platinum crucible of about 30 c.c. capacity, although the dilution rarely exceeded 25 c.c., so that space remained for exposure of fresh surface, and in this way afforded a ready means of knowing when the precipitation was complete. The filtrate and washings from the deposit were always examined for molybdenum. The deposition of oxide occurs upon the zinc pole of the battery.

Experiments.

I. In a solution containing 0·0093 grm. molybdenum as ammonium molybdate we obtained by electrolysis—

	$Mo_2O_3.3H_2O$.	Mo.
1.	0·0146 grm.	0.0095 grm.
2.	0·0146	0·0095
3.	0·0138	0·0090
4.	0.0137	0·0089
5.	0·0138	0·0090
6.	0·0142	0·0092
7.	0·0143	0·0093
8.	0·0146	0·0095
9.	0·0146	0·0095
10.	0·0146	0·0095

Molybdenum was not found in the filtrate. The time required for the above precipitations was two hours in each case. The current was obtained from four small-size Grove cells.

II. The solution contained 0·0156 grm. of molybdenum. We obtained—

	$Mo_2O_3.3H_2O$.	Mo.
11.	0·0236 grm.	0·0154 grm.
12.	0·0239	0·0156
13.	0·0245	0·0160
14.	0·0228	0·0148

The time of precipitation was two hours. Used four Grove cells. No indications of molybdenum in any of the solutions after the deposition of oxide.

III. A solution containing 0·0167 grm. molybdenum gave—

	$Mo_2O_4.3H_2O$.	Mo.
15.	0·0256 grm.	0·0167 grm.
16.	0·0252	0·0164
17.	0·0258	0·0168
18.	0·0258	0·0168
19.	0·0257	0·0166

Three hours were employed in precipitating the above quantities. Four Grove cells. Molybdenum not found on testing the filtrates.

IV. We found in a solution containing an unknown amonnt of molybdenum—

20.	0·0325 grm.
21.	0·0329
22.	0·0330
23.	0·0315

The time was three hours. Employed the same battery power as in the other determinations; 23 is the only instance where molybdenum was detected.

The action of the current upon molybdenum solutions containing other metals is receiving study at present.—*American Chemical Journal.*

Researches on Uranium.—(Third Treatise).—Clemens Zimmermann.—This memoir and the succeeding one have beeen edited by G. Alibegoff and G. Krüs from the posthumous papers of the late author. Concerning the intermediate oxides of uranium Zimmermann reached the following conclusions:—U_3O_8 is permanent only if heated in a current of oxygen and allowed to cool in it. If U_3O_8 is heated in air and cooled quickly it loses a small and variable quantity of oxygen, which is greatly increased if it is allowed to cool in an indifferent gas. If heated in an indifferent gas, such as nitrogen or carbon dioxide, U_3O_8 is gradually decomposed and completely converted into uranium dioxide. Peligot's black oxide is simply a mixture consisting chiefly of U_3O_8 with more or less UO_2, and has not a definite composition, such as, *e.g.*, U_2O_5. The colour of U_3O_8 is not a decisive mark of its purity, since, when purest, it has often a complete black aspect, whilst the streak, even of black U_3O_8, upon unglazed porcelain is always green. The difference of colour is therefore determined by the density of the preparation and the temperature to which it has been heated. The atomic weight of uranium Zimmermann determines as 239·02.—*Liebig's Annalen*, ccxxxii., Part 3.

Particulars on Commercial Orpiment and on the Unhairing of Hides.—M. Terreil.—This orpiment (*orpen*) is not the true orpiment,—a yellow arsenic trisulphide,—but it is red, and agrees approximately in composition with realgar, or arsenic disulphide. It contains, however, a little trisulphide. It is applied mixed with lime, either to the flesh side of the hide only, if it is intended to preserve the wool or hair, or the hides are entirely immersed in the same mixture. The arsenic sulphide dissolves in the hydrated lime, forming a soluble sulpho-salt which reacts upon the animal tissue, causing it to swell up so that the hairs easily become detached. Hides which have been steeped in water previous to unhairing present afterwards black spots in parts which while still moist have been in contact with articles of rusty iron, or upon which particles of iron have become fixed. There are then formed ferruginous spots, which the sulpho-salt afterwards converts into black iron sulphide. Such spots are most frequent when the skins, before being handed over to the tanner, have been dried in presence of preservative agents, so-called, which contain iron. The black spots consist simply of iron sulphide free from foreign matters.—*Bull. de la Soc. Chim. de Paris.*

HYDRATION OF SALTS.

By Miss E. M. FARRER and S. U. PICKERING.

It is generally assumed that the water of crystallisation contained in a salt is given off at 100°, and as a rider to this assumption we find that whatever water is not evolved till higher temperatures be reached is considered to be not water of crystallisation, but water of constitution, whatever that may mean. This theory finds a ready acceptance in cases where it is possible, however illogically, to represent this water as part of the salt itself, as in the case of the sulphates; but the fact that in many, and perhaps most, other cases, where the formulæ of the salts do not admit of such a view, some water is retained at high temperatures in a precisely similar manner is generally overlooked.

In attempting to prepare specimens of several anhydrous salts this fact has of late been forced on our consideration.

Manganese chloride was one of the salts taken. The crystallised salt, on analysis, was found to contain the theoretical percentage of water corresponding to the formula $MnCl_2,4H_2O$. On being heated in dry air at 100° it lost an amount of water represented as nearly as possible by $3H_2O$ (found 27·05 per cent, calculated 27·30 per cent): a slightly higher temperature, however, sufficed to bring about a further loss, which proceeded at a very slow rate. At 200° to 230° the salt again became constant in weight, having experienced a loss of 37 per cent in one case and 35·9 in another, agreeing moderately well with the theoretical loss for $4H_2O$ of 36·4 per cent. The preparations, however, were found to be by no means anhydrous, even after many hours heating at this high temperature; they still retained about 2·5 per cent of water, the loss in weight which had been experienced having been augmented by the loss of some chlorine in the form of hydrochloric acid, and the consequent formation of some manganous oxide. This oxidation was found to have taken place to an appreciable, though much smaller extent when the salt had been heated to 100° only.

Similar attempts to prepare an undecomposed specimen of the anhydrous salts, by treating the double salt which it forms with ammonium chloride, were unsuccessful. By crystallising solutions of the two chlorides a salt was obtained corresponding to the formula $MnCl_2,4NH_4Cl,3H_2O$, which has not been before described.* It gave on analysis—

	Found.		Calculated.
Cl	54·372		54·159
NH_3	17·635 17·011 17·386	17·344	17·351

This salt, on being heated in dry air, gave off water and ammonium chloride at 100°; but even at 220°, after prolonged heating, it still retained a considerable amount of water, although the ammonium chloride had all been expelled, and about 4 per cent of the salt had been oxidised. The amount of oxide formed in this case was considerably greater than in the previous experiments with the manganese chloride itself, but it no doubt depends on the manner in which the heating is conducted and the rate at which the water is expelled: when samples of the single and the double salt were heated side by side in the air-bath, for two hours at 200°, the former underwent five times as much oxidation as the latter.

The behaviour of the chloride of manganese would appear to be typical of that of the chlorides of most of the dyad metals: with those of iron and magnesium, indeed, the salt is decomposed much more readily than in the case of manganese, and long before it approaches an anhydrous condition: even in a case such as that of strontium chloride, where no appreciable decomposition occurs, 1 per cent or more water is retained at 250°, and cannot be expelled below a red heat. Nor are the chlorides the only salts which retain small quantities of water at temperatures above 200°; the authors have found the same behaviour to be exhibited by sodium pyrophosphate, sodium ferrocyanide, potassium ferrocyanide, and strontium nitrate, and there can be little doubt but that, if the loose and antiquated statements on which our knowledge of the properties of most salts rests were examined with a little care, it would be found that it is only in exceptional cases that a crystallised salt may be completely dehydrated at 100°; at present, at any rate, we may safely conclude that neither 100° nor any other temperature can be taken as that at which water, which must necessarily be considered as water of crystallisation, is given up by a hydrated salt.

The decomposition of the chlorides while being dehydrated is a point of some theoretical interest. It is not due to the oxidising action of the air at the high temperature employed, for both the manganese chloride and the manganese ammonium chloride were found to be oxidised in the same manner when the dehydration was conducted in an atmosphere of hydrogen; nor can it be regarded as due to a limited double decomposition between the salt and the water liberated, for in such cases (that of the magnesium chloride being the most notable and best known one) the salt is stable in the presence of even a large amount of water at 100°, and its solution may be boiled for any length of time without suffering decomposition;* it is only when the component parts of the compound molecule are being split asunder,—

$$[(M''Cl_2)(\alpha H_2O)]$$

that this decomposition occurs. Two explanations of this fact may be offered: first, that such compound molecules are not in reality so simple in construction as they are represented; that the water present, though still water of crystallisation, is united to the chloride, not as molecule to molecule, but through the valencies of the compound atoms in these molecules, so that the water cannot be removed without affecting the atoms composing both itself and also the $M''Cl_2$,—a view which one of us has elsewhere given in detail: or, secondly, that the molecule of the hydrated salt, not being in reality $M''Cl_2\alpha H_2O$, but $x(M''Cl_2\alpha H_2O)$, when decomposed so as ultimately to form molecules which may be represented as $y(M''Cl_2)$ and $z(H_2O)$, gives rise to the transitory existence of the isolated—or, as we may perhaps call them, nascent—molecules, $M''Cl_2$ and H_2O, which, being very different from the complex arrangement which actually constitute the units of any substance in a stable condition, react with each other in a manner in which the more stable molecular aggregates are incapable of doing.

* The manganese ammonium chlorides already known are—
$MnCl_2,2NH_4Cl$, H_2O (Rammelsberg, Pickering);
$MnCl_2,2NH_4Cl,2H_2O$ (v. Hauer);
$MnCl_2$, $NH_4Cl,2H_2O$ (Hautz).

* The anhydrous chlorides, in those cases where they have been obtained by indirect means, have also been found to be perfectly stable at these temperatures.

ON THE

WIDESPREAD OCCURRENCE OF ALLANITE AS AN ACCESSORY CONSTITUENT OF MANY ROCKS.

By JOSEPH P. IDDINGS and WHITMAN CROSS,
Of the U.S. Geological Survey.

More than a year ago, while engaged in the microscopical study of rocks from widely separated regions, the writers observed in the thin sections occasional crystals or grains of a highly refracting brown mineral, which was not referable to any of the more common rock-building species. The study of a number of sections showed that the crystals were monoclinic and apparently isomorphous

with epidote, that is, elongated in the direction of the ortho-axis with the base and orthopinacoid well developed, two positive orthodomes less prominently, and with terminal planes belonging apparently to the unit prism. In a few instances imperfect cleavage was noticed parallel to *i-i* and *O*, and in one case to *i-ī*. A twining parallel to *i-i*, as in epidote, was frequently observed.

The optical axes were found to lie in the plane of symmetry, one of the bisectrices making an angle of 35° to 40° with the vertical axis and 25° to 30° with the clino-axis. A strong pleochroism, from light yellowish brown to dark chestnut brown, was always noted, as also a high index of refraction. These characters strongly indicated the identity of this mineral with allanite, and a qualitative chemical analysis, made by Dr. W. F. Hillebrand in the Denver laboratory of the U.S. Geological Survey, fully confirmed the correctness of the microscopical determination. The material analysed was derived from a biotite porphyrite of the Ten Mile District, Colorado, in which the mineral occurred in exceptional abundance. The process of separation and analysis is described by Dr. Hillebrand as follows: "The mineral supposed to be allanite was separated from the rock, together with much magnetite and some zircon, by means of the Sonstadt solution. The magnetite being removed by a magnet, the other minerals were left quite free from further admixture. They formed approximately 0·05 per cent. of the whole rock.

"In order to preserve the zircon crystals intact, the mixture was treated, without pulverisation, for many days in a platinum crucible with hydrochloric acid. The residue was zircon and silica retaining the original form of the allanite fragments. This silica after filtration was entirely soluble in hot sodium carbonate. After separating silica in the hydrochloric acid solution, the latter was boiled with potassium hydrate. The filtrate then showed much alumina and lime, and very little magnesia. The precipitate by potassium hydrate was dissolved in hydrochloric acid, diluted, and to it a concentrated solution of oxalic acid added. The precipitate, at first curdy, was ignited, dissolved in sulphuric acid, evaporated, and ignited gently, the sulphates dissolved in cold water, and crystals of potassium sulphate added. After washing the insoluble double sulphate formed with a potassium sulphate solution, ammonia formed no precipitate in the filtrate, showing the absence of erbium and yttrium. The double sulphates dissolved very readily in water acidulated with hydrochloric acid, and were then decomposed by oxalic acid; the ignited precipitate was brown, readily soluble in hydrochloric acid with evolution of chlorine, indicating thereby the presence of both cerium and lanthanum, and absence of thorium. No didymium absorption lines were visible in the spectroscope. The oxalates, when dissolved in strong nitric acid and boiled with lead dioxide, gave a yellow solution showing the presence of cerium. Further tests were rendered impossible by the loss of the material.

"Although in the beginning only a qualitative analysis was contemplated, owing to the small amount of material, nevertheless the silica, alumina, ferric oxide, mixed cerium and lanthanum oxides, and the lime were weighed, and found to bear to one another the average ratio of those constituents in allanite."

Considering the identity of the mineral as established, the following additional particulars as to its characteristics and distribution may be of interest.

Crystals which are large enough to be seen without the aid of a lens are easily recognised in the hand specimen by their brilliant black colour, uneven fracture, and oily lustre. They vary greatly in form and size in the different rocks examined, in some cases being long slender prisms, reaching a maximum length of 1 c.m., though usually appearing in short, stout prisms, or in quite irregular grains of microscopic dimensions. In thin sections from a great number of localities the colour is uniformly a rich chestnut-brown with the strong pleochroism already mentioned, but in a few instances a zonal variation has been noticed, the colour growing lighter from the centre of the crystal outward. Cleavage is in most cases wholly absent.

A confusion with hornblende or biotite is only possible when these minerals are of nearly the same shade of brown, and are so cut by the section as to show no distinct cleavage. But the lack of pleochroism and the nearly uniaxial character of a basal section of biotite—the only one not exhibiting cleavage—sufficiently distinguishes it from the strongly pleochroic, biaxial allanite. In the exceedingly rare cases where hornblende possesses the peculiar chestnut-brown color, and shows neither characteristic cleavage nor outline, one can only distinguish the allanite by its higher index of refraction, which produces more brilliant interference colours between crossed nicols.

From its mode of occurrence and association allanite must be added to the group of primary, accessory rock constituents, similar to zircon, sphene, and apatite, though much rarer than any of these. In one instance it was noticed enclosing zircon, in others, sphene, apatite, and magnetite, but it has also been found in such connection with these minerals as to indicate a contemporaneous growth. Its nature as a primary constituent in eruptive rocks is further attested by its occasional inclusion in biotite, felspar, and quartz.

In some regions it appears to be quite uniformly distributed through certain types of rock. Thus, in the porphyrites and allied porphyries of the Ten Mile district, Colorado, prismatic crystals of allanite may be seen in numbers upon nearly every hand specimen—one exhibiting as many as forty on its surface—and few thin sections of these rocks were examined without one or more being discovered. On the other hand, in the vicinity of Eureka, Nevada, it seems to be very irregularly disseminated through a considerable range of rock types, two or three microscopical individuals being recognised in quite a number of thin sections—and in one instance as many as eleven—but in the majority of sections it is absent altogether. In most of the rocks studied the mineral occurs very sparingly.

In almost every instance the allanite is perfectly fresh and unaltered. Macroscopic crystals are occasionally seen to be reddish brown in colour, with a more or less deeply stained zone surrounding them. In one partially decomposed rock, a transition of allanite to epidote is indidicated by crystals of the former enclosing scattered grains of epidote in such a manner as to leave little doubt that they result from an alteration of the enclosing mineral.

It is interesting finally to notice how extensively allanite is disseminated in minute quantities through rocks of a great variety of types and from widely separated localities. Without undertaking any special investigation of the matter we have found it microscopically in metamorphic rocks, in older crystalline eruptive masses, and in glassy lavas; in hornblende gneiss and mica gneiss, in granite, granite porphyry, quartz porphyry, diorite, porphyrite, andesite (glassy), dacite, and rhyolite; and from localities in the States of Maine, Massachusetts, Rhode Island, Colorado, and Nevada, and the Territories of Wyoming and Utah. Below is appended a list of the rocks and localities alluded to, which will no doubt be greatly enlarged by other observers.

Gneiss.—Utah: Ogden Cañon; Farmington Cañon, Wahsatch.
Wyoming: Medicine Bow Range.
Nevada: Clover Cañon, E. Humboldt Mountains.

Granite.—Maine: Vinalhaven, Biddeford, Wayne, Fox Island, Harrington.
Massachusetts: Lynnfield.
Rhode Island: Westerly.
Utah: Little Cottonwood Cañon.
Nevada: Eureka.

Granite Porphyry.—Utah: Tooele.
Nevada: Eureka.
Quartz Porphyry.—Colorado: Mosquito Range, Park County; Eagle River, Eagle County.
Diorite.—Nevada: Truckee Cañon.
Porphyrite.—Colorado: Mount Silverheels, Park County; Mosquito gulch, Park County; Ten Mile District, Summit County.
Utah: Henry Mountains.
Andesite (glassy).—Nevada: Eureka.
Dacite.—Nevada: Eureka, Shoshone Park; Washoe.
Utah: White Rock Mountain.
Rhyolite.—Nevada: Eureka.

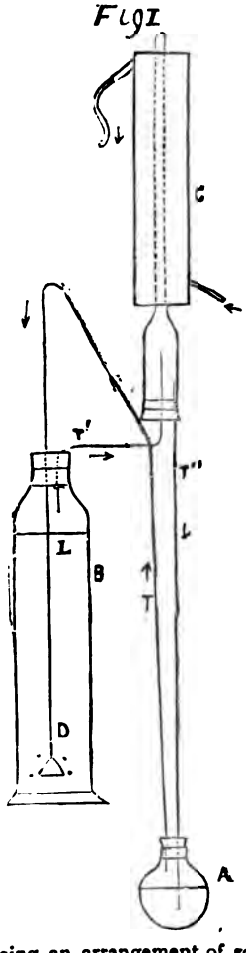
APPARATUS FOR THE EXTRACTION OF DISSOLVED SUBSTANCES FROM LIQUIDS WITH LIGHT VOLATILE SOLVENTS.

By ARNOLD EILOART, B.Sc.

APPARATUS for this purpose have been recently described by Neumann (*Ber. d. Deutsch. Gesell.*, xviii., 3061). In this case a syphon was used to remove the solvent after it had passed through the liquid to be extracted, and I had

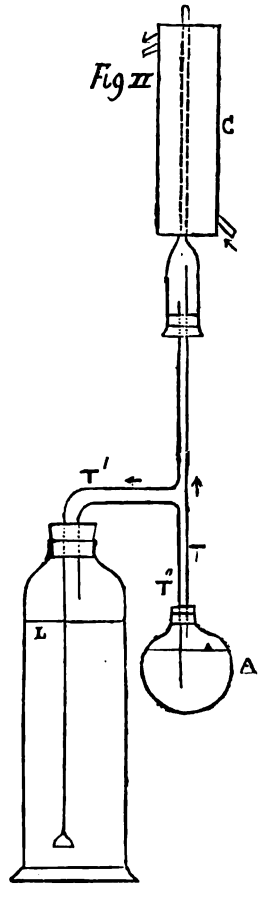
Fig I



myself been using an arrangement of somewhat similar principle. But in the course of work the following simple method was found preferable.

The solvent in the flask A (fig. 1) is heated by means of a water-bath, so that the vapour passes through the tube T to the bottom of the liquid to be treated with it (L), which is placed in the vessel B. As B is tightly corked, the condensed solvent, collecting above L, is next forced up the tube T' (which opens above the surface of L) and into the open condenser, C, from the bottom of which it is carried off by the tube T'' to return to A. The extra height of T above B checks regurgitation when A cools. It is evident that external heat may be applied to B to aid the extraction. If, on the other hand, it is necessary to avoid heating L by the condensation of the solvent, the arrangement shown in fig. 2 is adopted. Here the vapour passes first to the

Fig II



condenser, C, by the tube T, and the condensed solvent collects in T', which is of such a height that, by the weight of the column of liquid in that tube, a stream is forced through L and up T'', thus effecting the return to A. Some arrangement for spreading the solvent on its entrance to L will be found useful. For this a funnel (D) was fused to the tube T (fig. 1), and over its mouth platinum pierced with pin-holes was folded.

King's College Laboratory,
June, 1886.

Spontaneous Polymerisation of Volatile Hydrocarbons at Ordinary Temperatures.—Sir H. E. Roscoe, F.R.S.—The most volatile fractions of the hydrocarbons obtained on distilling crude phenol at a red heat are converted spontaneously into a crystalline hydrocarbon of the formula $C_{10}H_{12}$.—*Liebig's Annalen.*

ON ALLANITE AND GADOLINITE.*

By L. G. EAKINS.

The three minerals about to be described were analysed during the spring of 1885, and are part of a number collected by Mr. W. B. Smith, of the U.S. Geological Survey, and turned over by him to the laboratory of the survey for investigation, the remaining ones now being in the hands of Mr. W. F. Hillebrand. They are all from the same locality, namely "Devil's Head" Mountain, Douglas County, Col., the region being already described by Mr. Smith in the *Bulletin of the U.S. Geological Survey*, No. 20.

For the microscopical notes in connection with the following descriptions, I am indebted to Mr. Whitman Cross.

Allanite.

Allanite occurs scattered throughout a more or less decomposed granite, from which it was separated for analysis by the Thoulet solution.

Colour:—Pitch-black.

Lustre:—Brilliant, glossy.

Fracture:—Sub-conchoidal.

Microscopical:—Interior pale greenish yellow, with irregular fissures. Isotropic, often there is a zone about the kernel, which is chestnut to strong yellowish brown, pleochroic, and strongly doubly refractive.

This outer zone is identical in behaviour with the allanite of eruptive rocks. From the presence of apparent rude prismatic forms one would infer that the amorphous state is in this case a secondary one.

Heated before the blowpipe a fragment swells to several times its original size. It is readily decomposed by acids.

Sp. gr. 3·52 at 29° C.

H. about 6.

The analysis is as follows:—

SiO_2	31·13
Al_2O_3	11·44
Fe_2O_3	6·24
Ce_2O_3	12·50
$(LaDi)_2O_3$	10·98
FeO	13·59
BeO	0·27
MnO	0·61
CaO	9·44
MgO	0·16
K_2O	trace
Na_2O	0·56
H_2O	2·78
CO_2	0·21
P_2O_5	trace
	99·91

Gadolinite.

Of this mineral there were two specimens, of which separate analyses were made; they are figured in the Table below as I. and II.

The description of the material which furnished Analysis I. is as follows:—

The specimen resembled, externally, a stone worn and rounded by the action of water: when broken, a black, slightly lustrous surface was exposed.

Fracture:—Smooth.

Cleavage:—Apparently none.

Microscopical:—Dark green. Isotropic.

The section was fissured, with films and flakes of dark reddish brown oxides in them.

Before the blowpipe it glows brilliantly.

Sp. gr. 4·56 at 17° C.

H. 6—6 5.

The material which furnished Analysis II. differs very much in appearance from the one just described.

* *Proceedings of Colorado Scientific Society*, vol. ii., 1885.

It also was in fragments, but none of them displayed the worn, rounded appearance of the other.

In colour it was less dark, approaching at places to a dull green.

Sp. gr. 4·59 at 25·5° C.

H. about 6.

As these two analyses are the first of material from this country it has been considered advisable to add the analyses of gadolinite from two of the noted European localities. They are given in the Table as III. and IV., III. being from Ytterby and IV. from Hitteroe. They are taken from an article by Humpidge and Burney in the *Zeitschrift fur Krystallographie*, vi., p. 94.

	Eakins.		Humpidge and Burney.	
	I.	II.	III.	IV.
SiO_2	22·13 (*b*)	21·86	25·16	24·24
Al_2O_3	2·34	0·54	—	—
Fe_2O_3	1·13	3·59	2·15	—
ThO_2	0·89 (*c*)	0·81	—	—
Ce_2O_3	11·10 (*c*)	6·87	Ce, La, Di O_3 6·52	9·93
$(LaDi)_2O_3$ ..	21·23	19·10 (*e*)		
Er_2O_3	12·74 (*d*)	15·80 (*f*)	4·11	10·91
Y_2O_3	9·50 (*d*)	12·63 (*f*)	35·16	30·59
FeO	10·43	11·36	12·40	16·04
BeO (*a*)	7·19	5·46	9·39	6·56
MnO	—	0·11	—	—
CaO	0·34	0·47	1·11	0·79
MgO	0·14	0·16	trace	0·24
K_2O	0·18	0·20	—	trace
Na_2O	0·28	0·32	—	—
H_2O	0·86	0·74	2·32	0·62
P_2O_5	—	—	1·28	—
Total ..	100·48	100·02	99·60	99·92

(*a*) Humpidge and Burney use Be_2O_3 instead of BeO.

(*b*) Mean of 22·10 and 22·15.

(*c*) A second determination gave for $ThO_2 + Ce_2O_3$ = 11·82.

(*d*) The molecular weight of the mixed oxides Er_2O_3 and Y_2O_3 = 296.

(*e*) Didymium absorption line very strong.

(*f*) The molecular weight of the mixed oxides Er_2O_3 and Y_2O_3 = 294.

In Analysis I. and II. the Er_2O_3 and Y_2O_3 were calculated by the formula of Bahr and Bunsen, after the conversion of the oxides into sulphates.

Er_2O_3 = 4·79 wt. oxides — 2·33 wt. sulphates.

The absorption spectrum of erbium from one grm. of the mineral in a solution 2 c.m. thick and 1 c.m. deep was so weak that only the band in the green was visible, being but little darker than the two dark Fraunhofer lines on each side.

In the notes in connection with the analyses given here as III. and IV., Humpidge and Burney make the following remarks:—

"The P_2O_5 (for the first time discovered in gadolinite), is combined with cerium metals, for it remains undissolved on treatment with aqua regia. Xenotime could not be detected in thin sections, the whole appearing as a homogeneous, isotropic, green mass. The above analyses contradict the statement of Descloiseaux that the amorphous gadolinites are free from Be_3O_3."

It will be noticed in regard to this last statement that my analyses lead to the same conclusion.

On Lanoline.—M. Boymund.—Lanoline, a fat derived from the suint of wool, is a perfectly neutral body, and does not lose its neutrality under the influence of water. It is easily miscible with fatty bodies, and dissolves in ether, chloroform, benzol, and carbon disulphide, but it is insoluble in alcohol even with the aid of heat. The author has studied its properties from a pharmaceutical point of view.—*Journ. de Pharm.*

PROCEEDINGS OF SOCIETIES.

CHEMICAL SOCIETY.

Thursday, June 3rd, 1886.

Dr. HUGO MÜLLER, F.R.S., President, in the Chair.

CERTIFICATES were read for the first time in favour of Messrs. Bennett F. Davenport, M.A., M.D., 751, Tremont Street, Boston, Mass.; W. Ralph Dodd, 55, Listria Park, Stoke Newington; Albert Brown Lyons, M.A., M.D., Detroit, Michigan, U.S.A.; James B. Readman, F.R.S.E., 9, Moray Place, Edinburgh; Edgar F. Smith, Ph.D., Wittenberg College, Springfield, Ohio.

The following papers were read:—

55. "*Notes on Sir W. Fairbairn's Experiments on Re-melting Cast Iron.*" By THOMAS TURNER, Assoc. R.S.M.

In 1853 Sir W. Fairbairn re-melted Eglinton hot-blast pig iron 18 times in order to ascertain the effect produced by repeated melting (*B. A. Report*, 1853, 87). The metal at first gradually improved, but afterwards rapidly deteriorated, becoming white and hard. The following analyses of the bars are due to Crace Calvert.—

1st melting	..	Si = 0·77		S = 0·42		C = 2·76
8th	„	..	„	1·75	„	0·60	„ 2·30
10th	„	..	„	1·98	„	0·26	„ 3·50
18th	„	..	„	2·22	„	0·75	„ 3·75

The author recently attempted, with the aid of these results, to explain the effect observed. The accuracy of these analyses had been questioned by Snelus and others, and by the kindness of Professor Unwin the author has been enabled to repeat the chemical examination. His results have been confirmed by separate analyses performed by Mr. J. P. Walton. The mean of their experiments give the following results:—

No. of melting.	Total carbon.	Combined.	Silicon.	Sulphur.	Manganese.	Phosphorus.
1	2·67	0·25	4·22	0·03	1·75	0·47
8	2·97	0·08	3·21	0·05	0·58	0·53
12	2·94	0·85	2·52	0·11	0·33	0·55
14	2·98	1·31	2·18	0·13	0·23	0·56
15	2·87	1·75	1·95	0·16	0·17	0·58
16	2·88	—	1·88	0·20	0·12	0·61

It follows, therefore, that the author's previous conclusions, based upon Calvert's analyses, were erroneous, and that the action of re-melting was one of oxidation, resembling in character that of the "refinery," the puddling furnace, the open-hearth furnace, or the Bessemer converter.

56. "*Some Ammonium Compounds and other Derivatives of α-1′ Hydroxyquinoline.*" By C. A. KOHN, B.Sc., Ph.D.

The author first describes the methiodide of hydroxyhydromethylquinoline and its conversion on being heated with solid caustic potash into methoxyhydromethylquinoline: he regards this isomeric change as being due to the formation, in the first place, of potassoxyhydromethylquinoline methiodide, from which potassium iodide is then split off, the added methyl group taking the place of the displaced potassium. Methoxyhydromethylquinoline methiodide is converted by moist oxide of silver into the corresponding hydroxide, which on heating is decomposed into methyl alcohol and methoxyhydromethylquinoline. The corresponding hydroxyhydroethylquinoline compounds are described. Hydroxyhydroethylquinoline ethiodide yields with caustic potash O. Fischer's ethylkairin; the corresponding hydroxide appears to be decomposed on heating into ethylkairin, ethylene, and water. An attempt to prepare a benzyl chloride addition-product of hydroxyhydromethylquinoline was not attended with a satisfactory result: on heating the product with caustic potash what appeared to be a benzylhydromethylquinoline was, however, obtained, and hence it is most probably the added radicle that is displaced.

Acetoxyhydroethylquinoline was also prepared. It possesses only feeble basic properties, and is readily decomposed. By the action of ethylene bromide on hydroxyhydroquinoline a hydroxyhydroethylenequinoline was obtained. Several salts and characteristic reactions of this derivative are described: it is a weak base as well as a weak acid. An investigation of its physiological properties by Professor Filehne shows that it acts like kairin in reducing temperature, but that its action is a far feebler one—a fact due in all probability to its weaker basic properties. The effect of nitrating ethoxyhydroethylquinoline is also mentioned: two nitro-groups are at once introduced, as is the case with hydroxyquinoline.

57. "*β-Sulphophthalic Acid.*" By Prof. C. GRAEBE and A. RÉE, Ph.D.

The preparation and properties of this acid, in which COOH : COOH : SO_3H = 1 : 2 : 4, and of its salts, are fully described: it may be obtained either by oxidising commercial naphthol yellow S.—dipotassium dinitro-alphanaphtholsulphonate—with nitric acid, or by the action of sulphur trioxide on phthalic anhydride, a relatively small amount of the isomeric 1 : 2 : 3 sulphuric acid being also formed in the latter case. The purification of the acid is best effected by means of the monobarium salt, $[C_6H_3(CO_2H)_2.SO_3]_2Ba.5OH_2$, one of the most characteristic of its salts. On evaporating an aqueous solution in the water-bath to a syrup, and completing the removal of water by heating in the air-bath below 100°, β-sulphophthalic acid is obtained as a crystalline monohydrate; on heating this at 140° the acid is obtained as a thick syrup, which may be converted by prolonged heating at 180° into a crystalline mass of anhydrosulphonic acid, $C_6H_3(C_2O_3).SO_3H$. On treatment with PCl_5, sulphophthalic acid yields two acid chlorides—a crystalline monochloride, $C_6H_3(COOH)_2.SO_2Cl$, from which the corresponding sulphonamide may be obtained by the action of ammonia, and a non-crystalline trichloride, $C_6H_3(C_2O_2Cl_2).SO_2Cl$, which decomposes on distillation into SO_2 and β-chlorophthalic chloride.

58. "*Compounds obtained by the aid of β-Sulphophthalic Acid.*" By the same.

β-Hydroxyphthalic acid was obtained by fusing sodium β-sulphophthalate with 2½ times its weight of sodium hydroxide at a temperature not exceeding 180°; if this temperature be much exceeded, methydroxybenzoic acid is produced, this acid being also formed in theoretical quantity on heating β-hydroxyphthalic acid with dilute muriatic acid at 180°.

β-Hydroxyphthalimide was prepared by acting with ammonia on β-hydroxyphthalic anhydride; it is converted into *β-hydroxyphthalide* by digestion with tin and muriatic acid, and treatment of the nitroso-derivative of the β-hydroxyphthalidine thus formed with caustic soda.

By heating the monochloride of β-sulphophthalic acid with phosphorus pentachloride at 220°, a quantitative yield of *β chlorophthalic chloride*, and consequently of β-chlorophthalic acid, may be obtained. The chloride boils at 275°; *β-chlorophthalic anhydride* melts at 99° and boils at 296° (corr.). The same methylic salt is obtained by the action of methylic alcohol on β-chlorophthalic chloride and anhydride, and by the action of methyl iodide on silver β-chlorophthalate: this result is of interest, as on the assumption that phthalic chloride is of unsymmetrical constitution ethereal salts prepared from a phthalic chloride should differ from those obtained either from the anhydride or the silver salt, and this has been proved to be true in the case of tetrachlorophthalic acid.

β-Chlorophthalimide, obtained by the action of ammonia on the anhydride, melts at 210—211°. *β-Chlorofluorescein* closely resembles fluoresceïn.

By the action of aluminium chloride on a benzene solution of β-chlorophthalic anhydride, *metachlorobensoyl-*

benzoic acid is formed, from which *metachloranthraquinone* is readily obtained by condensation with sulphonic acid.

On fusion with sodic formate, β-sulphophthalic acid yields trimellitic (1 : 2 : 4 benzenetricarboxylic) acid.

59. "*Derivatives of Taurine.*" Part II. By J. William James.

An account is given of experiments to determine the constitution of the trimethyltaurine previously described by the author (*Trans.*, 1885, 367). Boiling iodhydric acid has no action on it: therefore, as all compounds containing methoxyl yield methyliodide when thus heated, the formula $NMe_2 \cdot C_2H_4 \cdot SO_2OMe$ is excluded. Trimethyltaurine is readily decomposed by boiling with alkalies, trimethylamine and isethionate being formed; cyanamide does not combine with it: hence it must be supposed that it differs in constitution both from taurine and the mono- and dialkyl-taurines—which are not decomposed by alkalies, but all form crystalline compounds with cyanamide. The author therefore represents the trialkyltaurines alone as analogues of betaine, thus:—

$C_2H_4\begin{cases}NH_2\\SO_2\cdot OH\end{cases}$ Taurine. $C_2H_4\begin{cases}NHR'\\SO_2\cdot OH\end{cases}$ Monalkyltaurine. $C_2H_4\begin{cases}NR_2'\\SO_2\cdot OH\end{cases}$ Dialkyltaurine.

$C_2H_4\begin{cases}NR_3'\\ \diagdown\\SO_2\cdot O\end{cases}$ Trialkyltaurine.

Finally, a description is given of an *imide* of the formula

$$C_2H_4\begin{cases}NH\\SO_2\end{cases},$$

obtained by the action of dry ammonia-gas on an ethereal solution of β-chlorethanesulphonic chloride,—

$$Cl\cdot C_2H_4\cdot SO_2Cl;$$

it is an extremely stable body, not being decomposed by boiling with alkalies; the imidic hydrogen can be displaced by metals.

Discussion.

Dr. Armstrong expressed the opinion that the properties of taurine and its derivatives were such that it was impossible to represent them as sulphonic *acids*; he thought that they were all equally to be regarded as ammonium compounds of the glycine and betaine type, and, judging from their physical properties, that neutralisation was probably brought about by the union of 2 mols. of the parent amido-sulphonic acid. The evidence brought forward was scarcely sufficient to warrant the assumption that trimethyltaurine was esentially different in constitution from taurine and the mono- and di-alkyl-taurines.

Dr. Sprengel desires it to be mentioned that at the meeting on May 20th he also exhibited three photographs taken at the moment of the explosion at Hell Gate, October 10th, 1885, when the mine was charged with 22 tons dynamite and 107 tons of a mixture of 21 parts nitrobenzene and 79 parts potassium chlorate. This mixture belongs to the safety explosives described by Dr. Sprengel in the *Chem. Soc. Journ.*, 1873, and according to General Abbot, U.S. Army, has the power 109, dynamite with 75 per cent nitroglycerine being 100.

At the next meeting, on June 17th, there will be a ballot for the election of Fellows, and the following papers will be read:—

1. "The Electrolysis of Aqueous Solutions of Sulphuric Acid." By Prof. H. McLeod, F.R.S.
2. "Essential Oils (Part III.), their Refractive and Dispersive Power." By Dr. J. H. Gladstone, F.R.S.
3. "The Formation and Destruction of Nitrates and Nitrites in Artificial Solutions and in River and Well Waters." By J. M. H. Munro, D.Sc.
4. "An Apparatus for Distillation under Reduced Pressure." By Dr. W. H. Perkin, F.R.S.
5. "The Electromotive Force produced by the Combination of Cadmium and Iodine in Presence of Water." By A. P. Laurie.
6. "A Method of Investigating the Constitution of Azo-, Diazo-, and Analogous Compounds." By R. Meldola, F.R.S., and F. W. Streatfeild.

TOKYO CHEMICAL SOCIETY.

The eighth annual meeting of this Society was held on April 10th, at the Botanical Garden of the Imperial University, Tokyo, Japan.

About thirty-five members of the Society met together, and amongst the guests present there were Drs. Divers, F.R.S., Wagener, Kellner, and Fesca; Mr. Watanabe, the President of the Imperial University; Mr. Orita, the head of the Educational Bureau; Professors Kichuchi, Yatabe, Ozawa, Shida, and Yamakawa.

The chair was taken at 4 p.m. by Prof. J. Sakurai, the President of the Society, who reported on the condition of the Society for the year ending March, 1886. The following is a brief abstract of the Report:—

"The increase in the number of members during the year is 12, and the total number of members at present is 86, of whom 59 are in Tokyo, 21 in provinces, and 6 abroad.

"Ten ordinary meetings and one annual meeting were held during the year, at the latter of which Dr. Divers delivered an important lecture on the 'Constitution of some Non-saturated Oxygenous Salts,' a paper which cost him a long and laborious experimental work, and which, in spite of the serious accident he had then only lately had, he read with unusual force and clearness.

"The number of papers contributed and read by the members at ordinary meetings amounts to 19, which are either of theoretical interest or of practical importance. Especially important, however, of these are the papers contributed by Mr. T. Shimizu,—the joint work of Dr. Divers and himself,—and a paper on the 'Chemical Examination of the Constituents of Camphor Oil,' by Mr. H. Yoshida.

"The *Journal* of the Society is published four times a year, viz., in March, June, September, and December, and it is hoped to make it in future a monthly journal, especially as the number of papers annually read is not very few, nor their nature inferior to those which appear in foreign journals.

"The Society has undertaken to translate chemical terms into Japanese, and it now possesses a Dictionary of commoner chemical terms in Japanese, English, French, and German.

"It has also undertaken to establish a system of chemical nomenclature in Japanese language, of which the nomenclature of elements and of inorganic compounds is already nearly finished. It is hoped that a sound and complete system of nomenclature will be published during the ensuing year.

"The donations to the Society are of various kinds and from various sources. They consist of journals of scientific societies, including Russian Chemical Society, 80 copies; pamphlets, 11 copies; books, 3 copies; reports and tables, 8 copies."

Mr. Watanabe, the President of the Imperial University, and Dr. O. Kellner having promised to address the Society, the Chairman then called upon the former gentleman to deliver his discourse.

The object of Mr. Watanabe's speech was to impress upon the minds of the members the necessity of making chemistry popular. He said that chemistry and physics, among other branches of Science, are the two which are most intimately connected with arts and manufactures, and that it is therefore highly necessary for chemists to show to the public that much improvement in our modern industry may be made by proper application of chemical

and physical sciences, and thus much time, labour, and money saved. Any science, he would say, which did not contribute to the improvement of the material world would, in the end, perish; and any scientific society which, however high its aim may be, did not encourage the applied aspect of the science would also, in the end, perish. He would therefore venture to suggest that the members of this Society should try their utmost to show to men of business that material benefits may accrue from their science. He, however, by no means imagines that original investigation is useless; on the contrary, he would strongly encourage it, and hopes that more original work may be done in our country.

Dr. KELLNER's paper was entitled "*On the Application of Human Excreta as Manure: the Deportment of Urea toward Soils.*" This is the result of an experimental investigation carried out at Komaba Agricultural College by Dr. Kellner, Professor of Agricultural Chemistry, with assistance of his pupils; and the following is its brief abstract:—

"It is a general custom, both in Japan and China, to use human excreta as manure, only in a *highly decomposed state.* The application of fresh excreta is regarded as objectionable, it being said that the plants supplied with them are liable to wilt.

"Having been consulted about this injurious influence, and nothing being known in regard to it, I resorted to a few experimental researches in order to find out its cause.

"Fresh excreta differ from decomposed ones in a two-fold way: on the one hand, the reaction of the former is acid, that of the latter alkaline; and on the other, but connected with the difference of reaction, the fresh urine is rich in urea, while the decomposed one is almost destitute of it, *the urea being converted during putrefaction into ammonium carbonate.*

"All considerations lead to the conclusion that the difference of reaction cannot explain the injuries done by fresh excreta, the acid as well as the alkaline reactions being soon neutralised by common soils. But the urea of fresh urine might in some way interfere with the normal process of vegetable growth.

"Owing to the weak affinities of urea, it was hardly to be expected to enter into chemical combination with the ingredients of soils, while ammonia is usually rapidly absorbed by them, so that the fluids left behind are almost free from it. Our researches have indeed corroborated this opinion: *urea is not absorbed by soils, but totally left in solution.*

"Human urine contains about 2 per cent of urea, and even when diluted with an equal bulk of water (as farmers do) it still represents so strong a solution that plants cannot live in it. The agricultural plants grow best in nutritive solutions containing ¼ to ½ part of nutrients per 1000 parts of water, while the diluted urine as applied in Japan contains still 10 parts of urea per 1000 parts of water, besides a fair proportion of common salt and sulphates, which are, as we know, likewise not absorbed by soils.

"The injurious effect exerted by too strong nutritive solutions consists, as is commonly known, in preventing or hindering the diffusion of water from the soil into the roots: hence the plants wilt.

"The conversion of urea into ammonium carbonate is accomplished, within a few days, as well when the excreta are kept in air as when put into soils. As this process is, however, performed by lower organisms (bacteria and micrococci), and as the latter can live but near the surface of soils where oxygen is present, it was expected that in a certain depth of the ground urea may not be altered.

"Researches, made with every possible precaution to prevent the access of atmospheric germs into the solutions and bottles, have indeed shown that, even in the porous soil of Komaba (volcanic ash), *ammonification can be performed only to a depth of 60 centimetres.*

"Urea solutions kept in contact with samples of soil taken from depths of 60 to 65, 120 to 125, 150 to 155 c.m. did not contain any trace of ammonia after a lapse of two months, while surface soils (0 to 5 c.m.) speedily converted the whole of urea employed, so that after sixteen days no more urea could be found. The next layer, taken from a depth of 25 to 30 c.m., accomplished the conversion far more slowly, so that this process was not yet completed after two months.

"Farmers, using fresh urine, run consequently the risk not only of injuring their crops, but also of losing a great deal of the most valuable nitrogenous compound of this manure by rain, which carries the urea into deep sub-soils beyond the reach of the roots of plants.

"The results of these researches are valid not only with regard to human excreta, but also, to a certain extent, with reference to the urine of the live stock."

The CHAIRMAN, in proposing a vote of thanks to the lecturers, referred to the very great interest and much practical importance which attaches to Dr. Kellner's experimental work.

The formal part of the meeting having been terminated, the guests and the members then adjourned to the dining room, which, owing to the hospitality of the officers of the Botanical Garden, was largely and elegantly supplied with rare and beautiful botanical specimens.

One interesting and important feature of the day was the exhibition of new and interesting chemical compounds obtained by the members during the year, and of new pamphlets, books, apparatus, and other objects of chemical interest. This chemical exhibition, inaugurated on the occasion of the sixth annual meeting in 1884, has always proved to be of great success, as on the present occasion, and has, moreover, served as a good means of encouraging original work among the members.

NOTICES OF BOOKS.

Chemistry for the Gold Fields: Including Lectures on the Non-metallic Elements, Metallurgy, and the Testing and Assaying of Metals, Metallic Ores, and other Minerals, by the Test-tube, the Blowpipe, and the Crucible. By JAMES G. BLACK, D.Sc., Professor of Chemistry, Metallurgy, and Assaying in the University of Otago and the Otago School of Mines. Dunedin: Horsburgh.

THE peculiar character of this book, as we learn from the preface, is that "while dealing lightly and very generally with the non-metallic elements and with those departments of chemistry which have no immediate bearing on the pursuits of the miner, it treats pretty fully such subjects as have a direct reference to the mineral resources of the country." In other words, we have here a treatise on chemistry for miners, and more especially for gold miners.

It need scarcely surprise us, therefore, to find certain elements omitted. But we might expect to find a notice of tellurium, which frequently accompanies gold, and of vanadium, which possesses certain most valuable properties and is found to be much more widely diffused than it was recently supposed. The account of platinum is somewhat meagre, and its accompanying metals, palladium, rhodium, iridium, osmium, &c., are dismissed with the remark that "the remaining metals of the gold family are not of sufficient importance to require notice in this treatise." To this opinion we must venture to demur; iridium, palladium, and rhodium are decidedly useful, and if their characteristics were made known to miners and prospecters it is very possible that they might be found in larger quantities.

The author's classification of the elements is peculiar: boron and silicon, for instance, being placed among the halogens. This, however, is a matter of small importance.

Some of the atomic weights of the elements as here given are not in accordance with the most recent determinations. Thus, *e.g.* gold and platinum are both given as 196·7. In the probable case of a second edition these figures will doubtless undergo revision.

Under "carbon" we find a prolonged and eulogistic account of coal-gas, containing a number of most questionable statements. Thus, we read that gas "blazes away on its luminous path in increased 'sweetness and light,' defying for cheapness, safety, and efficiency every competitor." Now the "sweetness" of gas is, to us at least, a something unknown. Even if absolutely freed from every trace of sulphur, which is in practice impossible, its own specific odour is disgusting. As for "safety," those who have witnessed, *e.g.*, the explosion which tore up streets and wrecked houses from Charlotte Street, Fitzroy Square, to a point some distance to the east of Tottenham Court Road will form their own opinion.

But the author, warming to his subject, goes still further. He writes:—"Messrs. Murdoch and Winsor (more correctly Winzer) succeeded at last in convincing the Londoners either that the gas no longer produced the acids, stinks, and smoke complained of, or, if it did, so much the better; for these are beneficial, on the one hand, to the moral welfare of the consumers as giving occasion for exercising the virtues of patience, forbearance, and equanimity, and so forth, and to the physical health, on the other hand, as smoke is one of the best preservatives known, witness its use for curing bacon."

We do not know whether Dr. Black is here speaking seriously or joking. Nor is it clear whether he is giving his own views or merely reproducing the sophisms of Winzer, the inventor, not indeed of gas, but of gas companies. But the smoke, acids, and stinks still exist as hard facts, chemically and physically demonstrable. The plea concerning the "moral welfare of the consumers," if valid at all would justify every nuisance and nearly every evil. Patience and forbearance are surely not virtues but vices when we are placed face to face with a preventible or avoidable evil. The smoke used in curing bacon and in rendering it less digestible is not coal-smoke, but wood-smoke.

This notion of the sanitary benefits of coal gas is the more strange as, in the next section, the author, speaking of the deadly properties of carbon monoxide, writes:—"Cases of poisoning by coal-gas are, therefore, cases of poisoning by carbonic oxide. These cases are by no means of rare occurrence in large cities."

We trust that in a new edition Dr. Black will see his way to the elimination of his exaggerated praises of coal-gas, the more as it has little connection with his main subject.

The use of carbon disulphide for destroying rabbits—one of the direst plagues in Australia—is an exceedingly happy thought. Phosphorus is also extensively and successfully used in the Australian colonies for the same purpose. In the same chapter the author discusses most judiciously the waste of plant-food which has been and still is committed in all civilised countries save China and Japan. He justly denounces the folly of passing the sewage of our great cities into the sea, as we are doing and apparently intend to do here in London.

Under potassium we find no mention of what are now its chief sources, the Stassfurt group of minerals. It is very desirable that careful search for such minerals should be made in likely localities in India and in the Colonies.

In the section on copper and its ores, the electrolytic assay seems to have been overlooked.

If, in our notice of this work, we have chiefly pointed out what appear to us as errors or oversights, it is by no means due to any desire on our part to depreciate the work. On the contrary, we believe it is, in the main, a highly useful manual, which, after a more thorough revision, will deserve to take a permanent place, as a text-book, in schools of mining and metallurgy.

On the Valuation of Unexhausted Manures. By Sir J. B. Lawes, Bart., F.R.S., and J. H. Gilbert, Ph.D., F.R.S. London: Murray.

The subject of this pamphlet is as full of importance as it is of difficulties. It strikes us in the first place as a deficiency that the authors include, under the head of unexhausted manures, those substances only which have been passed through the bodies of cattle. Of bone-dust, precipitated phosphates, basic iron slags, &c., which may have been applied to the land, say, a year before the expiration of a tenancy, and the value of which may not be entirely exhausted, no account is taken. In three successive chapters the authors discuss and tabulate, first, the average composition of cattle-foods, secondly, the total or original value of consumed cattle-foods, and thirdly, the unexhausted manure value of cattle-foods. They propose, as regards the more nitrogenous foods, to deduct $\frac{1}{2}$ of the original manure value for the last year and $\frac{1}{4}$ from year to year. For hay and straw of whatever kind they deduct $\frac{1}{3}$ of original value the last year and $\frac{1}{6}$ from year to year.

Proceedings of the American Pharmaceutical Association at the Thirty-third Annual Meeting, held at Pittsburgh, September, 1885; Also the Constitution, By-Laws, and Roll of Members. Philadelphia: The Association.

We are first led to notice the list of queries to be answered at the meeting in September next. Among these we notice a question as to the best practical method of determining melting-points; a demand for a plan for the perfect separation of the alkaloids, and for tests for brucine and strychnine when jointly present; and a good process for determining tannin. This last query is one of great interest, but we fear that it will not for some time receive a satisfactory answer.

The section on the Progress of Pharmacy is extensive and contains much important matter, though doubts might arise as to the specially or exclusively pharmaceutical character of some passages. We are glad to observe the scrupulous care of the compilers in stating the original source from which each paragraph or abstract has been obtained.

Considerable attention has evidently been paid to legislation concerning the sale of poisons. The "Pharmacy Law" of Kansas arranges a number of articles in two schedules, in the second of which figure the mineral acids! The sale of these articles, except to "practising physicians and photographers," is encumbered with a variety of formalities. We might suggest that an analytical chemist is surely as much entitled to special consideration as a photographer, and further that the proscription of "poisons" in a country where explosives and ammunition are freely dispensed to all comers is a somewhat needless precaution.

There are further special reports and essays on pharmacy, on chemistry, and on materia medica. In the first-mentioned section there is a note on fungoid growths in dilute phosphoric acid. Singularly enough the same percentage of free acid is found in such acids after the fungus has grown as there was previously.

In the section on chemistry we find a notice of the gross adulteration of stibnite or antimony sulphide. Whilst certain samples consisted of the natural antimony ore in a powdered form, others, in fact nine out of fifteen of the samples, showed "no trace of antimony by the tests of the pharmacopœia," but consisted of coal-dust and powdered limestone!

In the chapter on Materia Medica is a paper on the "Exportation of American Drugs." Here we find a statement doubtless true, but which reflects little credit to the British public. "England led all the other nations in her purchases of (American) patent medicines, having bought the enormous sum of 397,389 dollars' worth."

So in these days the demand for quackery far exceeds the native supply!

CHEMICAL NOTICES FROM FOREIGN SOURCES.

Note.—All degrees of temperature are Centigrade unless otherwise expressed.

Justus Liebig's Annalen der Chemie,
Vol. ccxxxii., Part 3.

Atomic Weights of Cobalt and Nickel.—Clemens Zimmermann (edited by Alibegoff and Krüss).—The author finds for cobalt the atomic weight 58·742 (O = 15·96), or 58·89 if O = 16. The properties of pure cobaltous oxide are given as follows:—The oxide has a light brown colour and is non-magnetic. If heated on platinum foil over a single flame it is rapidly converted into a higher black oxide. Even after two months' exposure to the air it does not undergo the slightest change of weight. The oxide is gradually dissolved by acids, the solution being rose-coloured. Strong hydrochloric and sulphuric acid dissolve it with a blue colour. Ammonia has no action, even in heat. Hot solution of ammonium chloride takes up cobaltous oxide with a deep blue colour, whilst ammonia is liberated. On cooling the liquid assumes a red colour. The behaviour of ammonium sulphocyanide is similar. Dilute alkaline solutions have no action upon cobaltous oxide. Strong potassa or soda-lye, if hot, dissolve cobaltous oxide with a deep blue colour; on dilution with water cobaltous hydroxide is deposited and is quickly oxidised, turning brown. The atomic weight of nickel is = 58·557 if O = 15·96, or 58·705 if O = 16. Nickel monoxide has a fine light green colour and is not magnetic. If heated on platinum foil it takes a deep yellow colour, but the green returns on cooling. In hot hydrochloric acid, strong or weak, the monoxide dissolves with a green colour, without the slightest evolution of chlorine. Nitric acid, if hot, dissolves nickel monoxide with a green colour. Sulphuric acid, with the aid of heat, dissolves nickel monoxide slowly; the solution is yellow. Hot perchloric acid dissolves the monoxide slowly with a green colour; in the cold there is no action. Acetic acid does not dissolve nickel monoxide, even on prolonged boiling. In a solution of ammonium chloride the oxide is also almost insoluble on prolonged boiling, and in ammonium sulphocyanide it is insoluble. The strongest soda-lye, even with the aid of heat, has no action upon nickel monoxide, but it is readily taken up by melting sodium sulphate, forming a dark brown melt which turns yellow on cooling, and dissolves in water with a green colour. By the above researches it is demonstrated that the atomic weights of cobalt and nickel, though closely approximating, are yet not identical. This fact is in accordance with the requirements of the periodic system. As regards the relations of the values 58·742 and 58·557 to Prout's hypothesis, they supply fresh confirmation of its untenable character.

Method for Separating and Determining Zirconium.—Dr. G. H. Bailey.—The preparation of zirconium free from traces of other elements is very difficult, especially in presence of iron, titanium, niobium, and some other rare elements. For the determination of zirconium in minerals which contain it merely in traces there is, hitherto, no good method. It is by no means impossible that zirconium may be more widely diffused in minerals than experience has hitherto shown. Hydrogen peroxide supplies a means of separation. Its very dilute solutions produce no precipitate, but with a moderately concentrated solution the precipitation is perfect. Clève has already shown that it does not throw down iron and alumina. Titanium occasions a colouration from which the formation of a higher oxide may be inferred, but there is no precipitation. From a solution containing titanium salts zirconium may, therefore, be thrown down quite free from titanium. Niobium and tantalum seem, likewise, to form no precipitates with hydrogen peroxide, as is also the case with tin and silicium. The above-mentioned elements are those which generally occur together with zirconium, and are difficult to separate according to the ordinary method. Hydrogen peroxide of such a strength that it yields 120 vols. oxygen, throws down Zr_2O_5 at once and completely from a solution of zirconium in excess of sulphuric acid. The author is engaged with the further study of this method.

Notes on an Analysis of Koppite.—Dr. G. H. Bailey.—The specimen in question was obtained from Kaiserstuhl, and contained niobium, titanium, zirconium, cerium, lanthanum, and didymium, besides iron, calcium, magnesium, sodium, potassium, and fluorine. Thorium was not present.

Some New Vanadium Compounds.—J. T. Brierley.—The author has obtained five salts containining different quantities of the two vanadium oxides V_2O_4 and V_2O_5.

Die Chemische Industrie.
Vol. ix., No. 3, March, 1886.

The Application of the Spectroscope in the Manufacture of Aniline Colours.—Dr. Paul Schoop.—The author recommends quantitative spectral analysis as the best method for ascertaining the tinctorial strength and the tone of a colouring-matter. He proposes a simpler and less costly modification of the apparatus of Krüss. He considers that spectral analysis will solve certain very important theoretical questions, *i.e.*, ascertain the influence of a substituted radicle or of certain groups of atoms upon the intensity of a colour.

Journal de Pharmacie et de Chemie.
Series 6, Vol. xiii., No. 9, May 1, 1886.

The Oxidation of Sebacic Acid.—H. Carette.—The oxidation of sebacic acid yields succinic, adipic, and iso-pyrotartaric acid.

Detection of Coal-Tar Reds in Wines by means of Metallic Oxides.—P. Cazeneuve.—Already noticed.

A New Tannin.—The use of valonia nuts appears to be rare or unknown in France, though common in the rest of Europe.

Detection of Cochineal, Phytolacca decandra, Beetroot, and Orchil in Wines.—M. Bellier.—For the three former colouring-matters the author employs an intimate and finely powdered mixture of stannous chloride and borax, both previously dried. For orchil the reagent is a similar mixture of borax and of lead acetate. The method of operation is as follows:—About 10 c.c. of wine are poured into a test-tube, and a pinch of the tin-borax mixture is added. The whole is shaken up, heated to a boil, and filtered. If neither cochineal, *Phytolacca*, nor beet-root is present, the filtrate is colourless or faintly yellow. If it contains any of the three, it is more or less deeply red. To distinguish cochineal from the two others a few drops of ammonia are added to the filtrate, and the mixture is boiled. Cochineal is thus turned to a more violet tone, whilst *Phytolacca* and beet-root are decolourised and become yellow. If the filtrate has only a faint rose-colour, instead of ammonia there are added to it a few drops of sulphuric acid, a little amylic alcohol, and the whole is shaken up. The cochineal passes into the amylic alcohol and colours it red: the *Phytolacca* and beet-root do not pass over, and the amylic alcohol remains colourless. For the detection of orchil the author proceeds in exactly the same manner. Wine coloured with orchil has, after treatment and filtration, a violet colour. Natural wine runs through the filter colourless or slightly yellowish. In examining an unknown wine the tin-borax reaction should be tried first, and, before both reactions, it is well to ascertain with the mixture of mercuric acetate and magnesia that no coal-tar colour is present.

The "Velo-Porphyre," a New Pharmaceutical Apparatus. — B. Giraud. — The apparatus in question cannot be intelligibly described without the two accompanying figures.

Moniteur Scientifique, Quesneville.
3rd Series, Vol. xvi., May, 1886.

Review of various Chemical Researches.—Abstracts of papers from the Chemical News.

The Derivatives of Hexa-oxybenzine and their Relations with Croconic and Rhodizonic Acids.—MM. Nietzki and Benckiser.—From the *Berichte der Deutsch. Chem. Gesellschaft.*

Enrichment of Coal-Gas with Certain Hydrocarbons.—G. E. Davis.—A paper read read before the London Section of the Society of Chemical Industry, Jan. 4, 1886.

Explosion of Homogeneous Gaseous Mixtures.—Dugald Clerk.—A paper read at the meeting of Civil Engineers, Feb. 9, 1886.

Agreement entered into by the Manufacturers of Manures and the Agricultural Stations of South Germany for Converting and Unifying the Bases of the Determination of the Commercial Value of Superphosphates and Precipitated Phosphates.—Professor Paul Wagner.— From the *Chemiker Zeitung*, 1886, pp. 1, 19, 37. It has also appeared in the Chemical News, liii., p. 133.

Notes on Quinine Hydrate.—F. W. Fletcher.

Cocaine and its Salts.—Dr. B. H. Paul.—These two papers have evidently appeared in some English journal.

Attempt at a Qualitative Analysis of the Colouring-Matters met with in Commerce.—Dr. O. N. Witt.—Already noticed under *Chemische Industrie*, from which it has been translated.

Artificial Colouring-Matters applied in Manufactures. — (Fourth Lecture). — Dr. E. Noelting. — This lecture is devoted to the phthaleines and to artificial indigo. The lecturer admits that the problem of an artificial indigo, capable of competing with the natural product, has not yet been solved.

On Electrolytic Theories. — G. Chicandard. — An abstract of a memoir by Prof. Gonzalvo Guimaraes, of the University of Coimbra. The author admits that the chemical atoms are aggregates of elementary atoms, equal among themselves and possessing the same quantity of *vis viva*, and that the laws which govern the combinations of chemical atoms govern likewise the aggregations of chemical atoms. From *à priori* considerations he arrives at the following conclusion: the force necessary to decompose a compound molecule is the same as that which dissociates any other molecule whatever provided that the radicles of each are of the same atomicity. Thus, when a current traverses two voltameters containing, the first a solution of ferric sulphate and the second one of aluminium sulphate, the weights of each electrolyte decomposed in a given time are as their respective molecular weights. Thus the quantity of electricity sufficient to decompose the molecule of aluminium sulphate will decompose 3 mols. zinc sulphate, 3 mols. potassium sulphate, or 6 mols. potassium nitrate. These considerations render it possible to establish the two following propositions, which both agree with the electrolytic law:—1. When an electric current traverses several electrolysible substances the ponderable quantity decomposed is, for each of them, proportional to the molecular weight and inversely proportional to the atomicity which the ions had in the molecule. 2. Each *electro-atomy* decomposes a fraction of molecular weight of which the numerator is equal to unity and the denominator to the atomicity which the ions had in the molecule. The author proposes the word *electro-atomy* as a substitute for that of "equivalent of electricity," which he regards as belonging to an obsolete notation. According to Prof. Guimaraes these two propositions are applicable not merely to the oxides and metallic salts, but to all compounds, inorganic or organic, of which the electrolysis has been effected.

Industrial Society of Mulhouse: Chemical Committee.—Session of March 10.—M. Weber communicated the sequel of his researches on the red colouration taken by pieces of cotton exposed to the vapours of commercial aniline. He finds that pieces which, in the raw state, are of the deepest colour take the most decided rose tint. The red colour upon bleached calico is, strange to say, the more decided the more thoroughly it has been treated with chlorine in bleaching. A cloth which has undergone all the other operations of bleaching without chlorine does not show this colour. The rose tint does not come from traces of chlorine remaining in the tissue, since it is produced with equal intensity if, after the last chlorination, it is taken through sodium bisulphite. An energetic treatment with soda at a boil after the chlorine prevents the reddening entirely. The chlorinised tissue which reddens under the influence of aniline vapours is found to have acquired the property of attracting basic colours more strongly than ordinary cotton, whilst it manifests no affinity for dyes of an acid or phenolic character.

G. Galland sent in researches on the colours derived from benzidine, with reference to their power of acting as mordants for the basic colours.

Supplementary Session, March 26.—C. Kœchlin, with reference to Schœn's paper on apparatine, remarked that very strong soda-lyes do not affect starch, which dissolves in dilute lyes.

M. Dépierre sent in a paper on the manufacture of white-metal cylinders for printing, covered with copper by the galvano-plastic process.

L. Durand, of the firm Durand and Huguenin, of Bâle, addressed to the committee a letter on the history of resorcine green.

Preparation of Sublimed Oxalic Acid.—H. Hussenot.—The author proposes a modification of Hampe's process.

MEETINGS FOR THE WEEK.

Wednesday, 16th.—Meteorological, 7.
Thursday, 17th.—Chemical, 8. Ballot for the Election of Fellows. (For List of Papers to be read see p. 284).
— Royal Society Club, 6.30. (Anniversary).

CITY AND GUILDS OF LONDON INSTITUTE,
CENTRAL INSTITUTION, EXHIBITION ROAD, S.W.

SUMMER COURSES OF LECTURES
AND LABORATORY INSTRUCTION.

1. On the Teaching of Chemistry as introductory to its Technical Applications. by Professor Armstrong, F.R.S., Ph.D. This Course will extend over two weeks, from 10 to 5 daily, Saturdays excepted, commencing on Monday, July 5th. Fee £2.

2. On Candle Manufacture and the Treatment of the By-Products. Four Lectures by Leopold Field, F.R.S.E., on July 5th, 6th, 8th, and 9th, at 7.30 p.m each day. Fee 5s.

3. On the Chemistry of Tanning. Four Lectures, with experimental illustrations, by Henry R. Procter, F.C.S., on July 12th, 13th, 15th, and 16th, at 7.30 p.m. Fee 5s.

4. On the Technology of Cellulose and Paper Manufacture. Four Lectures by C. F. Cross, Esq., F.C.S., assisted by E. T. Bevan, Esq., F.C.S., on July 19th, 20th, 22nd, and 23rd, at 7.30 p.m. Fee 5s.

5. On Building Materials. Four Lectures by W. G. Dent, F.C.S., F.I.C., on July 26th, 27th, 29th, and 30th, at 7.30 p.m. Fee 5s.

Further particulars and Syllabus of each Course may be obtained at the Central Institution, Exhibition Road, S.W., or at Gresham College, London, E.C.

Registered Teachers of the Institute may, on application, be admitted to these Courses without payment of fees.

PHILIP MAGNUS.
Director and Secretary.

THE CHEMICAL NEWS.

Vol. LIII. No. 1386.

THE SUPPOSED ERROR IN THE NITROMETRIC ASSAY OF VITRIOL.

By G. LUNGE.

In his last communication (Chemical News, vol. liii., p. 266) Mr. Thomas Bayley admits that he was mistaken in attributing the power of retaining nitric oxide to the solution of mercurous sulphate in sulphuric acid, contained in the nitrometer. But he still upholds that an error is committed, owing to the presence of *iron*. In support of this he quotes several experiments, made with solutions of ferrous sulphate in pure concentrated sulphuric acid, and one with a sample of Glover acid, containing 0·05 per cent Fe. Unfortunately it did not occur to him to try that substance which alone was in question, viz., nitrous vitriol, or indeed anything containing either nitrous or nitric acid *beforehand*, instead of mixing the substances only within the nitrometer. He would then have found that no error could possibly have arisen from the presence of iron, since only proto-salts of iron dissolve NO, and no proto-salt of iron can exist in the presence of nitrous or nitric acid! That the "pure" concentrated sulphuric acid added in the experiment should in any practical case contain an appreciable quantity of iron, sufficient to dissolve NO, is a most unlikely assumption, for which not a tittle of proof is given, and that this iron should exist in the shape of proto-salt is still more bordering on the impossible. Anything of the kind would be shown by the brown colour of NO dissolved in $FeSO_4$, which Mr. Bayley himself points out as an extremely delicate reaction, but which I, for my part, have never observed in testing nitrous vitriol, and of which Mr. Bayley himself, no more than anybody else, has ever spoken as occurring in that case. If it did occur such a test would, of course, be rejected.

For the future I must decline to waste your readers' and my own time with a subject worn threadbare now. If there is anybody still convinced that Mr. Bayley has proved the alleged error in using the nitrometer, I leave him to his belief.

Although I am no lover of priority disputes, I do not like passing over the way in which Mr. Bayley seeks to detract from my little merits concerning the nitrometer. He talks of "the original (Davis's) two-way nitrometer, and the three-way instrument (introduced by Lunge)." The simple facts of the case are these:—The principle of the method in question has been indicated by W. Crum a very long time ago, and later on it has been used by Frankland and Armstrong, who employed a tube open at the bottom, at the top surmounted by a simple stop-cock and cap. Mr. G. E. Davis drew attention to this method for the testing of nitrous vitriol, but he continued using the Frankland tube, with a somewhat smaller mercury-trough. In this shape Crum's method was still very inconvenient, certainly unfit for general introduction among technical chemists, especially as nobody had taken the trouble to verify whether it yielded accurate results with such substances as it is now principally employed for. I supplied the deficiency by devising a piece of apparatus which dispenses with a mercury-trough, which admits of much easier—and yet decidedly more accurate—manipulation than the Frankland tube, and with which, by means of the three-way cock, you may finish a test, clean out the tube, and be ready for the next test in a few minutes. I also took the trouble of proving, by methods devised by myself, that the method and its manipulation is accurate for the testing of commercial, impure, nitrous vitriol. Lastly, I invented for my offspring the name "Nitrometer." All this I published in the *Berliner Berichte*, vol. xi., p. 436, the date of arrival at Berlin being stated —March 6, 1878 (*comp.* Chemical News, July 12, 1878, vol. xxxviii., p. 19). A couple of months after this, when travelling in England, I met Mr. G. E. Davis, and saw him using the same apparatus he had previously described —that is, a Frankland tube in a mercury-trough, nothing else. Only in 1882 (June 5th) Mr. W. J. Lovett described, in the *Journal of the Society of Chemical Industry*, 1882, p. 211, an apparatus, somewhat similar to mine, as "Davis's Nitrometer." Previously to this, but nine months after me,—on December 19th, 1878,—Mr. Starks had also described a "Nitrometer" (avowedly borrowing my word) in the *Transactions of the Newcastle Chemical Society*, vol. iv., p. 189 (Chemical News, April 18, 1879, vol. xxxix., p. 168). Now I do not object to Messrs. Davis and Starks adopting a name invented by me; nor do I mean to tax these gentlemen with having borrowed my idea, which, indeed, they would have done very imperfectly, as Davis's two-way cock is a great step backwards against my three-way cock, and Starks's instrument wants a "level-tube." I do not doubt that they had used their apparatus before they became aware of my publication; but I must insist that the "original nitrometer," both in name and in substance, is *mine*, and that Davis's and Starks's less perfect instruments were given to the world, and presumably invented later than mine.

Zürich, June 9, 1886.

PEROXIDES OF POTASSIUM AND SODIUM A LECTURE EXPERIMENT.

By H. CARRINGTON BOLTON.

The peroxide of potassium, K_2O_4, and the peroxide of sodium, Na_2O_2, were known to Gay-Lussac and Thénard* as early as 1810, by whom they were obtained in minute quantities in various ways. They have been analysed and closely studied by Vernon Harcourt,† who prepared them by burning the respective metals in dry oxygen gas.

I have devised a simple method for exhibiting to a class the formation and some of the characteristics of these peroxides. In a test-tube suspended by a wire from an iron stand, a quantity of potassium nitrate is melted over a Bunsen burner, and heated until oxygen gas is freely liberated; on dropping into the melted nitrate small pellets of clean potassium, the metal burns with a bright light, and forms the yellowish peroxide: this gradually sinks beneath the surface of the melted mass and dissolves therein, communicating to the whole a deep, rich, red colour: the colour is easily shown by the aid of transmitted light. On allowing the melted mass to cool and solidify, the colour disappears, but reappears on again applying heat.

If sodium nitrate and metallic sodium be used similar phenomena are observed, but the solution of the peroxide has a yellowish red colour. The action of sodium on melted saltpetre produces a brown-red solution quite intense when sufficiently heated. On cooling, in each case the mass loses its colour.

These reactions are quite consistent with the properties of the peroxides as described by Harcourt. Potassium peroxide, he says, is "deep orange-yellow, and fuses to a black fluid"; sodium peroxide is white when cold, becomes "full yellow" on heating, and when fused is "black while hot, brown on cooling." Moreover we prepared a small quantity of sodium peroxide in the usual way, by burning the metal in dry oxygen, and ascertained that it dissolves in melted saltpetre with the characteristic colouration.

* "Recherches Physico-Chimiques," i., 132.
† *Quart. J. Chem. Soc.*, xvi., 267 (1861).

The colourless mass resulting from any of the above reactions forms, of course, a strong alkaline aqueous solution: this yields, with copper sulphate, a greenish precipitate which is evidently a mixture of blue cupric hydrate and of the yellow peroxide of copper, formed, according to Brodie, when alkaline peroxides react on salts of copper.*

On attempting to examine the action of sodium on melted chlorate of potassium a violent explosion occurred, projecting fragments of the test-tube and the melted salt into the face and over the person of the operator. The explosion was instantaneous, and accompanied by a loud report. On repeating this with suitable precautions, using a stouter tube surrounded by a metallic cylinder, similar explosions resulted, without, however, breaking the glass. Pellets of sodium no larger than a grain of barley cause sharp reports the moment they reach the surface of the melted chlorate. Serious accidents might result from incautious experimentation with these materials should the treacherous character of chlorates be overlooked.

As a lecture experiment the action of potassium on the nitrate is instructive, and will do much to dispel the impression, often left on the minds of students, that the alkaline metals form coloured compounds only with acids having chromatic radicals.

ON THE PLACE OF ORIGIN OF URIC ACID IN THE ANIMAL BODY.†

By ALFRED BARING GARROD, M.D., F.R.S.

The endeavour of the author in this communication has been to show the place of origin of uric acid in the animal body, and to ascertain which of the two hypotheses on the subject is correct, viz., whether uric acid is first present in the blood and then secreted from the blood by the kidneys, or whether it is formed by the kidneys themselves. To enable him to satisfactorily prosecute many of his observations the author has devised a new method for discovering the presence of uric acid in very minute quantities of blood.

The results of his investigations are embodied in the form of the nine following propositions:—

Prop. I.—Uric acid is secreted by the kidneys as ammonium urate, and in the case of birds and reptiles, whose urine is semi-solid, it is found in a definite physical form, more in the vitreous condition than in the truly crystalline shape.

Prop. II.—Uric acid, when present in the blood, is found under the form of sodium urate, and, when deposited from the blood during life in any tissue, it is also as sodium urate in its characteristic crystalline form.

Prop. III.—The daily quantity of uric acid in relation to their body-weights secreted by different animals varies extremely. In some, as the carnivorous mammalia, the ratio may be less than 1 to 1,000,000, whereas, in others, as birds, it may be as 1 to 85. In man it may be regarded as about 1 to 120,000.

Prop. IV.—The quantity of uric acid contained in the blood of different animals has little relation to that secreted by the kidneys. In birds, secreting daily so large a quantity, the blood is often found to be as free from uric acid as it is in animals whose daily elimination of uric acid is excessively small.

Prop. V.—When uric acid is absorbed from the alimentary canal the blood becomes strongly impregnated, and, in fact, often almost saturated with it, so that its presence is readily discovered by any ordinary test.

Prop. VI.—One cause of the appearance of an unusual quantity of uric acid in the blood of birds in health is the presence of uric acid in the water they drink, and occasionally in their solid food.

Prop. VII.—When uric acid is taken into the stomach of man, or other animals, the secretion of this principle from the kidneys is not increased, although at the time the blood may be rich in it.

Prop. VIII.—Uric acid is found in varying quantities in the blood obtained from different veins in the same animal. It is found in larger quantity in that from the efferent renal veins than in that from the portal afferent, or from the jugular veins; and the same test which freely exhibits uric acid in the blood from the former, often fails to show it at all in that from the latter two.

Prop. IX.—The quantity of uric acid secreted daily by the kidneys of a bird is in close relation to the quantity of nitrogenised food taken during the time.

Having brought forward proofs to confirm these propositions severally, the author draws the following conclusion, viz., that every argument is in favour of the hypothesis that uric acid is formed by the kidney-cells, in the form of ammonium urate, and that the traces of sodium urate found in the blood are the result of a necessary absorption, slight in amount, of the ammonium urate from the kidneys into the blood, and its subsequent conversion in that fluid into sodium urate.

FLAME CONTACT.
A NEW DEPARTURE IN WATER HEATING.*

By THOMAS FLETCHER, F.C.S.

It is my intention to prove to you, on theoretical grounds, and also by experimental demonstration, in such a manner as will admit of no possible doubt, that the present accepted system of water heating, by gaseous or other fuel, is a very imperfect means for an end, and is, both in theory and practice, essentially faulty. My statements may appear bold, but I come prepared to prove them in a manner which I think none of you will question, as the matter admits of the simplest demonstration. I will, in the first place, boil a specified quantity of water in a flat-bottomed vessel of copper; the time required to boil this you will be able to take for yourselves, as the result will be visible by the discharge of a strong jet of steam from the boiler. I will then take another copper boiler of the same form, but with only one-half the surface to give up its heat to the water, and will in this vessel boil the same quantity of water with the same burner in a little over one-half the time, thus about doubling the efficiency of the burner, and increasing the effective duty of the heating surface nearly four-fold, by getting almost double the work from one-half the surface.

The subject is a comparatively new one, and my experiments are far from complete on all points, but they are sufficiently so to prove my case fully. As no doubt you are all aware, it is not possible to obtain flame contact with any cold, or comparatively cold, surface. This is readily proved by placing a vessel of water with a perfectly flat bottom over an atmospheric gas-burner; if the eye is placed on a level with the bottom of the vessel a clear space will be seen between it and the flame. I cannot show this space on a lecture table to an audience, but I can prove its existence by pasting a paper label on the bottom of one of the boilers, and exposing this to the direct impact of a powerful burner during the time the water is being boiled, and you will see that it comes out perfectly clean and uncoloured. Now it is well known that paper becomes charred at a temperature of about

* *Proc. Roy. Soc.*, xii., 209.

† Abstract of a Paper read before the Royal Society, June 10, 1886.

* Gas Institute Meeting, London, June 9th, 1886.

400° F., and the fact that my test-paper is not charred proves that it has not been exposed to this temperature, the flame being in fact extinguished by the cooling power of the water in the vessel. I need hardly remind you that the speed with which convected or conducted heat is absorbed by any body is in direct ratio to the difference between its own temperature and that of the source of heat in absolute contact with it; and, therefore, as the source of the heat taken up by the vessel is nothing but unburnt gases, at a temperature below 400° F., the rate of absorption cannot, under any circumstances, be great, and the usual practice is to compensate for this inefficiency by an enormous extension of surface in contact with the water, which extension I will prove to you is quite unnecessary. You will see I have here a copper vessel with a number of solid copper rods depending from the lower surface; each rod passes through into the water space and is flattened into a broad head, which gives up its heat rapidly to the water. My theory can be stated in a few words: The lower ends of the rods, not being in close communication with the water, can, and do attain, a temperature sufficiently high to admit of direct flame contact, and as their efficiency, like that of the water surface, depends on the difference between their own temperature and that of the source of heat in absolute contact with them, we must, if my theory is correct, obtain a far greater duty from them. I do not wish you to take anything for granted, and although the surface of the rods, being vertical, can only be calculated for evaporating power at one half that of a horizontal surface, as is usual in boiler practice, my margin of increased duty is so great, that I can afford to ignore this, and to take the whole at what its value would be as horizontal surface, and still obtain a duty 50 per cent greater from a surface which is the same in area as the flat-bottomed vessel on the fire side, but having only one-third the surface area in contact with the water. I do not, of course, profess to obtain more heat from the fuel than it contains, but simply to utilise that heat to the fullest possible extent by the use of heating surfaces, beyond comparison smaller than what have been considered necessary, and to prove not only that the heating surfaces can be concentrated in a very small area, but also that its efficiency can be greatly increased by preventing close water contact, and so permitting combustion in complete contact with a part of the heating surface. I will now boil 40 ounces of water in this flat-bottomed copper vessel, and, as you will see, sharp boiling begins in 3 minutes 15 seconds from the time the gas is lighted. The small quantity of steam evolved before this time is of no importance, being caused partly by the air driven off from the water and partly from local boiling at the edges of the vessel owing to imperfect circulation. On the bottom of this vessel is pasted a paper label which you will see is untouched by the flame owing to the fact that no flame can exist in contact with a cold surface.

It may be thought that, owing to the rapid conducting power of copper, the paper cannot get hot enough to char. This is quite a mistake, as I will show you by a very curious experiment. I will hold a small plate of copper in the flame for a few seconds, and will then hold it against the paper. You will see that, although the copper must of necessity be at a temperature not exceeding that of the flame, it readily chars the paper. We can, by a modification of this experiment, measure the depth of the flameless space, as the copper, if placed against the paper before it has time to be previously heated, will, if not thicker than 1-40th inch, never become hot enough to discolour the paper, showing that the flame and source of heat must be below the level of a plate of metal this thickness.

In repeating this experiment I must caution you to use flour paste, not gum, which is liable to swell and force the paper past the limit of the flameless space, and also to allow the paste to dry before applying the flame, as the steam formed by the wet paste is liable also to lift the paper away and force it into the flame. I will now take this vessel, which has only one-half the surface in contact with the water, the lower part being covered with copper rods, 3-16th inch diameter, ¼ inch centres apart, and 1¼ inch long, and you will see that with the same burner as before, under precisely the same conditions, sharp boiling takes place in 1 minute 50 seconds, being only 13 seconds more than half the time required to produce the same result with the same quantity of water as in the previous experiment. Although the water surface in contact with the source of heat is only one-half that of the first vessel and the burner is the same, we can see the difference not only in the time required to boil the 40 oz. of water, but also in the much greater force and volume of steam evolved when boiling does occur. With reference to the form and proportions of the conducting rods, these can only be obtained by direct experiment in each case for each distinct purpose. The conducting power of a metallic rod is limited, and the higher the temperature of the source of heat, the shorter will the rods need to be, so as to ensure the free ends being below a red heat, and so prevent oxidation and wasting. There are also other reasons which limit the proportions of the rods, such as liability to choke with dirt and difficulty of cleaning, and also risk of mechanical injury in such cases as ordinary kettles or pans; all these requirements need to be met by different forms and strengths of rods to ensure permanent service, and, as you will see further on, by substituting in some cases a different form and type of heat conductor. To prove my theory as to the greater efficiency of the surface of the rods in contact with the flame as against that in direct contact with the water, I have another smaller vessel which, including the rods, has the same total surface in contact with the flame, but only one-third the water surface as compared with the first experiment. Using again the same quantity of water and the same burner we get sharp boiling in two minutes ten seconds, being an increase of duty of 50 per cent, with the same surface exposed to the flame. The rods in the last experiment form two-thirds of the total heating surface, and if we take, as I think for some careful experiments we may safely do, one-half the length of the rods to be at a temperature which will admit of direct flame contact, we have here the extraordinary result that flame contact with one-third of the heating surface increases the total fuel duty on a limited area 50 per cent. This really means that the area in contact with flame is something like six times as efficient as the other. In laboratory experiments it is necessary not only to get your result, but to prove your result is correct, and the proof of the theory admits of ready demonstration in your own laboratories although it is unfit for a lecture experiment, at all events in the only form I have tested it. If you will take two ordinary metal ladles for melting lead, cover the lower part of one of these with the projecting rods or studs and leave the other plain, you will find on melting a specified quantity of metal in each that the difference in duty between the two is very small. The slight increase may be fully accounted for by the difference in the available heating surface reducing the amount of waste heat passing away, and this proves that flame contact, and therefore quick absorption of heat, takes place on plain surfaces as soon as these are above a certain temperature, which, in a metal ladle, very soon occurs. What the temperature is which admits of flame contact I have, as yet, not been able to test thoroughly, and it will need some consideration how the determination of this is to be correctly made; at the same time it is a question in physics which should be capable of being answered.

Let us now take the other side of the question. If the efficiency of a surface depends on flame contact there must of course be flame, or at least gases of an extremely high temperature, and we therefore cannot expect this extraordinary increase of efficiency in any part of our boiler except where flame exists, and if these projectors are placed in a boiler, anywhere except in contact with

flame, their efficiency must be reduced to that of ordinary heating surface. They are, of course, useful, but only in the same way as ordinary flue surface. When we come to boilers for raising steam, which have to stand high pressures, we come to other difficulties of a very serious nature, which require special provision to overcome them. To put such rods as I have referred to in a boiler-plate necessitates the plate being drilled all over holes, causing a dangerous source of weakness, as the rods cannot be used as stays; further than this, they would render really efficient examination a matter of extreme difficulty, and would be liable to give rise to frequent and almost incurable leakages; but there is, fortunately, a very simple way to overcome this difficulty. I have found that rods or points, such as I have described, are not necessary, and that the same results can be obtained by webs or angle-ribs rolled in the plates. My experiments in this direction are not complete, and at present they tend to the conclusion that circular webs, which would be of the greatest efficiency in strengthening the flues, are not so efficient for heating as webs running lengthwise with the flue, and in a line with the direction of the flame. This point is one which I am at present engaged in testing with experimental boilers of the Cornish and Lancashire type, and as, with gas, we have a fuel which renders every assistance to the experimenter, it will not take long to prove the comparative results obtained by the two different forms of web. Those of you who have steam boilers will, no doubt, know the great liability to cracking at the rivet-holes in those parts where the plates are double. This cracking, so far as my own limited experience goes, being usually, if not always, on the fire side, where the end of the plate is not in direct contact with the water,—where it is, in fact, under the conditions of one of the proposed webs,—I think we may safely come to the conclusion that this cracking is caused by the great comparative expansion and contraction of the edge of the plate in contact with the fire; and it will probably be found that if the plates are covered with webs, the whole of the surface of the plates will be kept at a higher and more uniform temperature, and the tendency to cracks at the rivet-holes will be reduced. This is a question not entirely of theory, but needs to be tested in actual practice.

There is another point of importance in boilers of the locomotive class, and those in which a very high temperature is kept in the fire-box, and this is the necessity of determining by direct experiment the speed with which heat can safely be conducted to the water without causing the evolution of steam to be so rapid as to prevent the water remaining in contact with the plates, and also whether the steam will or will not carry mechanically with it so much water as to make it objectionably wet, and cause priming and loss of work by water being carried into the cylinders. I have observed in the open boilers I use, that when sufficient heat is applied to evaporate one cubic foot of water per hour from one square foot of boiler surface, the bulk of the water in the vessel is about doubled, and that the water holds permanently in suspension a bulk of steam equal to itself. I have, as yet, not had sufficient experience to say anything positively as to the formation or adhesion of scale on such surfaces as I refer to, but the whole of my experimental boilers have up to the present remained bright and clean on the water surface, being distinctly cleaner than the boiler used with ordinary flat surfaces. It is, I believe, generally acknowledged that quick heating and rapid circulation prevents, to some extent, the formation of hard scale, and this is in perfect accord with the results of my experiments. The experiments which I have shown you, I think, demonstrate beyond all question that the steaming power of boilers in limited spaces, such as our sea-going ships, can be greatly increased; and when we consider how valuable space is on board ship the matter is one worthy of serious study and experiment. It may be well to mention that some applications of this theory are already patented.

I will now show you as a matter of interest in the application of coal gas as a fuel how quickly a small quantity of water can be boiled by a kettle constructed on the principle I have described, and to make the experiment a practical one I will use a heavy and strongly made copper kettle which weighs 6½ lbs., and will hold when full one gallon. In this kettle I will boil a pint of water, and, as you see, rapid boiling takes place in 50 seconds. The same result could be attained in a light and specially made kettle in 30 seconds, but the experiment would not be a fair practical one, as the vessel used would not be fit for hard daily service, and I have therefore limited myself to what can be done in actual daily work rather than laboratory results, which, however interesting they may be, would not be a fair example of the apparatus in actual use at present.

ON THE

DETECTION OF ADULTERATIONS IN OILS.

By OSCAR C. S. CARTER.

THE chemical examination of oils is a very important though much neglected study,—important from the fact that the oils which command a high price in the market and are in general demand are frequently adulterated. The temptation to adulterate is great on account of the heavy increase in profit, and because the adulterant is often very difficult of detection. The purchaser is always at the mercy of the oil merchant, unless the oil be submitted to a chemical examination. "Our former Consul at Naples reported to the State Department that immense quantities of refined cotton-seed oils are sent to Italy for the express purpose of sophisticating the native olive oil, for the reason that it can be brought to Naples and sold at less than half the cost of producing pure olive oil." The cotton-seed oil mixed with pure olive oil is exported to other countries. The price of fine salad oil is from 3 to 4 dollars per gallon, while cotton-seed oil is worth from 70 to 90 cents per gallon. The oils commonly used to adulterate olive oil are colza oil, sesame oil, and peanut oil. In the North of France poppy oil is used frequently because of its cheapness and neutral taste, and in Provence honey is used. In all probability glucose syrup has been tried. Linseed oil, the most important drying oil in the arts, so much used in varnishes and paints, is very often sophisticated. Even the seed from which the oil is made is mixed with other seeds. In India flax seed is grown with mustard and rape. In Russia various proportions of hemp and linseed are sown together. Hemp seed yields an oil of an acrid odour, mild taste, and yellow colour, used in Russia for burning in lamps, and making paints, varnishes, and soap. The oils commonly mixed with linseed oil are niger, cotton-seed, fish, rosin, and coal oils. In this country lard is adulterated with palm-nut and cocoanut oil; the latter is a white fat, with the peculiar smell of the kernel. It was formerly made by grinding the kernel, boiling the water, and subjecting the paste to a great pressure: a large quantity of milky juice is so obtained, which is slowly boiled, and the oil separates and is skimmed off. Twenty ordinary sized nuts yield about 2 quarts of oil. The strong taste of these oils is an objection, and may prevent their general use as adulterants and for the manufacture of oleomargarine. Lard oil, which is obtained from lard, is very valuable as a lubricant for machinery, and is also used for greasing wool in spinning. It is frequently adulterated with fish oils and cotton-seed oils. Lard oil is worth 1 dollar and 20 cents per gallon, while cotton-seed oil is worth about one-half as much.

The chemical analysis and detection of the adulterated oil is sometimes simple, but generally it is a difficult and trying task, especially when three or more oils have been mixed. The determination of the percentage of oil used

to adulterate is out of the question, and we must often be satisfied by simply proving that there has been a mixture without knowing the nature of it. But little work has been done on oils compared to the vast amount of research given to other subjects. Chemists have avoided the study and analysis of oils as difficult and uninteresting. We owe almost all we know to the labours of Chevreul, and later to the researches of Prof. Allen and others. When oils are examined, chemical tests are the more important, but the physical tests are also very useful. At the present time we have not a characteristic test for each oil, as we have for each metal, that will distinguish it when mixed with other oils or that will identify it when alone.

When we examine an oil supposed to be adulterated, much can be accomplished by procuring a sample of perfectly pure oil, and subjecting them both to the same tests and observing their behaviour. A sample of lard oil supposed to be adulterated was received from a woollen manufacturer for examination. A specimen of perfectly pure lard oil was obtained, and they were subjected to the same tests.

According to Prof. Bechi, of Florence, the following test is reliable and delicate for detecting cotton-seed oil in olive oil: the reagent is a 1 per cent solution of nitrate of silver in absolute alcohol:—Place 5 c.c. of the suspected oil in a glass flask; add to it 25 c.c. of absolute alcohol and 5 c.c. of the test solution of nitrate of silver, made as stated above. The flask is heated in a water-bath at 84° C. (direct heat must not be used). If there be any cotton-seed oil present the mixture will begin to darken, the most minute quantity serving to discolour, and the tint assumed will depend upon the amount of cotton-seed oil present. The test depends upon the fact that cotton-seed oil will reduce nitrate of silver, but olive oil will not. This reduction is also caused by rape-seed oil, but, according to Bechi, pure olive oil will remain without discolouration under this test. While experimenting with the test I thought it might be of service in detecting cotton-seed oil in lard oil; accordingly the sample of chemically pure lard oil was treated with absolute alcohol and nitrate of silver as directed, and then heated: there was not the slightest discolouration of the pure lard oil; even on standing for two weeks it did not darken, thus proving it had no action upon the nitrate of silver. The lard oil obtained from the woollen manufacturer was then tested in the same manner: when it had been heated for a few minutes it began to darken, and finally became quite black, thus proving that the lard oil was not pure, but mixed with some other oil. I am not certain that the darkening is due to reduction; having made a series of experiments with salts of mercury, copper, and antimony, and cotton-seed oil, to see if there would be any reduction, I obtained no satisfactory results, and no reduction was noticed.

The elaidin test is sometimes very satisfactory, especially in detecting a mixture of a drying and non-drying oil, and detecting adulteration of olive oil. This test depends upon the fact that olein and oleic acid in contact with peroxide of nitrogen yield a crystalline, solid, fatty body, fusible at 32° C., to which Boudet has given the name Elaidin. The nitrous vapours made by the action of nitric acid on copper are passed through the oil, or it may be shaken with a fresh solution of mercurous nitrate, which has the property of retaining nitrous acid. Non-drying vegetable oils and most animal fats contain oleic acid. The following oils contain a high percentage of olein: olive, almond, rape, arachis (earth-nut), castor, and the oils from lard and tallow. These oils form, with nitrogen peroxide, solid elaidin of a white or yellow colour, which in some cases is firm and resonant. The drying oils—such as linseed, hemp-seed, and poppy-seed oils—do not form solid elaidin with nitrous vapours, but remain liquid for more than two days, and become slightly coloured. The elaidin test was applied to the adulterated lard oil and to the pure lard oil by adding an equal amount of nitric acid (sp. gr. 1·40) and some copper turnings. The elaidin produced by the pure oil was more firm and coherent than that of the adulterated oil, and was of a lighter colour; also the nitrous fumes rose more rapidly through the pure oil. One curious fact noticed about the adulterated lard oil was, it could not be completely saponified with caustic soda; even when the latter was added in excess, a clear layer of unsaponified oil remained after several trials. This test clearly indicated adulteration, as pure lard oil will completely saponify with caustic soda. Prof. Allen has proved that shark-liver oil and African fish oil resist saponification. He tried to saponify the former oil with aqueous potash, with a solution of potash in absolute alcohol, and by heating it with solid potash, but it would not completely saponify: this he thinks is due to the fact that it contains a body allied to cholesterin, but fluid at ordinary temperatures.

Pure lard oil gives, with nitric acid of sp. gr. 1·33, a yellow colour, approaching orange.

The adulterated sample of lard oil with nitric acid of the same strength gave a distinct brown colour on standing. That portion of the oil which resisted saponification with caustic soda was treated with nitric acid, and it soon became of a deep coffee-brown colour, much darker than the above.

The determination of specific gravity is the most important of the physical tests. The viscosity of an oil is a highly important feature, but in order to be of any value in testing much care must be observed; both oils must be brought to the same temperature, and kept so while flowing. Both the adulterated and the pure lard oil were subjected to this test; they were brought to a temperature of 80° F., and 5 c.c. of each oil were passed through a capillary tube. The pure oil required 960 seconds to pass through, while the adulterated oil required 1080 seconds. The experiment was repeated several times with different tubes, but the ratio of the times of flowing was constant. Both oils were subjected to a temperature of 32° F. When the pure oil was frozen it was more coherent and firm, and much lighter in colour; the adulterated sample was quite yellow. When the adulterated oil slowly became liquid a layer of yellow oil formed first, which was quite different in appearance from the other portion, and was evidently the adulterant.

While we cannot depend on any single test, the evidence afforded by several is often conclusive and satisfactory, and in this case it was acknowledged afterwards that cotton-seed oil was one of the adulterants.—*American Chemical Journal.*

ON A

DIFFERENTIAL RESISTANCE THERMOMETER

By T. C. MENDENHALL.

THE determination or registration of the temperature at a distant or not easily accessible point, is so extremely desirable that many methods for accomplishing this end have been proposed, and to some extent made use of during the past fifty years. Naturally enough electricity has been utilised in some way or other in the majority of these systems of telethermometry.

The requirements of the problem seem to be that the device or instrument used at the point, the temperature of which is to be ascertained, shall be of the greatest possible simplicity of construction, involving little or no motion in its parts, so that the liability to "get out of order" shall be reduced to the minimum; and that at the observing or registering station the necessary appliances shall possess a maximum of durability and simplicity—so that a minimum of time and skill will be demanded in making the observations. The whole system must be certain in its indications and correct within a reasonable limit.

The first of these conditions is apparently sufficiently well satisfied by the thermo-electric-junction, which has probably been more extensively made use of than any other form of electric thermometer. It renders necessary, however, the use of a comparatively delicate galvanometer, and as the electromotive force of a single couple is small (it is difficult to use more than one in general practice) the results are subject to considerable errors arising from unknown or neglected sources of electromotive force. This source of error becomes more important as the range of temperature measured becomes smaller, although it may be almost entirely avoided by care and skill on the part of the operator. The well-known resistance method of Siemens satisfies the same condition very perfectly, and is certainly capable of giving good results when skilfully applied, at least throughout moderate ranges.

The desire to possess some form of electric-thermometer which might be utilised in the study of certain problems connected with meteorology, especially the observation of soil and earth temperature, and the use of which would not demand greater skill than that of the ordinary meteorological observer, led to the device and construction of the instrument to be described which may be called a "differential resistance thermometer." It consists essentially of a mercurial thermometer, not unlike ordinary forms, except that the bulb is greatly enlarged so that the stem may have a diameter of something like a millimetre, and still leave the scale tolerably "open." In one of the instruments already made 1° C. corresponds to about 5 m.m. of the scale. Running down through the stem is a fine platinum wire about 0·08 m.m. in diameter. The lower end may be secured in the bulb so that it is kept straight in the bore of the stem, and at the lower end a heavier wire is sealed in the glass so that metallic contact can be made with this wire both at the upper end and through the mercury at the lower. It is evident that the resistance between these two points will depend largely (but not entirely) on the length of the platinum wire which is above the mercury in the tube, and this will depend on the temperature to which it is exposed. When this temperature rises the resistance is decreased by an amount equal to the difference between that of the platinum wire which disappears and that of the mercury which takes its place—less the increase in the resistance of the wire and mercury due to increase of temperature.

Let l = length of platinum wire exposed at o°.

s = resistance per unit length (= length of 1°) of wire.

g = resistance per unit length (= length of 1°) of mercury.

k = temperature coefficient of platinum.

h = temperature coefficient of mercury.

R_o = total resistance at o°.

Rt = resistance (including all) at $t°$.

Then—

$$Rt = R_o - \{ s(1-kl) - g \} t - (ks - gh)t_2. \qquad (1)$$

This equation is not quite rigorous, but the approximation is very close. It is of the form—

$$Rt = R_o - Bt - Ct_2. \qquad (2)$$

The simplest and best way of dealing with it is to determine the constants of the equation (2) by a series of observations, making use of the method of least squares. From the result the resistance for any degree of temperature may be calculated, or better, a curve can be constructed from which the temperature corresponding to any resistance can easily be read.

The advantage of this method over the use of a simple resistance coil is that the change in resistance accompanying a given change in temperature is much greater, and in fact it may be made as great as one desires. As a result the telephone may be substituted for the galvanometer in the resistance measurements, thus greatly simplifying the apparatus as well as increasing the rapidity with which observations may be made; or if preferred, a much less sensitive galvanometer may be used. It also possesses the very great advantage of allowing an increase of delicacy as the range of temperature decreases. For earth temperatures this is very desirable, and it will easily be seen that thermometers of this kind can be constructed for a few degrees of range, with which, by comparatively rude processes, the measurements may be correct within a very small fraction of a degree. For use in earth temperature measurements, the thermometer will be inclosed in a strong brass tube for protection, and the connection with the point of observation made by means of a cable of heavy copper wire. The cable will of course form a part of R_o in equation (2), but as it is a constant, the substitution of one cable for another, if necessary, will affect the position and not the form of the calibration curve. Its resistance must be small, relatively, and the influence of temperature upon it may be neglected.

With this device a temperature observation may be taken in less than a minute, no time being consumed in the preparation of liquids of known temperature at the observing station as in the use of the thermo-junction or the resistance coil.

THE OPTICAL PROPERTIES OF MALIC AND TARTARIC ACIDS.

By LOUIS BELL.

Among optically active substances these two acids have long been recognised as showing remarkable and inexplicable peculiarities. Much alike in chemical character, their optical properties are in most respects identical. Both show an increase of optical activity with a rise in temperature or with a decrease of concentration; both, in strong solution or at a low temperature, show a tendency to reverse the normal direction of optical rotation, and finally, under proper conditions, both actually reverse this direction, lævo-malic acid becoming dextro-rotatory, and dextro-tartaric acid becoming lævo-rotatory. Furthermore, each exists in a form itself optically inactive, but which may be split up into two forms, crystallographically enantiomorphous, and possessing optical activities sensibly equal and opposite.

This fact was shown for tartaric acid by the classical research of Pasteur,* while Bremer† extended it to malic acid. The optical properties correspond to the crystalline form so distinctly as to make it evident that the molecular structure which produces optical activity also induces crystalline asymmetry.

Both these acids also exhibit variable and anomalous rotary dispersion; tartaric acid in a very marked degree. In all respects their optical behaviour is so nearly identical that facts established by investigation of the one will uniformly be true of the other.

To explain some of these peculiarities, and in particular to assign a cause for the reversal of the direction of rotation, a phenomenon which implies some profound physical change, the following inquiries have been instituted.

The property of twisting the plane of polarisation is almost certainly due to some condition of asymmetry, either molar or molecular. In crystals it is always associated with enantiomorphs; in liquids it must be due to asymmetrical grouping or asymmetrical configuration of the molecule itself, while in gases it is quite certain that only the latter cause can operate.

In any case a change in the direction of this twisting is a change not of degree but of kind, and must involve an altered configuration of the material system upon which the ether waves impinge. In case of liquids Le Bel‡ has shown optical activity to be associated quite

* *Ann. de Chim. et de Phys.*, (2), xxiv., 442.
† *Ber. d. Deut. Chem. Ges.*, xiii., 351.
‡ *Bull. Soc. Chim.*, xxii., 337.

constantly with the presence of an asymmetrical carbon atom.

In the consideration of malic and tartaric acids the increase of specific rotation on dilution calls for careful attention. It was first investigated by Biot in case of tartaric acid, but all that he could offer by way of explanation* was the extraordinary hypothesis that the acid impressed its optical properties on the whole mass of water with which it was mingled. In a problem essentially dynamical this sort of explanation can have but little weight, and the solution must be sought elsewhere. It is evidently connected with the reversed rotation into which it gradually passes, and this in turn must plainly be associated with some change either in the molecules themselves or in their form of aggregation. Given a number of molecules twisting the plane of polarisation in a given direction, and there are four classes of causes which could reverse that direction:—1. Change of configuration of the molecule itself. 2. Formation of a hydrate or other chemical compound. 3. Building up of crystalline forms. 4. Formation of a polymeride rotary in the opposite sense from the free molecules. It is well to discuss these possibilities in order.

1. It does not seem probable that such a change could be produced by simple dilution, unaccompanied as it is by any marked thermal effects. Further, we know that the change can be produced, as when racemic acid is prepared from dextro-tartaric, but it is by no means readily effected. To form racemic acid in the way mentioned requires heating with water in sealed tubes for many hours to a temperature of 175°.† If such treatment is required to produce a lævo-rotatory modification of dextro-tartaric acid, it is highly improbable that it could be effected by any ordinary change in temperature or by any possible amount of dilution. And if the changes in temperature which produce such a marked effect on the optical activity do so by a change of configuration,—*i. e.*, from dextro to lævo forms, tartaric acid should crystallise in right- or left-handed hemihedral forms according to temperature. But such is not the case.

2. The hypothesis of a hydrate is at least quite plausible, and seems to have been the one tacitly adopted by many investigators. Biot in his later papers seems to have been inclined to accept it. The existence of a hydrate would explain most of the facts observed, and at first sight would appear very probable, but a close examination shows that no hydrate is formed.

In the first place hydrates are uniformly produced with evolution of heat, and in the case of one of the acids in question (racemic acid) the amount of heat given out has been accurately measured by Berthelot.‡ Hence we are justified in concluding that, if the dilution which so increases the specific rotation of tartaric acid is accompanied by the formation of a hydrate, it must also be accompanied by an evolution of heat. On the contrary, diluting a concentrated solution of tartaric acid causes a slight but unmistakable fall of temperature,—the uniform sign of chemical decomposition or physical disintegration. This point was demonstrated in the following way:—A small gas-washing bottle was fitted with a very sensitive thermometer passed through the rubber stopper which closed the lateral opening at the bottom. Enough distilled water to cover the bulb of the thermometer (usually 20 c.c.) was then poured in, and the contraction in the cylinder was then closed by means of a rubber stopper fitted on the end of a glass rod. About 15 c.c. of the solution to be tested was then placed in the upper part of the vessel, and the mouth was closed by a rubber stopper slipped over the rod before mentioned. Thus tightly closed, the whole apparatus was immersed in water for some hours. Finally, without taking the vessel from the water or disturbing it in any way, the glass rod was slipped upward far enough to remove the stopper from the contraction and allow the solution to run into the water. Solutions of tartaric and malic acids of from 20 to 40 per cent were thus tested, and falls of temperature of from 0·1° to 0·2° were observed. The same is true of solutions of various salts, but the fact is none the less conclusive against the formation of hydrates of the above acids.

Again, since a hydrate is a definite chemical compound, after a hydrate was formed we should expect a condition of comparative stability to be reached, but in tartaric acid there appears to be no such definite compound completed.

Finally, the most characteristic of the optical properties of these acids—*i. e.*, reversal of the direction of rotation by change in temperature—was discovered by Biot* in amorphous solid tartaric acid, in which case, from total absence of water, the possibility of a hydrate is obviously excluded. Biot had foreseen that a solution of tartaric acid would probably become lævo-rotatory if a sufficient degree of concentration could be reached, but had sought for the complete phenomenon in vain, till he found its analogue in the behaviour of melted tartaric acid, which on cooling down passes—like the solution as it is concentrated—through decreasing rotations into a lævo-rotatory amorphous solid. I have recently succeeded in obtaining slight lævo-rotation from a concentrated solution in 95 per cent alcohol at −15°.

Biot, throughout a most careful and exhaustive series of papers covering literally hundreds of pages of the *Annales de Chimie et de Physique*, was misled by the old formula of tartaric acid, ($C_8H_8O_{10}+2H_2O$), which represented it as containing water. Consequently he makes use of this hypothetical water even to explain the properties of the melted acid. His experiments, however, were very careful and elaborate, and his papers, scattered through the third series of the *Annales*, cover most of the facts concerning rotary polarisation.

The hypothesis of a hydrate being thus excluded, the next possibility is the formation of crystal molecules. This hypothesis was suggested by Dubrunfaut, Erdman, and Bechamp,† to account for bi-rotation in milk-sugar. For several reasons, however, it is not applicable to the present case. Whatever may be the nature of the modification which reverses the rotation in malic and tartaric acids, it certainly has a rotation direction opposed to that of the free acid. But malic acid shows little tendency to crystalliise in any form whatever, and the crystals of tartaric acid correspond in optical character to the solution. Hence any structure that could fairly be called a crystal would not probably show any tendency to reverse the rotation. Further, the formation of crystals would necessitate a change in optical character more rapid than that observed, as will be shown later.

From the consideration of these facts it appears that while the observed facts can hardly be accounted for by the formation of true crystal molecules, a quite similar phenomenon—the formation of a polymeric modification—may prove to be a sufficient explanation.

Such a hypothesis, in the first place, explains and agrees with the phenomena observed. Consider the case of a solution of dextro-tartaric acid, or, since the changes are here more rapid, of lævo-malic acid. As the concentration increases or the temperature falls, let a dextro-rotatory polymeride be formed. It is evident that the first effect would be to counteract the original rotation, and there must occur precisely what does occur in the acids in question,—a lessening of the initial specific rotation by an increase in concentration or a fall in temperature.

Breaking up of this polymeride by dilution or heating would obviously reproduce the same series of phenomena in the reverse order.

(To be continued.)

OBITUARY.

JAMES APJOHN, M.D., F.R.S.

WE regret to announce the death of Professor Apjohn, which took place on the 2nd inst. at his residence, South Hill, Blackrock, Dublin, at the ripe and honoured age of 91 years, having been born in 1794, in the parish of Grean, County Limerick. He was educated at the Diocesan School, Tipperary, from which he entered Trinity College, Dublin, in 1814, where he distinguished himself during his undergraduate course, amongst other honours obtaining a scholarship in 1816. He took his M.B. in 1821, but all his tastes and sympathies were with the experimental sciences, and in 1825 he was appointed Lecturer in Chemistry to the Medical School, Park Street, which school he actively co-operated in establishing in conjunction with Sir Henry Marsh, Dr. Graves, Dr. Jacob, and Mr. Cusack. Dr. Apjohn's reputation as an accomplished chemist was speedily established, so that in 1828 he was elected to the Professorship of Chemistry in the Royal College of Surgeons, Ireland, where his celebrity as a lecturer attracted students from all parts of the United Kingdom. In 1841 he was appointed by the Board of Trinity College, Dublin, Lecturer on Applied Chemistry, and in 1850, the Chair of Chemistry in the University becoming vacant, he was unanimously elected to fill it, the Professorship of Mineralogy being subsequently added. As a chemist, practical and theoretic, Dr. Apjohn has long held a foremost place. In 1853 he was unanimously elected a F.R.S. From time to time he has written numerous original memoirs on various subjects connected with chemistry and general physics. In 1837 he obtained from the Royal Irish Academy the Cunningham Gold Medal for an essay on "A New Method of Investigating the Gaseous Bodies." In 1874 he resigned the University Professorship, and a few years later he retired from all professional occupation. As years went on his well-known face was but seldom seen except by those who visited him in his own home, though he continued to enjoy uninterrupted good health till within a few weeks before his death, up to which time it may be said of him "his eye was not dim, nor his natural force abated," though he had long outlived the years allotted to man. With him has passed away one of the most upright and honourable of men, whose noble intellect for nearly a century shed lustre on the country of his birth.

CORRESPONDENCE.

PURIFICATION OF AIR.

To the Editor of the Chemical News.

SIR,—At the Royal Society, this afternoon, Dr. E. Frankland mentioned the interesting fact that air passed slowly through a 2-foot tube was found to be free from micro-organisms, though still containing (as shown by the optical test) an abundance of suspended matter. I venture to think that this difference in the behaviour of different suspended particles may be chiefly due to difference in their elasticity. The extremely fine particles suspended in air doubtless share in the rapid internal movements of that gas, and in passing through a tube the suspended particles must be repeatedly dashed against the sides. A particle of quartz or marble dust would rebound from the sides of the tube and be again suspended in the air. But how about the micro-organisms? We know that if we were to throw against a wall a handful of billiard balls and turnips, the first would return, while the turnips would lie at the foot of the wall. May it not be a similar action which keeps the inorganic dust suspended while the organic comes to rest?—I am, &c.,

R. WARINGTON.

Harpenden, June 10, 1886.

ESTIMATION OF POTASH.

To the Editor of the Chemical News.

SIR,—In the CHEMICAL NEWS, vol. liii., p. 202, appeared a paper by Mr. Gladding, which was read at the meeting of Official Agricultural Chemists at Washington, Sept., 1885, and which refers to a method proposed by me (CHEM. NEWS, vol. xliv., p. 130) for estimating potash as platinum salt in presence of sulphuric and nitric acids. The essential feature of the method consists in washing the K_2PtCl_6 with a strong solution of NH_4Cl, which has previously been saturated with the small quantity of K_2PtCl_6 it is capable of dissolving.

I am pleased to see the method has been found by Mr. Gladding to yield very satisfactory results; when I published it, and, indeed until quite recently, I was not aware any other chemist had suggested the use of NH_4Cl for washing the precipitate. Lately, however, I noticed the following passage in your work "Select Methods of Analysis" (1st Edition), p. 13, under Separation of Potassium from Sodium.

For separating potassium from sodium in presence of sulphuric acid Finkener proposes the following:—Add hydrochloric acid to the aqueous solution to be analysed, then solution of chloride of platinum until the liquid is deep yellow. Add water sufficient, when boiling, to dissolve the double salt precipitated; evaporate to syrupy consistence, but not dry; extract and wash on a filter with a mixture of alcohol (sp. gr. 0·8) 2 volumes, ether 1 volume. Wash well with solution of chloride of ammonium; this decomposes the sulphate of sodium and allows it to be washed away. The filtrate, alcoholic extract, and washings contain the sodium. Heat the filter and its contents in a stream of hydrogen—a temperature of 240° suffices—extract the chloride of potassium with water, and weigh or titrate with silver solution.

It appears strange that Finkener, after recommending the treatment with NH_4Cl, should direct reduction of the K_2PtCl_6 in a stream of hydrogen, since this is quite unnecessary except as a control on the results arrived at by weighing the yellow salt.

In "Fresenius's Quantitative Analysis," 7th Edition, p. 409, the first and last portions of Finkener's method are given under his name; no reference whatever is made to the use of NH_4Cl.—I am, &c.,

DAVID LINDO.

Falmouth, Jamaica,
May 25, 1886.

AMERICAN MEDICINES.

To the Editor of the Chemical News.

SIR,—The sale of these in England is due to excessive advertising. A commonplace medicine is selected and receives some curious name. It then forms the basis of a little tale of fiction setting forth its fabulous virtues. These small pamphlets, thus charged with falsehood, are dropped into areas and slipped into letter-boxes. A demand for the medicine then arises. On a more limited scale various pharmaceutical preparations made in America are advertised in the medical journals, and find their way into prescriptions, to the discouragement of English Pharmacy.—I am, &c.,

CIVIS.

On Varieties of Starch.—Dr. F. W. Dafert.—The author has examined the starch of *Panicum candidum*. It produces instead of the ordinary blue a reddish brown colour with solutions of iodine.—*Biedermann's Centralbl.*

CHEMICAL NOTICES FROM FOREIGN SOURCES.

Note.—All degrees of temperature are Centigrade unless otherwise expressed.

Comptes Rendus Hebdomadaires des Séances, de l' Académie des Sciences. Vol. cii., No. 22, May 31, 1886.

Researches on the Densities of Liquefied Gases and of their Saturated Vapours.—MM. L. Cailletet and Mathias.—The methods which the authors describe are applicable to all gases whose critical point is higher than the freezing-point of mercury. In a graphic construction of densities each substance gives two curves which seem to coincide at the critical point. The author's experiments demonstrate that at the critical point the density of the liquid is equal to that of its vapour, whence follows a practical method of determining graphically the density at the critical point if the critical temperature is known. The expansion of a liquefied gas is greater than that of the gas itself.

Combustion and Formation Heats of the Solid Hydrogen Carbides.—MM. Berthelot and Vieille.—The authors have studied the most important pyrogenous carbides, naphthaline, acenaphthene, anthracene, phenanthrene, retene, diphenyl, dibenzyl, and stilbene, to which they have appended crystalline camphene. The formation-heat from the elements is negative for the polyacetylenic carbides, benzol, naphthalene, anthracene, phenanthrene, and acenaphthene. This circumstance is connected with the endothermic formation of their common generator, acetylene. The very character of these formations appears due to the fact that the acetylene and the carbides obtained by direct synthesis are produced by the union of hydrogen with gaseous carbon—an element of which carbon in its present forms represents merely the polymerised states, produced with a loss of energy.

Ammonia in Soils: Reply to MM. Berthelot and André. — Th. Schlœsing. — The author maintains his opinion that, generally speaking, ammonia passes from the air to the soil.

Influence of Magnesia in Portland Cements.—G. Lechartier. — The cements employed in certain cases which the author has examined were mixtures of Portland cement with magnesia, which behaves at first like an inert body. By slow degrees the magnesia becomes hydrated long after the cement has set, whilst it increases in bulk, producing an expansion and the consequent destruction of works the solidity of which appeared established. These destructive changes take place the more rapidly the more directly the water acts upon the cements and penetrates into their mass.

Theoretic Calculation of the Composition of Vapours, their Coefficients of Expansion, and their Evaporation-Heats. — M. Langlois. — The author's theory will be expounded in full at the meeting of the French Association at Nancy.

On the Diffusion of Heat and on Physical Isomorphism.—L. Godard. — The peculiarity observed by Melloni in rock-salt and by Magnus in sylvine belongs also to the isomorphous and anhydrous chlorides, bromides, and iodides. These bodies, which have the same chemical formula and which crystallise in the same system, possess the same physical property as regards diathermaneity, thus further confirming the analogy of physical properties presented by isomorphous bodies.
